Cultivation, as we understand it, is practically impossible once the bulbs are planted. Success can only be ensured by carefully selecting types that will be likely to succeed in such soils. The necessity of thus specialising certain bulbs for certain soils, &c., is a real one. Many bulbs that find the rainfall of the east coast of England insufficient will revel in the heavier rainfall of the west coast. On the other hand, they may grow well in moist valleys on the east coast and fail on a too well drained hillside on the west coast.

With a view to guiding those who contemplate planting a table has been prepared from which individuals may be selected which require similar conditions as to soil, moisture, season of planting, and height of growth, and be expected to hold a fair balance of growth with the grasses that would not exceed their own height at the time of flowering. The approximate height, colour, exposure, soil, time of planting, time of flowering, powers of producing seed, and the distance apart to observe in planting are given for each bulb.

The height of growth and time of flowering will guide the planter in choosing the turf sites for the plants. Close growing turf will only accommodate the bulbs of lesser growth and early flowering, whilst stronger growing turf, suggesting a fairly rich soil, will accommodate the taller and stouter types. Exposure, soil, time of planting, and distance apart are important, for without careful consideration of these points bulb cultivation is scarcely possible, whilst production of seed must also be considered. Those whose powers of seed production are described as good produce seed which may reasonably be expected to germinate where it falls, and such plants may be regarded as the best to naturalise, as they rarely fail to get established.

Many genera contain several distinct types which cannot be made to thrive in grass together, and it would save time, money, and disappointment if bulbs were rigidly selected to suit the soils, so that

they may really naturalise themselves and last for many generations unaided, rather than prepare soils by manuring, &c., to suit the bulbs. This latter is costly and troublesome, and effective only so long as the prepared condition may last.

Such preparation of the soil as may be necessary for the bulbs should be carried out in August, as by that time most will be ready to grow. The methods of doing this will vary with the nature of the soil and the rooting characteristics of the bulbs.

Light soils for alpine and Asia Minor bulbs, such as *Muscari*, *Galanthus*, and those bulbs of small stature which require a light and somewhat dry medium, need not be dug. A loosening of the soil, effected by working a digging fork below the turf layer as far as it will go—taking thin strips at a time to ensure a thorough loosening—will be sufficient, and they may be sown broadcast and dibbled in where they fall without further preparation beyond a layer of soil to rake over the holes when planted.

A well-prepared soil should be selected for bulbs of stronger growth, and rendered friable and accessible to roots by deep digging, the turf being

on a grass bank, the soil of which, though friable, should not be too dry. These species flower very early in the year, almost before grass begins to grow, so that the height the grass ultimately attains is not very important. The Iris leaves attain a great length after the plants flower, so much so that it is almost impossible for the grass on a bank to choke them.

Iris of the Persica group, such as *Heldreichi*, *Tauri*, *caucasica*, *sindjarensis*, and *tubergeniana*, may also be planted on a bank, but the soil should be so well drained that the grass would wither in dry weather in order that the bulbs may have a good ripening, and that their leaves, which do not grow very tall, may make headway. These Irises should not be planted deeply: their roots will find their way to a great depth in most soils and not feel the influence of drought. Irises of the juncea type, such as *Boissieri*, *tingitana*, and *filifolia*, require a warm position, the bulbs being planted 5 inches to 6 inches deep if the surface soil is friable. They can only be recommended for warm counties.

The Spanish Irises, now almost universally planted, can be got in a great variety of beautiful

CROCUSES (*CROCUS VERNUS*) NATURALISED. (From a photograph by Miss Willmott.)

stripped off for the purpose. If available some rough but decayed leaf-soil should be worked deeply into the soil, having regard to the fact that bulb roots feed much more deeply than most plants. If slugs, wireworms, or other depredators are noticeable, it is important that each bulb should have an envelope of sharp sand, as this effectively prevents their reaching the bulbs, except by the decayed stem, which should be cut, not pulled out and thus form a passage. Once planted and the turf relaid a roller may be passed over the site a few times to settle the soil and any slugs that may be in the turf. Rolling occasionally when the bulbs are resting will do much to reduce the slug plague. Any special conditions to observe in planting, such as depth, &c., will be found briefly noted in the table.

Three great genera—Iris, *Tulipa*, and *Narcissus*—cannot, for considerations of space, be treated in specific order like the smaller genera, but some idea of the requirements of the various types comprised in each genus may be gathered from the following notes.

#### IRISES.

The lesser bulbous Irises, such as *bakeriana*, *reticulata*, *Histro*, and *histrionides*, are only happy

colours, and may be grown in any light soil. Being tall, with erect, grassy leaves, they may be planted in almost any grass, but are better in the wild garden and grassy plots in shrubberies than for carpeting a flat piece of turf in the open. The one drawback to their cultivation is the untidy appearance of their leaves and stems after flowering, and on this account one would like them planted in a place somewhat removed from frequented thoroughfares where they could be visited when at their best. It would not be wise to cut the stems down, for a good deal of bulb building is going on even when half the length of the leaves is withered.

The English Irises require similar positions, but the soil should be stronger and decidedly damp. They delight in half shade, preferring places where the coarser Ferns delight to grow, such as a woodland glade and thin coppice. The flowers grow larger and last longer in half shade than in full sunshine, and the bulbs delight in the light leafy vegetable deposit generally found in such places. Even in well-managed borders their flowers are soon over in hot weather. The colours of varieties may be obtained from any bulb catalogue.

*Iris tuberosa* (the Snake's-head Iris), a flower many admire for its quaint colouring, will grow almost anywhere. It should be planted in big clumps for effect and in places where it is not likely to be trampled upon. Slugs and most rodents are fond of its tuberous roots. Early planting of all Irises should be a general rule.

## TULIPS.

Tulips cannot be naturalised with any degree of certainty, although they may last for a few years. Garden forms revert by degrees to their original types, but a number of species and a few varieties will find the conditions suitable. The soil for these Tulips should not be dry, hard, or too well drained, and soils of a sterile nature, in which fungoid growth revels, should be carefully avoided, for the roots of Tulips are fibrous and do not penetrate to the same depth as Irises and Narcissi.

Light soils supporting a short close turf will accommodate the dwarf Crocus-like Tulips from Asia Minor, &c., such as *persica pulchella* and *montana*. These flower early in the season and ripen quickly. One may plant them in places considered suitable for Irises of the reticulata group. Woodland glades and natural shrubberies, in which a layer of leafy deposit may be found, will grow *Tulipas saxatilis* and *sylvestris* and their varieties. Both these Tulips ramble about by underground offsets, a bulb forming at the extremity of each runner. They invariably succeed in well-sheltered sites where the sun's rays are tempered, but they succeed better without direct shade overhead. Frosts frequently spoil the flowers in the open border, and a sheltered position such as that described will suit them far better than an open exposure. They are very effective and strong, and worth every effort to

naturalise, as they are capable of producing delightful pictures.

The choicest border Tulips, such as *La Merveille*, *vitellina*, *fulgens*, *Picotée*, &c., should not be trusted to hold their own amid grasses unless the soil be of exceptionally good tilth, but such kinds as *macrospila* (crimson-scarlet and fragrant), most of the *Gesner* Tulips, *Tulipas carinata*, *maculata*, *viridiflora*, *oculis-solis*, and several of the European species may be planted in good soil in sunny positions, whilst the first-named (*T. macrospila*) will thrive for years in the poorest of soils and lose none of its beauty. It is exceptionally hard to kill. In the main, Tulips that grow well in cultivated shrubberies, where the conditions are invariably much worse than in open pastures, may be expected to give a good account of themselves, the one feature to observe being a fair balance of growth between the Tulips and grasses, a matter that can only be determined on the spot. Parrot Tulips are not very satisfactory under harsh conditions, but one of their parents, *T. cornuta*, may be grown well where any other Tulip manages to live.

## NARCISSI.

Narcissi are delightful in grass. A few, however, will not thrive there, being mainly garden creations requiring good cultivation to maintain their high standard, whilst a few of the heavy headed doubles, such as *Sulphureus plenus*, *Aurantiacus plenus*, and *Incomparabilis plenus*, spoil any good effect by flopping about in all directions after the first breath of wind. It is not possible to deal thoroughly with the hundreds of varieties comprised in this great genus, as their cultivation is simple and well understood, whilst many object-lessons such as those at Kew exist for all who desire to study the types that do best. A few general notes, however, may be helpful. All Narcissi thrive best in a damp

soil of good depth. A few types, such as *biflorus*, *stella*, *spurius*, the *Campernelle*, and the *Tenby Daffodils* maintain some vigour in drier soils, but for the majority a damp substratum, easily accessible to their roots, is essential. A light shade suits them all, and may be regarded as exceptionally advantageous to such types as *Barri*, *incomparabilis*, *Leedsii*, and their many varieties, whose coronas and thin petals wither badly under the influence of the April sun, spoiling them long before their season.

It may not be necessary to dig friable soils of good depth for their reception if the dibber penetrates easily, but in the majority of cases it will be found advisable to strip off the turf and dig deeply, as advised in preceding paragraph. A reasonable expenditure of time and trouble in soil preparation will save much trouble later on, and the bulbs will thrive all the better for it. Practically all the Trumpet Daffodils may be grown well in the open pasture, but the smaller growing sections, such as *moschatus*, *triandrus*, and *Bulbocodium*, cannot withstand drought, and grasses on wet sites soon choke them. Little colonies may, however, be established on the half clothed banks of small streams. Use the Creeping Jenny (*Lysimachia Nummularia*) to cover and protect them. *N. bulbocodium* type is strong enough to grow amongst grasses, and it withstands drought better than the others of its group, but none of these lesser Narcissi can be regarded as good plants for naturalising or grass planting, owing to the difficulty of balancing their growth with that of the grasses.

Early planting is of the utmost importance. It is quite a mistake to wait for the clearance lists of dealers before repurchasing stocks, as many of the bulbs so obtained have spent four or five months of their growing season in a warehouse. The best planting months are September, October, and November.

TABLE OF BULBOUS PLANTS, &amp;c., WITH CULTURAL DETAILS, FOR NATURALISING IN GRASS.

Plant.	Height. Inches.	Colour.	Exposure.	Soil.	Time of Planting.	Time of Flowering.	Seed (Production of).
Allium Moly	12	Yellow	Sunny	Common	September—November	June—July Spring April	Very good
„ neapolitanum	18	White	Various	Light and damp	August	"	Fair, but requires culture
Anemone spennina	6	Sky blue	Sunny	"	"	"	"
„ alba	6	White	Sun or shade	"	"	"	"
„ blanda	8	Rich blue	"	"	"	"	"
„ tanrica	8	White, sky blue	"	"	"	"	"
„ fulgens	12 to 18	Scarlet	Sunny	"	"	April—May	"
„ annulata	12 to 18	Scarlet, wh. eye	"	"	"	"	"
„ grecia	12 to 18	Dark scarlet	"	"	"	"	"
„ nemorosa	4 to 6	White	Thin woods	"	August—September	April	Good, and germinates well
„ alba plena	4 to 8	White	"	"	"	"	"
„ robinsoniana	4 to 8	Pale blue	"	"	"	"	"
„ alba	6	Yellow	"	"	September	May	"
„ Pulsatilla	6	Purple	Sunny	Damp limestone	Winter	April—May	Uncertain, and difficult to grow
„ sylvestris	12	White	Sun or thin woods	Light and damp	"	May	Fair, but requires culture
Barnardia scilloides	9	Rose	Sunny	Common	March—July, August	September	Very good
Bellevalia romana	12	Steel blue	"	Light	September	April	"
Bloomeria aurea	12	Yellow	Sunny; plant deeply in warm counties only	Light and dry	"	June	"
Brodiaea Bridgesii	12	Lilac-red	"	"	"	May—June	"
„ capitata	24	Violet	"	"	"	June	"
„ congesta	36	Pale violet	"	"	"	"	"

THE NYMPHAEA (WATER LILY) POND IN REGENT'S PARK. (Photograph taken September 1.)

## TOWN GARDENING.

WATER LILIES IN  
REGENT'S PARK.

**G**OOD lessons in town gardening may be learnt from the London parks, especially from Regent's Park, where Mr. Jordan, the superintendent, plants many of the best hardy flowers to show their beauty near the crowded and smoky metropolis. The Hollyhock border has been, as usual, a quaint picture, and the Water Lily pond proves a grateful relief from the gay masses of exotics and hardy flowers. This *Nymphaea* pond is a source of pleasure to Londoners, and shows a phase of flower gardening with which they are not familiar. The little colonies of crimson, yellow, rose, and other shades of Water Lilies are very bright when the flowers open wide to the sun, and the water-loving plants at the edge of the pool have quite a natural effect. The water garden in Regent's Park is undoubtedly one of its most interesting features, and one that other parks might copy.

### BULBOUS PLANTS FOR THE GREENHOUSE.

THERE are many bulbous plants suitable for the cool greenhouse or conservatory in early spring which will require but little warmth to have them in flower some weeks earlier than they would be when grown in the open ground. Though many of them do not last long, they come into bloom just at a time when they are most appreciated, and they occupy little room before they are in flower, while they can be turned out as soon as they are over. Quite a long list of useful subjects might be given. Those enumerated below are among the best. Of course, the Hyacinths and Tulips require to be renewed each year, but many may be grown on from year to year if carefully treated.

#### HYACINTHS.

In the culture of Hyacinths it is of the first importance to secure good bulbs to start with. It is not always the largest bulbs that prove the best, but smaller ones that are firm and well ripened are the most satisfactory, and varieties vary, some making much larger bulbs than others. For early flowering they should be potted as early as possible. Any ordinary garden compost may be used. In potting the crowns should be kept well above the soil, and the bulbs should not be pressed down, for if the soil is hard at the base of the bulbs, the roots, which start altogether, cannot penetrate and the tips get damaged, and the bulbs may be lifted out of the soil if very hard. After potting it is usual to stand them in the open and

give a thick covering of cocoanut fibre refuse or other light material. They may then remain until required for starting. When for early flowering they should have an inverted pot placed over each when first put into warmth, and these may be removed after the bulbs have made a good start. After they are well started, light and sunshine are of more importance than a high temperature. The number of flowers cannot be increased, but by liberal and careful treatment the individual flowers can be got bigger, and also the foliage. Liquid manure made from cow manure and soot is the best stimulant. I hardly need add that it should be made some time before required for use and allowed to settle down, so that it can be used in a clear state, but I find it most difficult to make many understand that the virtue lies in the "liquid," and not in the dregs.

*Varieties.*—The single varieties are the most satisfactory for pots, and I should select the following, which will be found very serviceable for general purposes. White: La Grandesse, Mont Blanc. Blush: Grandeur de Merveille, Leviathan. Pink: Norma, Princess of Wales. Red: Robert Steiger, General Pellissier. Yellow: King of Yellows, Yellow Hammer. Light blue: Czar Peter, Enchantress. Medium blue: Captain Boyton, Leonidas. Dark blue: Baron Von Thuyll, King of Blues. Purple: The Sultan, William I.

#### TULIPS.

These require similar treatment to Hyacinths. After the flower buds show a light sunny position will be more advantageous than much artificial

heat. For very early flowering the Due Van Thol varieties may be grown. These may be had in six different colours, but the flowers are small, and I should only recommend them for very early forcing. The Pottebakker, white, red, and yellow, are fine for pots, and force well. Other sorts specially worthy of attention are: Dusart, dark red; Cottage Maid, blush; Ophir d'Or, yellow; Proserpine, crimson, with a silvery shade; Thomas Moore, apricot; Vermilion Brilliant, bright crimson; Prince of Austria, orange-scarlet; Cerise Gris de Lin, buff; Princess Marianne, white; Non Tresor, yellow; Keizerskroon, scarlet and yellow; and Bride of Haarlem, carmine, feathered white.

The best double varieties are: Rose Blanche, white; Blanch Hative, white; Murillo, rose; Murillo, yellow; William III., orange-scarlet; Leo XIII., scarlet, with yellow centre; Queen of the Netherlands, white, shaded rose; and Rose d'Amour, rose.

#### LACHENALIAS.

These are very pretty for spring flowering, and come into bloom quite early without any forcing. After they have done flowering they may be gradually dried off and later on repotted, selecting the largest bulbs, and about six in each pot make a nice show. The varieties are not numerous, and all are pretty, but Nelsoni is the finest for pots, having long spikes of rich yellow flowers.

#### LEUCOJUM VERNUM (SPRING SNOWFLAKE).

When potted in the autumn and kept in a cold pit during the winter it will soon start away when placed in a sunny position in the greenhouse in spring.

STAR AND OTHER DAFFODILS IN GRASS LAND. (From a photograph by Miss Willmott. See page 196.)

**GLADIOLUS COLVILLEI THE BRIDE.**

This pure white Gladiolus is useful for pots. Strong bulbs will generally throw up two or three spikes of bloom, and the bulbs should not be too much crowded in the pots. Use a good loamy compost, and after they are potted they may be placed in a cold pit and started when convenient. Besides the above there are now several other very pretty early varieties, such as Blushing Bride, Pink Perfection, Peach Blossom, and Rosy Gem. After these have done flowering and are properly ripened off the largest bulbs may be selected for the following season, and if the smaller ones are planted out they will make good bulbs for further succession.

**IXIAS.**

We get a great variety of colours in these, and they are easily grown. They should be potted early in the autumn. Use a compost consisting of sandy loam and leaf-mould. If protected from frost it is better not to use any extra covering on the surface of the pots. They may be taken in and placed on a shelf or in any light position, and will come into bloom in time to succeed some of the earlier flowering bulbs. Of named varieties, Crateroides, Emperor of China, Humbert, Magnum Bonum, Excelsior, Elvira, Viridiflora, and Vulcan is a good selection, or mixed varieties are satisfactory.

**FREESIA REFRACTA ALEA.**

This may be grown under the same treatment as the Ixias and is one of the prettiest subjects for early flowering. It will be found very useful either for the conservatory or for cut bloom.

**NARCISSI.**

Formerly it was only those of the polyantha type that were grown in pots, and these are still very desirable, the Paper White and double Roman coming in very early, and of others such as Grand Monarque and Gloriosa are still among the best. There is a great advantage in getting these potted as early as possible. They may be stood in the open and have a good covering of cocoanut fibre refuse, and if the weather is not too severe they will start early. As soon as they show through the covering may be removed to a pit and taken into more warmth as required.

**DAFFODILS.**

The ordinary trumpet varieties are the most showy for the greenhouse, and all the newer and choicer varieties may be grown, but such as Emperor, Bicolor Horsfieldi, Princeps, Obvallaris, and Telamonius plenus make a good show. Potted early and kept in a cold pit until they are well rooted they may then be taken into warmth as required.

A. HEMSLEY.

**SOME NEW TRUMPET DAFFODILS.**

The last few years have shown a marked advance in many of our best hardy flowers, but I venture to say that no other family has so well rewarded the skill of the hybridist as the Narcissus. It is to a few of the novelties in the white and sulphur-coloured trumpet section that I wish to draw attention, as great strides have been made in these of late. The two most remarkable flowers which have as yet appeared are undoubtedly

*Peter Barr and Florence Pearson.* — The former I daresay many of your readers saw at the Drill Hall on April 8 last, and it has been fully described in THE GARDEN, while only those who were fortunate enough to be present at the last show of the Midland Daffodil Society saw the first and only flower which the latter has yet unfolded. The resemblance between these varieties is very close, but, as

shown, many keen judges were inclined to give the palm to Florence Pearson as being the most perfect flower. We have already been told that Peter Barr originated from Monarch and Mme. de Graaff, and, when visiting Lowdham in June, Mr. Duncan Pearson kindly showed me the solitary bulb of Florence Pearson and told me something of its history. The bulb is very large and massive, and was lifted in the hope that there would have been at least one offset large enough to detach. This, however, proved not to be the case, as, though several offsets had been made, not one

have yet to bloom. As exhibited at Edgbaston several of our best judges pronounced highly in its favour, while its refined shape and translucent texture were remarked upon by all.

Yet another beautiful trumpet Daffodil which we owe to Messrs. Pearson is

*Mrs. Hillhouse.* — This is a very refined bicolor, with a long pale yellow trumpet, and is perhaps best described as a glorified J. B. M. Camm. The segments are stiff and of good substance, while the whole flower lasts in good condition a long time, and the foliage is strong and broad. Mr. Duncan Pearson tells me that he has no record of its parentage. Exhibited at Birmingham in 1894 it gained a silver medal, and when shown before the Midland Daffodil Society in April last it deservedly gained an award of merit.

*Lady Audrey,* which gained an award of merit for Messrs. Barr at Edgbaston this year, is of singular beauty, and has well been said to be a smaller Peter Barr, though it seems hardly quite so pure in colour as that variety. It is of good substance, and the colour of both trumpet and segments is a pale lemon-white, while the base of the flower adjoining the stalk is splashed with a yellowish green.

*Warley Magna,* which was so well shown both at the Drill Hall and also at Edgbaston by Miss Willmott, is a very pure and chaste white Ajax. Although much the same colour as Peter Barr, it is smaller and perfectly distinct from that variety. The main feature of the flower lies in its trumpet, which is widely expanded and beautifully frilled.

*Queen Christina* is another variety which was exhibited in capital form this year. It is an enormous bicolor, with a short firm trumpet of sulphur-yellow, which is broadly expanded and turned round at the apex. The sturdy perianth segments are a feature of the flower, and in colour are a pale primrose. It is said to be a strong grower and will prove most effective in the border.

It proves of interest nowadays to turn to the report of the Daffodil conference, held on April 1, 1884, and compare the list of varieties there given with those of the present day. In the white or sulphur-coloured trumpet section there are nine varieties mentioned, in addition to the three old ones—*i.e.*, *N. cernuus*, *N. tortuosus*, and *N. albicans*—they are W. P. Milner, William Goldring, C. W. Cowan, Exquisite, F. W. Burbidge, Dr. Hogg, Rebecca Syme, *cernuus pulcher*, and Mrs. Burbidge. And, although these were in cultivation more than twenty years ago, they still find a place

in our gardens, and Messrs. Barr have only eliminated two of the varieties mentioned from their catalogue quite recently, these being F. W. Burbidge and Rebecca Syme. Of course, at the time of the Narcissus conference Mme. de Graaff had only been seen by a few, as in the description accompanying the coloured plate of that variety in Vol. LVI of THE GARDEN, Mr. Burbidge tells us that it opened its first flower in April, 1883. With the hosts of new seedlings which every year pour into our spring shows many of our best varieties are being rapidly eclipsed, but no one can complain of a plethora of what are called white Daffodils. Indeed, Mme. de Graaff is

THE NEW TRUMPET DAFFODIL MRS. HILLHOUSE.  
(MUCH REDUCED.)

was of sufficient size to be detached from the parent with safety. Although this beautiful variety will be many years before it can be seen in gardens, one is content to know that like many of the newer trumpet Daffodils it is a strong, robust grower, so that in the gardens of the generations to come it will no doubt prove of the greatest value. That the raiser of seedling Daffodils must have patience to ensure success is undeniable, and this is only a case in point, as seven years have elapsed since Mr. Pearson crossed Emperor with Mme. de Graaff—Florence Pearson being only one out of twelve other seedlings which resulted from the cross, and even now nine of these

the only old variety which will stand in comparison with the six new varieties, Florence Pearson, Peter Barr, Warley Magna, Queen Christina, Mrs. Hillhouse, and Lady Audrey.

ARTHUR R. GOODWIN.

### SOME RARE LILIES.

It is a matter for regret that with the exception of Japanese and a few other sorts used for forcing and cut flowers, the demand for the rarer kinds of Lilies has during the last few years considerably declined, and while during the time of 1880 to 1890 they enjoyed the greatest favour, and collections were grown in many private gardens, these lovely plants have to a great extent almost disappeared. The fault of this is perhaps mainly due to the trouble there is in establishing them permanently in gardens. Still, my experience is, although many Lilies require special though simple treatment, there are no real difficulties in the way of growing the hardy kinds. I knew an amateur at Catford who grew a collection of the best kinds of the Martagon group in a small back garden, and we have exchanged sorts, such as the now rare White Martagon Lily, *L. testaceum*, and *L. dalmaticum*; another amateur in a smaller garden in the apparently most unfavourable neighbourhood of Kentish Town had for many years such species as *L. bloomerianum magnificum*, *L. rubescens*, *L. Bolanderi*, and *L. Parryi* in rare perfection, and only lost them by discarding Rhododendrons and other protective shrubs. It should always be understood that as Lilies are forest plants, growing invariably on wooded hillsides and getting shelter from sharp wintry frost by the shedding of the leaves in the first instance and then shelter against spring frost and the burning rays of the sun, while they are not too moist at the time of rest. Most of the Martagon group should be planted as early as possible in autumn, and in a well-drained loamy soil; some like humus. They rarely grow to perfection and flower well the first year, and when once doing well they should not be disturbed for several years, not until they show signs of failing, when division and transplanting is absolutely necessary. I find that bulbs coming from clumps grown for several years in the same spot are the easiest to establish again, being invariably quite healthy. The most interesting Lilies will always be those belonging to the Martagon group.

*L. Martagon album*, of which two kinds exist, one, rather inferior, is found wild in mountain forests on the Continent; it has flowers of a pale lilac or white colour, heavily spotted with maroon. The better kind of White Martagon is an English garden form found mostly in the Western Counties. It is easily distinguished from the Continental form in the light green, rather stout stem, and broad, light green leaves and creamy white large flowers.

*L. Dalhansoni* is a hybrid Lily, the result of a cross between *L. dalmaticum* and *L. Hansonii*. It is tall, vigorous, with brownish purple-spotted flowers. This form was raised by Mr. Powell, and another form raised in Dutch gardens by Van Tubergen and named *L. Marhan*, differs only in the lighter colour of the flowers. Both are now very rare in English gardens.

*L. Berensii* is an exceedingly rare and lovely Lily, the result of a most successful cross between *Lilium testaceum* and *L. chalcedonicum gracile*. The foliage is rather long, the bulb being like that of *L. testaceum*, and the flower is large, brick red colour, and with the sweet scent of *L. testaceum*.

*L. jankaeum*, a rare, shy-flowering Lily, being in habit very much like *L. Martagon* (not *L. pyrenaicum*), with large yellow flowers.

*L. albanum*, which was supposed to be identical with *L. jankaeum*, is quite different; it resembles much more *L. carniolicum* in bulb and foliage, but the colour of flower is bright yellow and not brick red as in *L. carniolicum*. Both kinds are very rare, and the collected bulbs, which are very expensive, arrive usually in poor condition and seldom grow. Although both these kinds are worth growing, *L. jankaeum* is the showier of the two.

*L. Martagon fl.-pl.*, next to *L. tigrinum*, *fl.-pl.*, is the best double-flowering Lily, the colour being a deep purple, much in the way of *L. dalmaticum*, and perfectly double. I am not aware of ever having seen it in English gardens, but saw it last year in a continental garden, although only in small quantities.

*L. chalcedonicum punctatum*, much prettier, larger flowered, and deeper coloured than both *L. chalcedonicum gracile* and *Heldreichi*, and heavily spotted with crimson. Very rare.

*L. testaceum* or *L. excelsum* is a hybrid Lily which originated in a German garden, and is the result of crossing *L. chalcedonicum* and *L. candidum*. Unless some means are found to keep this Lily it will soon be a plant of the past. In Holland, where it was once grown in large quantities, it has

rather slender, 3 feet to 5 feet in height; the leaves are thick, deep green, and arranged in single whorls of six to eight. The flowers are drooping, larger than those of the rather small flowering *L. columbianum*. The segments are bright orange-red, with the points much deeper coloured, while towards the centre the colour is bright yellow, dotted with maroon. The flowers are also sweetly scented, reminding one of *L. Parryi*. As a late flowering kind it is a most valuable acquisition, and must be classed among the best of hardy Lilies.

*L. polyphyllum* is one of the most distinct of Himalayan species, and not difficult to manage, only the bulbs are not lasting; they flower at the most in Europe twice or three times and then disappear, but ripen seeds plentifully. The peculiar long pointed bulbs when imported are usually dried up on arrival. The foliage is light green, and the white or pale lilac flowers are spotted purple or cherry red.

*L. callosum* is a Manchurian Lily, and used to reach us sixteen or twenty years ago by way of Russia, and I flowered it several times. It is a slender growing species, with elegant small scarlet flowers on exceptionally long pedicels, reminding one much of *L. tenuifolium*.

*L. medeoloides* has very pretty bulbs with jointed, exceptionally long linear scales, almost pure white in colour, and turban-shaped brick-coloured flowers.

*L. pulchellum*, once very common, would be out of cultivation but for a recent reintroduction, however, under the name of *L. concolor*. It is very slender, with wiry stem and small erect bright scarlet and spotted crimson flowers.

*L. Kelloggii*, a beautiful new Lily, resembling in general character *L. rubescens*. It grows 3 feet to 5 feet in height, is of sturdy growth, and the sweetly scented flowers are turban-shaped and produced in a terminal raceme bearing from five to twelve. The segments are ob lanceolate revolute, 2 inches to 3 inches long, pale lilac, faintly tinged purplish blue, and spotted claret, with a central line of yellow, stamens brown; exterior purple with a shading of lilac, rather uncommon colour in Lilies. The shape and colouring of the flowers remind one of *L. polyphyllum*. Native of California. It was figured in THE GARDEN of May 11, 1901.

G. REUTHE.

LILUM KELLOGGII.

(Three feet to 5 feet high. Flower segments 2 inches to 3 inches long, pale lilac faintly tinged with purplish blue and spotted claret colour, with a central line of yellow; stamens brown.)

almost disappeared, and even in central Germany, where twenty years ago bulbs were thrown out in the road owing to their abundance, it is becoming very scarce. It is one of the best of Lilies, and large healthy bulbs will produce as many as fifty flowers of a distinct nanking colour sweetly scented similar to *L. candidum*.

*L. carolinianum*.—Until quite recently both *L. superbum* and a form of *L. pardalinum* were offered, and I even saw it figured in one of our leading works on Lilies, being nothing else than *L. superbum*, all under the first name. The plant, which I believe to be the true *L. carolinianum*, is now (the end of August) in flower. The bulb is similar to that of *L. columbianum* or *L. rubescens* and not rhizomatous, as in *L. pardalinum* or *L. superbum*; the stem is dark green, smooth,

### THE ROSE GARDEN.

#### IMPORTANT NEW ROSES.

A WELL-KNOWN rosarian writes and praises three new Roses raised by M. J. Pernet-Ducher, which are being distributed this autumn. M. Pernet-Ducher raised such beautiful Roses as Caroline Testout, Mme. Abel Chatenay, Marquise Litta, and many others.

MME. PAUL OLIVIER.—This is described as very vigorous, upright, with large bronzy leaves and long oval bud; the flower is very large, full, globular, and salmon, shaded with carmine-pink.

MONS. LEDE.—Also very vigorous and of branching growth, with fine deep green leaves, and very large, full, cupped-shape flower of a superb pink-carmine tint shaded with yellow. Very sweetly scented. Has a long season.

SENATEUR BELLE.—Very strong in growth, producing straight shoots; the leaves are light green, and the flower large, very full, and globular in shape. Its colour is described as rosy white salmon, the centre deep yellow, outer petals shaded with rosy carmine.

All three are Hybrid Teas.

#### WHITE ROSES NOW FLOWERING.

ELEGANT growth and total immunity from the marring effects of mildew, combined with fine

trusses of snowy white blossoms, are valuable traits in

## AIMEE VIBERT.

It is just now, in spite of incessant rain, delightful on pillars, and is one of our best white autumn-flowering Roses. It will blossom best from laterals springing from other laterals, so that in thinning it is well to remember this. We might add much to our knowledge of how to prune if we closely inspected during summer and autumn the various flowering peculiarities of the different tribes and noted them for future guidance. Really interesting groups of white Roses for autumn display could be arranged by planting pillars of Aimée Vibert either in the centre or over a large bed, and by using varieties such as Coquette des Blanches, which is next in order of vigour, followed by Boule de Neige, Baronne de Maynard, Mme. Alfred de Rougemont, and Mme. François Pitbet, mingled or in blocks. If space could be spared for two outer rings plant Souvenir de la Malmaison for one and Anna Maria de Montravel or Little White Pet on the extreme margin.

## PHILOMEL.

## BEST ROSES OF THE SEASON.

IN response to your note I send a list of the Roses that have done best this year in the Thames Valley (Sonning) and are still flowering freely.

*Marie Van Houtte*.—A glorious Rose in this village; its flowers this year have been superb for size and colour. All the plants have been full of bloom and are so still.

*George Nabonnand*.—One of the best Tea Roses ever raised.

## Anna Olivier.

*Mme. Yvonne Gravier*.—An almost unknown Rose, very distinct in colour, white, touched with pink, the petals coloured like some beautiful shell, sweetly scented, very free, and flowers abundantly in autumn. It is not what the exhibitor would call a full Rose, as when the flower expands it shows the centre, but for gathering and to have in the garden it is most valuable.

## Souv. de Catherine Guillot.

## Mme. Chedane Guinoiseau.

## Papa Gontier.

*Princess de Sagan*.—A glorious scarlet colour without purple in it.

*Viscountess Folkestone*.—Always good.  
Hon. Edith Gifford.

## Marquise de Salisbury.

*Antoine Rivoire*.—Another new Rose of beautiful colouring, salmon and yellow mingling. It is very free and good.

*Caroline Testout*.—This has been magnificent. The great fragrant pink flowers have been the admiration of many visitors. It is very lovely at this date (September 9).

## Mme. Hoste.

*Grüss an Teplitz*.—Delicious fragrance, good crimson colour, and in every way a free and robust garden Rose.

## Maman Cochet.

White Maman Cochet. Every one of these Roses is a great success, so free and as full of flowers now as in summer. Most of the above varieties have been recently described, so I have not given any description.

J. S.

## THE FRUIT GARDEN.

## MULBERRIES &amp; MEDLARS IN THE ORCHARD.

ONE'S enjoyment of the garden would be greatly increased if the orchard, which is so often thrust away into a remote corner, were brought into direct communication with it. How easily the trim lawn spaces might lead, through groups of flowering shrubs, to the rather rougher grassy orchard. How naturally the garden Roses and masses of free-growing cluster Roses would lead to their near relations the Pears and Apples and other fruiting trees of the great Rose order.

There is no need to make a definite break between the two; it is all the better not to know where garden ends and orchard begins. Towards the edge of the mown lawn there may already be trees of Red Siberian Crab and the handsome Crab John Downie, and the pretty little Fairy Apple, while the nearer orchard trees may well be wreathed with some of the free cluster Roses, such as Bennett's Seedling or Dundee Rambler.

If the orchard is of some extent its standard trees of Pear, Apple, Cherry, and Plum may be varied by groups of three or four bush trees or by some of the beautiful fruit trees of lower growth, such as Medlar, Mulberry, and Quince. There may also be brakes of cut-leaved Blackberry and a thicket of Cobs or Filberts, and on some one side or perhaps more a shady Nut alley. There is no need to be always mowing the garden orchard. One wide, easy grassy way might well be kept closely shorn, but much of the middle and side spaces had better not be cut until hay-time. For many would be the bulbs planted under the turf, great drifts of Daffodils and Spanish Squills and Fritillaries for the larger effects, and Colchicums and Saffron Crocus for the later months. If the grass was mown again in September, just before the Colchicums appear, it would allow of pleasant access to the fruit trees in the time of their harvest, and in those most interesting weeks just before the Apples ripen.

The usefulness of a small orchard when judiciously planted and well managed can scarcely be over-estimated, and every country house should possess one. To those who have families a small orchard is indeed a boon, and if planted with early, mid-season, and late varieties of Apples and Pears the happy owner is enabled to supply his children with delicious Apple puddings and pies for eight months in the year. Moreover, in plentiful seasons there are always more Apples, Pears, and Plums than can be used at home, and these if carefully picked and packed can be profitably disposed of at the nearest town. Then a small orchard can be tilled with the spade at small cost, and vegetables and choice small fruits, such as Strawberries, Gooseberries, and Black Currants, may be grown between the rows of fruit trees for several years, and thus the usefulness of the orchard is increased. In small gardens even space can generally be found for a small orchard, when a large one is quite out of the question.

## THE BEST EARLY PEARS.

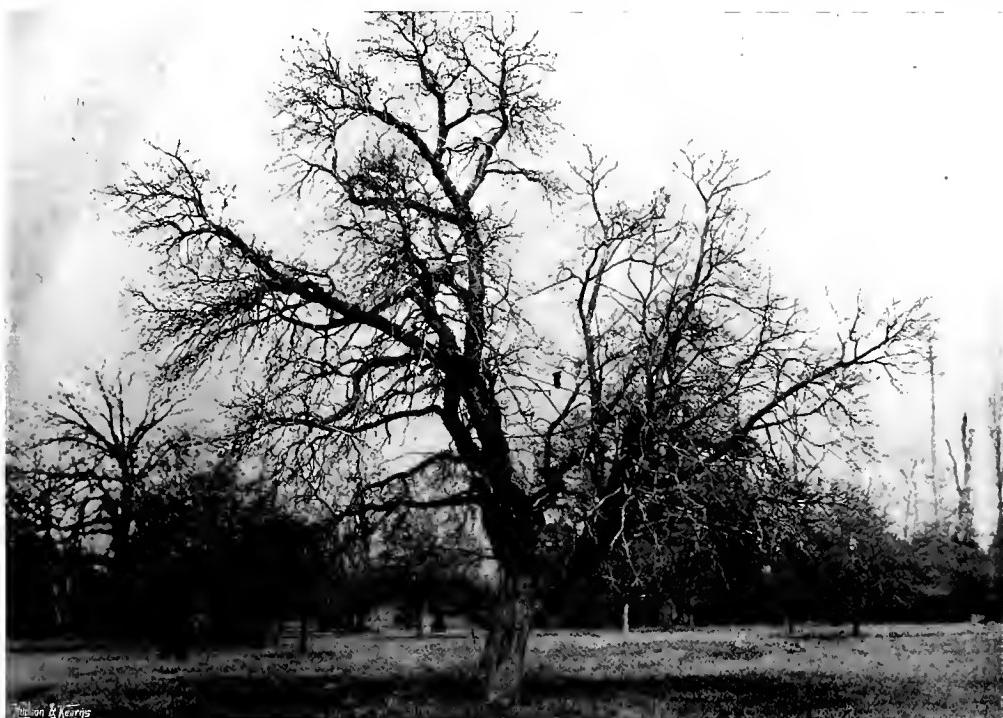

FOR a succession of early Pears, from the end of July to the end of September, the following varieties are amongst the best. It is generally known that the time during which early Pears are to be had in good condition for dessert is very brief. It is well to bear this in mind at the time of planting, as only a small number of those should be planted in any moderate-sized garden, one or two at most of a sort being quite sufficient. Early Pears are best picked from the tree a day or two only before they are required for dessert, or as soon as they show any traces of turning colour. In the case of the early Pear it is fortunate that the whole crop does not ripen at once, the process extending over a fortnight or longer, so that with the careful gathering of the fruit as it shows signs of ripeness—and this it invariably does on the south side of the tree first—a succession of fruit for a fair length of time is secured even from one good sized tree. These early sorts are nearly all good bearers.

## AUGUST PEARS.

*Doyenne d'Eté*.—This is the earliest to ripen of any Pear we have, and for that reason alone is worth a place in the garden. The variety is hardy and prolific, and although the fruit is small it is very acceptable at that season, being "sweet and refreshing" and pretty to look at, the colour being a lemon-yellow, suffused with red on the sunny side. It succeeds best as a pyramid on the Quince stock. It is ripe at the end of July.

*Citron des Carmes*.—This hardy little Pear ripens soon after the above. It is one of the most prolific of Pears and very sweet flavoured. It succeeds as a standard in the orchard as well as a bush or pyramid. The skin is greenish yellow, with a tinge of warm brown on the sunny side.

*Beurré Giffard*.—This handsome red cheeked early variety is indispensable. It succeeds the two foregoing in close succession.

A MULBERRY TREE IN THE GARDENS OF SYON HOUSE, BRENTFORD, ONE OF THE RESIDENCES OF THE DUKE AND DUCHESS OF NORTHUMBERLAND.

It is of medium size and delicious flavour, slightly aromatic.

*Juryonelle*.—Amongst early Pears this is the best known. It may be grown in the form of a bush or pyramid in the garden, or as a standard in the orchard, and where it is desired to grow it to the highest state of perfection as to size, it succeeds admirably planted against an east or west wall. The tree is hardy and strong growing. It is also one of those rare sorts that succeeds as well in the Midlands and the North, if not better, than in the South. The only fault we have to find with it is that young trees do not bear freely. It should be grafted on the Quince.

For the latter end of August one of the most satisfactory is

*Burré de l'Assomption*.—This is free growing, free cropping, and handsome. When eaten at the right moment it is of sweet and slightly aromatic flavour.

#### SEPTEMBER PEARS.

When we come to September Pears the choice is larger, and, as most of them are well known, and many of them described in the volume of THE GARDEN of last year under the heading of hardy fruit in season, a brief reference only will be made to them here.

*Williams' Bon Chrétien*.—This popular variety is indispensable. When grown on a wall the fruit may be had ripe late in August, but it is a true September Pear. It is well to have a tree or two on a west wall in order to have this Pear in season as long as possible, but the variety succeeds as well or better, especially as regards the latter quality, when grown as an espalier. This is the form of training I would generally recommend for the growth of this popular and valuable Pear.

*Brockworth Park*.—This greatly resembles the above, and by the novice may be mistaken for it. It is harder and the more prolific of the two, and succeeds well as a pyramid or as a standard in the orchard. A good market variety, but its quality is inferior to Bon Chrétien.

*Souvenir du Congrès*.—One of the handsomest and largest of Pears, fine for exhibition; the flesh is melting and the flavour refreshing. Should be grown on Pear stock.

*Triomphe de l'année*.—A comparatively new variety of great excellence. The tree grows and crops freely, the fruit is of large size, handsome, and the quality and flavour of the best.

*Marguerite Marillat*.—This is another variety of recent introduction and of Continental origin, and as a mid-September Pear has proved itself to be a real acquisition. It is one of the handsomest and most distinct, of large size, and the flavour is sweet. Towards the close of this month one of the best of all Pears is in season, I mean

*Fondante d'Automne*.—This is a delicious Pear, and must not be omitted from any collection. It succeeds well trained as an espalier or pyramid. It is also well worth growing against a west wall, as, grown in this position, the variety, unlike many Pears, is improved in size, quality, and flavour.

*Burré d'Amanlis*.—One of the most prolific and useful of September Pears, succeeds well as a pyramid or even as a standard in the orchard; should be grafted on the Quince. O. THOMAS.

#### NOTES FROM BATH.

The autumn flower show—so frequently marred the last few years by inclement weather—proved a decided success, and was visited by over 11,000 persons. Fuchsias, always a strong feature at this show, were splendidly exhibited, as also were Roses, considering the season. Especially worthy of mention was a magnificent bloom of Frau Karl Druschki, the new white H.P. I can vouch for this Rose being a good grower, as in July last I saw it doing well in Messrs. J. R. Pearson and Sons' nurseries at Lowdham, where it seemed almost to be a semi-climber. One of its parents is that grand Rose Caroline Testout, the other being Merveille de Lyon, and Mr. Peter Lambert, the raiser, has named it after the wife of the president of the German Rose Association. Another

feature of the show was a fine stand of garden Roses, exhibited by Messrs. Cooling, their Crimson Bedder, which is quite in the first rank of single Roses, being particularly striking. Hardy plants, more especially Phloxes and Pentstemons, were shown in wonderful variety by Messrs. Isaac House and Son, and the quality left nothing to be desired. Quite a break in Phloxes is Mme. Neera, one of Messrs. Lemoine's 1901 novelties, both spikes and flowers being enormous, and the colour a low tone of silvery white, edged with pale lilac. It is certainly a most striking variety. Subsequently I had the pleasure of seeing plants of it in Messrs. House's nursery, where I found that none were more than 2 feet high. Another very beautiful variety with huge flowers is Pharaoh, which is a pretty shade of lilac-rose, with a conspicuous white centre. But the finest of all these new varieties which I have yet seen is Roger Marx, a semi-dwarf grower, with most brilliant orange-scarlet, purple-eyed flowers. Mr. J. C. House considers this to be one of the finest Phloxes yet raised, and, after seeing a batch of it in full bloom at Westbury, I can thoroughly endorse his opinion; in fact, this one even surpasses Miss Pemberton in brilliancy of colouring.

Visitors to Bath cannot fail to notice the numerous parks—some of them only quite recently laid out—which almost surround the city. The climate is especially favourable to the growth of such things as Olearia Haasti, Berberis Darwinii, Sweet Bay, Veronicas (especially *V. salicifolia*), and other shrubs which are tender in the North and Midlands. One has only to visit the Botanic Garden to secure further evidence of this fact. On the occasion of my visit some of the Cistuses were still very beautiful, notably *Cistus algarvensis*, which forms a low bush of grey-green foliage, studded with bright yellow flowers, each of which has a brownish black spot in the centre; and *Cistus villosus*, with sage-green foliage, straggling habit, and flowers of a crimson-pink with yellow centre. Another lovely shrub which proves perfectly hardy is *Hydrangea alba rosea*, a very rare and beautiful plant, with crimson-pink and white flowers. One does not often meet with the tender *Cassia corymbosa* planted in the open garden, yet at the time of my visit it was attracting more attention from visitors than anything else, and its shining green foliage and the corymbs of rich yellow came in for general admiration. This shrub is a native of Buenos Ayres, and requires a warm and sheltered situation. Mr. Milburn's method of culture is to plant it out at the end of May in a compost of sandy peat and leaf-mould; at the end of September it is taken up, and, after the growths have been cut back almost to the old wood, it is wintered in a greenhouse.

Another uncommon feature in the Botanic Gardens was an elegant group of plants of the aromatic Californian evergreen *Diplacus glutinosus*, and bearing orange-red blossoms with orange centres. These plants, like the *Cassia*, are wintered in a greenhouse and planted out in early summer. In the rock garden there is always something to interest, and although summer had merged into early autumn, many charming plants were still in bloom. *Campanulas* were represented by a very beautiful dwarf form of *Campanula glomerata*, which was discovered a year or two ago growing wild at Sevenoaks by Lady Lushington. A new plant from Michigan, said to be a *Helianthemum*, but not yet named by the Kew authorities, was a mass of blossom. Unlike the other *Helianthems* this requires a damp spot and partial shade. The plant was a perfect mass of deep lemon-yellow flowers with reddish stems and narrow dark green foliage. Other plants in bloom included *Convolvulus mauritanicus*, the yellow flowered *Dianthus Knappii*, *Dianthus neanensis* from Roumelia, with grassy foliage and little white finely cut flowers; *Antirrhinum glutinosum*, the Himalayan *Sedum trifidum* with prettily serrated leaves and crimson-pink blossoms; *Asperula suberosa*, with woolly grey foliage, and small pink flowers shaped much like those of a *Bouvardia*; *Incarvillea variabilis* with a few rose-pink blossoms and Pyrethrum-like foliage; *Malvastrum*

lateritium, invaluable for clothing a dry bank; *Cyclamen neapolitanum*, just peering above the ground; and *Enothera speciosa rosea*, whose foliage had turned to crimson, and was considerably brighter than the rose-coloured flowers. In the bog garden the most conspicuous plant was *Senecio pulcher*, resplendent in purple-crimson and gold. Its flowers are really gorgeous, but the plant seems to be little grown, which is probably owing to its "miffy" character. Many other plants and shrubs were in bloom in this delightful garden, such as the Linums and graceful Sea Lavenders, Hypericums, Veronicas, with spikes of many coloured flowers, not to speak of hosts of Pentstemons, Japanese Anemones, Phloxes, and other gay autumn flowers. Though much of the interest attaching to this garden is due to its sheltered situation and the mild climate, the care and attention bestowed upon it by Mr. Milburn the superintendent has made it one of the most picturesque and at the same time instructive of our botanic gardens.

ARTHUR R. GOODWIN.

#### CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

#### THE PRIMROSE AND DARWINISM.

[To the EDITOR OF "THE GARDEN."]

**S**IR,—Allow me, please, to make a few observations on a review of the above book, which appeared in your columns on July 26. My delay in replying to it at an earlier date is due to its not having been brought to my notice until some little time after it had appeared, and when holiday time had already commenced.

The reviewer says that the title—"The Primrose and Darwinism"—is "scarcely appropriate, as 'Darwinism' is always understood to be Darwin's theory of the origin of species by means of natural selection." With respect to this point of appropriateness of title I venture to differ from his opinion. The leading points discussed in the book are the validity of Darwin's views on dimorphism and trimorphism in the Primrose and other flowers, and the general decided superiority of cross-over self-fertilisation in the floral world. These theories originated with Darwin. They form one of the pillars—and not an unimportant pillar—of his theory of natural selection. They are quoted at large, as supporting that theory, in his "Origin of Species." They have been adopted generally by his followers, and hence any evidence against their validity, which the Primrose amongst other flowers gives, is an evidence against Darwinism in one branch at least, and the title, therefore, is amply justified.

The reviewer states that I have "not proved experimentally" the value of the atmospheric agencies—sun, dew, wind, &c.—in the fertilisation of flowers. "His conclusions, therefore," he says, "though plausible, are *a priori* assumptions." I would ask what was the need for my experimenting to prove the benefit of the full play of atmospheric agencies, especially as I state that I distrust (and give grounds for my distrust) artificial experiments? I cannot see, even if I did experiment, how I could give stronger evidence than that which I have given from Darwin's own experiments with the Red Clover, the common Broom, umbels of Cowslips, and the Purple Loosestrife, &c., that sterility, from the partial or more complete exclusion of atmospheric agencies, is the result of the interposition of a close-meshed net. Such a conclusion when the flowers under the net are sterile, and other flowers closely outside the net are fully productive, and that, too, in cases when they could not be affected by any action of bees, is not based upon "*a priori* assumptions," but is a case of direct induction. Huxley says: "Science is nothing but trained and organised common-sense." All that is required in this case is, not additional experiments, but merely the

exercise of that scientific faculty. The last point that I wish to notice is the final remark of your reviewer: "It is a pity this book was not published in the seventh decade of the last century, instead of appearing nearly thirty years after the date of Darwin's book, viz., 1876."

Now the justification for "The Primrose and Darwinism" "appearing nearly thirty years after the appearance of Darwin's book" is that the errors of Darwin on the points mentioned are unfortunately still current amongst those who follow him, and not only amongst his professed followers, but with others who have not adopted his views in entirety. So current still are Darwin's views about the points mainly discussed in "The Primrose and Darwinism" that even Sir Joseph Hooker, as quoted in the preface of the book, enunciated Darwin's views on the heterostylism of the Primrose as valid before the august assembly which met at Oxford for the inauguration of the Darwin statue at the Oxford University Museum as recently as June, 1899. Many other instances of Darwin's views about heterostylism and the decided superiority of cross- over self-fertilisation

#### CUTTING THE FOLIAGE OF HARDY PLANTS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Under this heading your correspondent Mr. J. Crook (page 162) raises a most important question, which is certainly worthy of further discussion. I must confess that I have often hesitated as to whether or not it is correct to cut Pyrethrums and Delphiniums close to the ground soon after flowering. I think that little harm results provided that each plant is well watered and given a good dose of liquid manure immediately after being cut down. It must be remembered that this process amounts purely to a system of double cropping, in that the plants are expected to produce flowers and foliage anew, and if extra nourishment is not supplied they are bound to be weakened, and next year's growth suffers accordingly. Then, again, it is a great mistake to cut down the stems *immediately* after flowering and apply a mulch of manure, which is the stereotyped instruction usually given in nurserymen's catalogues. In the first place, supposing this plan is

as Messrs. Kelway would give this advice if it were harmful. At the end of August I paid a visit to Messrs. House and Son's nursery at Westbury-on-Trym, and was delighted to see a large patch of Delphiniums in full bloom. On enquiring from Mr. J. C. House as to the treatment to get this late blooming, I was informed that the first spikes of bloom were cut off before they had developed, in order that the plants might produce fresh ones in time for the autumn shows. I can testify to the excellence of the spikes, and the plants were vigorous, and certainly did not look weakened in any way by this method of treatment.

Certain plants suffer much more than others from bleeding when cut—notably, Rodgersia podophylla. Only this spring the leaves of this plant were badly injured by the late frosts, and I removed some of them in the hope that fresh ones would be thrown up. I was careful to give the clump some liquid manure, and eventually new foliage appeared, but not before the plant was severely weakened by bleeding for nearly a week at the places where the first leaves had been removed. On the whole, I feel bound to adopt the conclusion formed by Mr. Crook, i.e., that this cutting down process must be a check to the roots of the plants. It would be a great help if other correspondents would give their experience on this most interesting subject. As regards such things as Montbretias I can most thoroughly endorse all that your correspondent has written as regards the value of leaving the foliage to protect the roots. On cold soils in the Midlands one hears frequent complaints of these plants being killed during the winter, and the best way to prevent this is to leave the foliage intact and place some sods of peat over the clumps.

ARTHUR R. GOODWIN.

#### PLANTS FOR LIGHT SANDY BORDER.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I wish to make a border to grow herbaceous plants to bloom spring, summer, and autumn. Soil light sandy, depth about 18 inches, resting on gravelly sub-soil, situation high and open. There are no large trees near. Should like to know how to treat the soil and the best plants to choose.

PERENNIAL.

[The best way is to group the plants. Three rows would be ample in the width named, but of course they must be quite informal. This may be modified, however, by stretching a line lengthwise of the border, say through the middle, and by planting this first. Arrange the front and back groups in proportion. We advise this way because duplicates of some of the taller and bolder things for the back may not be necessary owing to the

great size of the plants, while quantities will be required of those in front. Again, by adopting this informal grouping convenient places will occur between the first and second rows for the introduction of such bulbous plants as Daffodils, Scillas, Muscari, Gladiolus, &c. As the width of border is not great we suggest only three of these informal rows, and these for convenience we will call "main rows." In this way the bulbous plants can be inserted here and there as opportunity offers and as a sort of filling up or finishing touch generally.

Of the things for the central row plant, say, three or four in each group. If the former, then a rough triangular plan will be best, directing the longer point of the triangle to the front and leaving the straight line facing the back row. This arrangement naturally appears formal when setting down the plants, but the growth soon alters it.

As to the treatment of the soil, which you say is light, dig it as deeply as possible. If very sandy and light a layer of quite fresh cow manure may be placed in the lowest trench and covered with soil. Then cover up with soil to 9 inches deep

AN OLD MEDLAR TREE ON FRINGE OF GARDEN. (See page 201.)

in the floral world generally, in the more popular botanical writings of to-day cannot assuredly have escaped the notice of your reviewer.

As Darwin's views on the points referred to above are still upheld by his immediate followers, and are still unfortunately misleading in some instances, as evidenced by their writings since 1876, even those who are not professedly his followers, it is evident that though it would have been better (and in this the author quite agrees with the reviewer) to have pointed out the errors into which Darwin fell at an earlier date, yet it is better for the true interests of botanical science to do so now rather than not at all. Moreover, it often requires, in this as in other fields of research, some time to detect errors, especially when they are covered by a great name. Still, when detected, as the writer of a review of "The Primrose and Darwinism" says (*The Pilot*, May 31): "If an observer carefully made and carefully recorded his observations, we feel sure that were Darwin alive he would be amongst the first to recognise it."

THE AUTHOR OF "THE PRIMROSE AND DARWINISM."

carried out, what takes place? Take, for instance, a Delphinium which has just finished blooming; the plant is full of sap, which is rushing up to the seeds in order to enable them to mature properly. No one could possibly think that this flow of sap can be suddenly diverted, and if anyone chooses to examine a Delphinium shortly after its *unripe* stems have been cut down they will find that for some time afterwards it will continue to bleed.

Mulching, too, is useless if, as is often the case, the ground around the plants whose stems have been removed is perfectly dry. To those who wish to cut their plants down I would say give not only a mulch and some thorough soakings of water but liquid manure as well. This year the water has not been required, but the manure has all the same.

Of course there is a great difference of opinion on this question of cutting down; indeed, Messrs. Kelway advocate for Delphiniums and Pyrethrums exactly what Mr. Crook condemns. Referring to these latter plants, Messrs. Kelway say: "The plants may with advantage be cut down after June, which proceeding will induce a more prolific succession of bloom through the autumn." Yet one would hardly suppose that such good growers

and add a further layer of manure of six months standing. By first taking out a trench 2 feet wide across the border and as deep as possible you will be able to treat the border as suggested. The double layer of manure is, however, only needful where the soil is excessively light. At the same time, the bottom layer of manure, placed low and trodden down, is most helpful, as it is cooling during dry seasons. Otherwise a heavy layer placed 12 inches deep would suffice in the ordinary way.

You will find the following a useful selection of plants, and we name those for the back row first. Six kinds of Delphiniums, such as Life Guardsman, conspicua, Lavender, Royal Standard, splendidissima, and Landseer, Kniphofia corallina, K. nobilis, and K. aloides, Aster Nova-Angliae pulchella, A. N.-A. rubra, and A. N.-A. W. Raynor, Helenium autumnale grandiflorum, Harpalium rigidum, Helianthus multiflorus and its varieties H. m. fl-pl., H. m. maximus, and H. m. Soleil d'Or, Bocconia cordata, Galega officinalis and G. alba, Anemone japonica and A. j. alba, Rudbeckia purpurea, Lupinus polyphyllus, L. p. albus, and L. p. bicolor, "Lilium tigrinum Fortunei," L. t. splendens, and "L. candidum, Lathyrus latifolius and L. l. albus, Spiraea Aruncus and S. astilboidea, Aquilegia chrysanthia, Heliopsis levis major, Echinops ruthenicus, Centaurea ruthenicus, Campanula lactiflora and C. l. cerulea, Bupthalmum cordifolium, Helenium grandicephalum striatum, Eremurus himalaicus and E. robustus, Eryngium alpinum, Anchusa italicica, Helianthus H. G. Moon and H. tomentosus. The above range from 4 feet to 5 feet high.

In the central portion you would be able to plant Peonies (these, however, in single examples), and in about six kinds, distinct shades. For other good things we suggest Gaillardias, Aster Amellus bessarabicus, A. A. Riverslea, Rudbeckia Newmanni, Achillea mongolica, A. The Pearl, Anemone sylvestris, Erigeron speciosus, Campanula carpatica, C. c. alba, C. rhomboidalis, C. glomerata dahurica, C. Van Houttei, Heuchera sanguinea, hybrid Columbines, Primula denticulata, P. cashmiriana, Thalictrum aquilegiforme, Incarvillea Delavayi, Veronica subsessilis, Lychnis haageana, L. chalcedonica, Erodium Manescavi, Agrostemma coronaria, Anthericums, Alstroemeria aurea, Geranium armatum, Geums in variety, Hemerocallis flava, H. Thunbergi, H. Middendorffii, Scabiosa caucasica and S. c. alba, Polemonium Richardsoni, Coreopsis lanceolata, Statice latifolia, and say six kinds each of single and double Pyrethrums, at least six kinds of Flag Irises, and the same number of Phloxes, together with Delphinium Belladonna, which is among the most charming of all flowering plants of medium growth. In the interstices between the groups you could plant English and Spanish Irises, Gladiolus, Narcissus in at least a dozen kinds, avoiding the double white Poet's kind, that is not likely to do much in your case. You may also make a show with a dozen sorts of border Carnations, selecting self colours and free and hardy as well as fragrant kinds.

Then for the front row you could have a great choice in dwarf Campanulas, such as pumila, alba, turbinata, G. F. Wilson, Hendersoni, and muralis, and in single and double Pinks, any of the dwarf Phloxes, also P. divaricata, P. ovata, P. amena, Lychnis Viscaria rubra pl., Arnebia echinoides, Onosma tauricum, Anemone apennina, A. fulgens, A. robinsoniana, Enothera macrocarpa, Arabis alpina fl.-pl., Gentiana acaulis, Armeria (Thrifts), Aquilegia cerasifera, Tiarella cordifolia, Primula cortusoides, Veronica prostrata, Zauschneria californica, Iris pumila in variety, I. nudicaulis, and many other things. Very pretty effects, too, are the outcome of introducing such bulbous things as Muscari, Chionodoxa, Crocus, Scillas, Fritillarias, the hardy Cyclamen, Iris Heldreichi, I. reticulata, and such like.

Finally, we can only suggest that you make a beginning on paper, executing a rough plan of positions, and in this way place your colours in some sort of order. If you retain the plan, you can as the subjects flower mark on it that number and so and so must change places in the autumn. In this way you will also note the

improvements likely to be made, also those seasons in which you have only a small display. In your soil you could plant the border in September or October, the latter suiting the greatest number of things named. Bulbous plants are marked with an asterisk.—ED.]

### FLOWER SHOW FANCIES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In answer to your correspondent, most certainly is the cultivation of a variety of plants, and as large a variety as possible, a perfectly legitimate form of gardening. My only contention is, that it does not always make for beauty, particularly in the small garden.

I should like to add that Mr. Barr's nursery must not be taken as an example of the "tailor's pattern-book." It is just the other way. He has ample space at his command, and he revels in the wild and free. It was, in fact, the sight of his rock plants—some of them quite homely things—so happily growing and spreading in masses, over and among the boulders of rock and stone, by the side of a running stream, contrasted with his "samples" of plants as seen in the same month at the Temple flower show that suggested my article. I made a bee-line from the Roses to the rock plants on purpose to see how these plantlets could be arranged for the best.

Mr. Barr's "pattern-book" (of course he must have one) will be found set out in the form of small pots, in the semi-shelter of open frames, where they look so tempting and are so portable that it is impossible to help running off with more sorts and kinds than one's rockery will hold. It is a question for individual taste whether we will do justice to a few varieties or take a greater interest and pleasure in sheltering a larger variety, which we shall have to keep thinning out, for most rock plants have a wonderful way of spreading.

F. A. B.

### GARDENING OF THE WEEK.

#### INDOOR GARDEN.

WINTER-FLOWERING ZONAL PELARGONIUMS.

PANTS of these may now be removed from the frames to the house in which they are to flower, and given a light and airy atmosphere with a night temperature of about 55°. The pots should be well washed, the surface freed from weeds, and the plants staged thinly. Let them have full sunshine, as a well-matured growth is necessary. Weak liquid manure and soot water should be given three times weekly. Show and fancy Pelargoniums that were cut back and have made new shoots about 1 inch in length should be shaken out and repotted in pots two sizes smaller than those they have been growing in. Good turf loam, charcoal, and sand, with some dried horse manure, form a good mixture. When potted place the plants in a frame and keep them near the light. Watch carefully for aphis, and destroy it at once or it will spread rapidly.

#### CHRYSANTHEMUMS.

It is too early to house the general collection. Much depends on the weather, but generally from the 25th of the present month until the first week in October will be early enough in most localities. Some varieties require moving inside earlier than the dates named. When the flowers begin to show their colour the plants should be removed under cover. Before their removal inside thoroughly examine the plants for mildew and dust with black sulphur. Remove all dead leaves and wash the pots clean. Avoid evercrowding. Allow the plants sufficient space for light and air to pass freely amongst them or the foliage is sure to spoil. Fumigate the plants three successive evenings to make sure all insect life is destroyed. Manure water must be given; that made from cow and sheep manure, with occasional applications of such

manures as Clay's Fertilizer and Peruvian guano for a change, in my opinion is the best. Great care must be exercised in feeding and watering at this season. Manures when in the hands of incompetent men will soon do irreparable damage. When the plants are housed give them abundance of air night and day in favourable weather.

#### AZALEAS.

These may now be moved inside as wet weather is likely to make the soil in the pots sour. If there is the least sign of insect pests thoroughly wash the foliage with soft soap and water, syringing afterwards with clean soft water. The pots should be well washed and the plants placed in a cool light and airy house. Soot water will assist in swelling up the buds. Camellias may be treated similarly.

#### PRIMULA SINENSIS.

These may be transferred into their flowering pots as desired, but never shift them until the pots are full of roots, and always pot the plants firmly up to the collar, being careful not to damage the leaves in any way. They should be placed in a well-ventilated frame and kept close to the glass. Primulas should be grown as hardy as possible, but must be protected against damp and cutting winds.

#### CINERARIAS.

will require similar attention as regards potting. The fact that Cinerarias are hardy and of rapid growth delays the potting too long. Immediately the pots are well filled with roots, shift on into larger sizes. As a general rule, 6-inch pots are large enough for decorative plants, but for large specimens 11-inch or 12-inch will be required. To grow them well one must always be on the alert for enemies; mildew is often troublesome. On its first appearance dust the foliage and soil with flowers of sulphur; for aphis vaporse with XL All. When tobacco smoke is employed, frequent light fumigations should be given. On no account may these plants be subjected to heavy smoking. For this operation the leaves should be quite dry and a calm evening chosen.

#### CALCEOLARIAS.

should be potted into 3-inch pots as growth demands. A rich, light, porous soil and efficient drainage are essential at all stages. Place the plants near the glass in a frame, and keep close for a few days, after which the more air that can be given the better. Water carefully and shade from the sun. Fumigation is a certain cure for green fly, but it is best used as a preventive.

#### SHADING MATERIALS.

The season is now nearly over for shading many plants, so that when the material is quite dry take down the blinds. Label and mend them now, as this will save much time and trouble when they are again required.

Wexham Park, Slough.

JOHN FLEMING.

### THE FRUIT GARDEN.

#### TREATMENT OF RIPE GRAPES.

THE air of houses containing ripe fruit should be dry and free ventilation given at all times when the weather is favourable, a little being left on at night when the weather is dry outside. If it is desirable to water inside borders before the fruit is gathered do this in the morning of fine days, and during damp weather keep up a circulation of warm water through the pipes, but guard against too warm a temperature, which would encourage red spider, detract from the colour of black Grapes, and cause them to shrivel. As soon as the fruit is gathered give inside borders a thorough watering with properly diluted liquid manure, which, if the foliage is healthy, will assist bud development. Thoroughly free the foliage from red spider and dust by syringing it with clear soot water or a suitable insecticide, such as soluble petroleum, if it is necessary, always bearing in mind that one of the most important points in Grape culture is to preserve the foliage in a perfectly healthy state until it falls naturally. Keep future lateral growths

moderately suppressed, and if the wood is not sufficiently matured maintain a warm airy atmosphere until it is satisfactory, when gradually admit air.

#### LATE MUSCAT HOUSE.

The fruit in this house is usually expected to carry on the supply until the beginning of the new year, and it should be now almost ripe; for unless it is perfectly ripened under the influence of the sun, together with a buoyant atmosphere, it will neither be of the best quality nor keep well. Therefore where the fruit is late, means should be taken to hasten its maturity by careful ventilation of the house, and by reducing the ventilation secure the sun's warmth. Use sufficient artificial heat to keep the night temperature from falling below 65°. During dull or wet weather keep the hot water pipes in the day time just warm, and at all times regulate the atmospheric moisture to suit outside conditions. The borders must always be uniformly moist, carefully avoiding anything approaching saturation. This will keep the roots active and prevent shrivelling of the berries. Keep young growths closely stopped, and in cases where a slight shading has been used in order to prevent leaf scalding it should now be removed. If wasps are troublesome cover the open spaces caused by ventilating either with wasp or hexagon netting.

#### VINES IN POTS.

Young Vines that were cut back before being started early in the year should be now placed out of doors in a favourable sheltered position, where they can be either secured to a wall or trained horizontally over a border covered with ashes to benefit fully by the sun's influence. The soil must not be exposed to a heavy rainfall, and remove the lateral growths entirely at the same time. Carefully preserve the chief foliage to assist in developing the buds and in ripening the wood, so essential to ensure fertility. When the leaves fall shorten the canes to suit the trellis upon which they are to be trained for fruiting, and well wash them with a suitable insecticide. As a precaution against bleeding the wound should be dressed with styptic, and the Vines be perfectly rested in a cool, freely ventilated house until required for forcing.

T. COOMBER.

*The Hendre Gardens, Monmouth.*

#### THE KITCHEN GARDEN.

##### FRENCH BEANS.

MAKE good sowings of Ne Plus Ultra and Canadian Wonder in 8-inch pots, also in heated pits, allowing sufficient room only for the growths to develop between the glass and the soil, as these will require all the light possible to ensure a free set. Use a compost of two parts fibrous loam, two parts leaf soil, and sufficient road grit to keep it open. As the young plants appear give air freely to promote a sturdy short-jointed growth.

##### LEeks.

The main crop should be well earthed up, but to ensure perfect blanching strips of brown paper should be loosely tied round them. Leeks like plenty of water at all seasons, and before applying the soil make quite sure that the roots are in a moist condition.

##### BEETROOT.

Owing to the frequent rains this crop has made more growth than usual, and the large growing kinds will in many cases become too large for general use if allowed to remain longer in the ground. This should be pulled and stored in a cool place in sand or ashes either in the open or root room, when it will keep just as well as if left till the generally recommended time for taking it up.

##### CELERY.

Continue to take advantage of fine weather for earthing up the plants. For some reason or other a large percentage of the earlier sowings have run to flower this season. Many complaints have reached me as to this from various parts of the country. This is no doubt owing to the check

it received after planting, as the bad weather experienced then would not allow it to start away into growth freely. Cold frames should now be got ready for receiving crops which have to be wintered in them, such as Cauliflowers, Lettuce, Endive, and Parsley. The soil used for this should not be too rich or the growth made will be too soft and sappy to stand through a severe winter. Allow a good distance between the plants, keep them near the glass, and plant firmly.

##### CABBAGE.

Make good plantations of spring Cabbage at intervals in various parts of the garden as the plants become fit. Allow a distance of 2 feet and 2 feet 6 inches, according to the variety, between the rows, and 12 inches from plant to plant. Water in to settle the soil about the roots, and place a small ring of finely-sifted cinder ashes around each plant.

##### TURNIPS.

These have seldom been better than they are this season. The quality, owing to the free, quick growth, is all that can be desired. When the bulbs are of fair size pull and store them thinly, placing sand or ashes between each layer. Make another good sowing on ground of a fine tilth, and strew the surface with soot and wood ashes.

E. BECKETT.

*Aldenham House Gardens, Elstree, Herts.*

#### NOTES FROM THE NORTH.

##### THE EDINBURGH SHOW.

In extent, in variety, and in quality generally the exhibition of the Royal Caledonian Society, held in the Waverley Market, Edinburgh, on September 10 and 11, left but little to be desired. When, however, one thinks of the splendid effect made by such exhibitions as the Temple show, the Shrewsbury floral fete, and other large provincial shows, one realises that the great Edinburgh horticultural exhibition was very much lacking so far as its general appearance was concerned. Examined in detail it was no doubt a splendid exhibition of British produce, but looked at as a whole it had a dull, uninteresting, and even patchy appearance. Down the centre of the market hall was arranged the least creditable feature of the show, namely, the specimen plants. These were not first-class, yet they had allotted to them the most important position in the hall. The groups of hardy flowers, of miscellaneous stove and greenhouse flowering and foliage plants, undoubtedly the most generally interesting exhibits in the show, were arranged, one might almost say hidden, around the sides of the hall. If at the recent show the displays made by Messrs. Cocker and Sons, Laird and Sons, J. Forbes, Cunningham, Fraser and Co., and others had been in the positions occupied by the specimen Crotons, Fuchsias, Dracænas, &c., how totally different and how much improved would the general effect have been.

It is gratifying to know that the earnest efforts of the council and committees are being rewarded. There were no less than 2,440 entries from 305 exhibitors, 125 of whom did not compete last year. In some cases, however, the exhibitors failed to come forward, the reason chiefly being due to the damage done to crops by the recent storm. There were no competitors in the nurserymen's class for the best collection of hardy flowers, those who had entered having withdrawn. The collections and the single dishes also of Apples and Pears were very poor, the fruits were small and almost colourless. All three prizes for the collection of twelve varieties of Apples came South, and two of them to the county of Hereford. For a similar collection of Pears, the prizes were again awarded to exhibitors from England. The first prize for a decorated dessert table also came South, Mr. Dawes, Ledbury Park Gardens, being the winner; he was, however, only third for decoration. There was only the narrow margin of half a point between the winning table and the second prize one arranged by Mr. D. Kidd.

The best feature of the show was undoubtedly provided by the exhibits of Grapes. The Muscats of Alexandria were not remarkably good; in fact, some were very bad, but the black Grapes were splendid. The varieties Muscat Hamburg, Mrs. Pince, Gros Colman, and Lady Downes were represented by some perfect bunches. One of the best bunches in the show was the first prize one of Lady Downes, shown by Mr. David Murray, Culzean Castle Gardens. It was not surprising to notice in the class for the best flavoured white Grapes that, out of seven bunches shown, five were Muscat of Alexandria. Worthy of note also is the fact that for the best flavoured black Grape the three prizes were awarded to bunches of Muscat Hamburg; Black Hamburg and Madresfield Court were the only other varieties shown in this class. The Grape which carries the best bloom would appear to be Cooper's Black, since the three prizes went to this variety in the class for black Grapes with the best bloom.

It is interesting to note that the first prize for a new Grape introduced since 1883 was given to Messrs. Buchanan, Kippen by Stirling, for their Diamond Jubilee. As shown here it was totally different from Cooper's Black, a variety with which its name has often been linked. The berries bore a greater resemblance to Madresfield Court than to any other variety, but they were larger and blacker. The second prize for a new Grape was given to the variety Prince of Wales, a sport from Mrs. Pince, sent out, I believe, by Messrs. Veitch of Chelsea. Only one bunch of the variety Lady Hutt was to be seen in the show, and Appley Towers was not represented at all.

Messrs. Rivers' exhibit of fruit trees in pots attracted much attention, and their dishes of orchard-grown Apples and Pears were immeasurably superior to those exhibited in the competitive class for similar produce. Messrs. Dobbie and Co., Rothesay, N.B., in their grand display of Dahlias had some new decorative varieties, semi-double, medium-sized flowers, splashed and striped with many colours, and which have the merit of lasting when cut. Messrs. Dobbie also showed a new Chrysanthemum, Horace Martin, a yellow sport from Marie Massee; Mr. John Forbes, Hawick, showed some grand Pentstemons; and Messrs. Croll, of Dundee, had masses of a lovely white Phlox, which was unnamed.

Of new plants we noticed Juniperus Richardii, a pretty conifer, represented by plants about 2 feet high. In colour the shoots are a light grey-green and dark green at the base. This plant was shown by Messrs. R. B. Laird and Sons, Edinburgh. Carnations Lady Nora Fitzherbert and Sir R. Walde Griffith were noticeable amongst Messrs. Laing and Mather's splendid group of Carnations. The first-mentioned is quite a dwarf plant, not more than 6 inches high; it is a seedling from Germania, and is equally adapted for greenhouse or bedding. The flowers are similar to those of Germania, large and very freely produced. Sir R. Walde Griffith is a lovely flower, a beautiful orange-scarlet colour. A good pale yellow border Carnation named Lady Stewart was shown by the raiser, Mr. John H. Cumming, Grantully Castle, Aberfeldy, and obtained an award of merit. Mr. Hugh Dickson, Belfast, obtained a first-class certificate for Rose Marchioness of Abercorn, a lovely flower of bronzy sulphur colouring. Messrs. D. and W. Buchanan had a most interesting collection of Grapes, containing several new varieties. One named Forth Vineyard, a good-sized round berry and large bunch, the committee considered meritorious, and would like to see it again. At the luncheon given to the judges, committees, and others, over which Mr. R. V. Mather most ably presided, Mr. Hugh Dickson, jun., of Belfast, voiced a thought that must often have been in the minds of many. He remarked that whilst the efforts of the visiting exhibitors were usually recognised and appreciated, those of the local nurserymen often were altogether forgotten. It is, however, to the help extended by local men that the Edinburgh show owes much of its attraction, and it is doubtful if they benefit to nearly the same extent as do exhibitors from a distance.

A. P. H.

## SOCIETIES.

### ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

The annual exhibition of this society was held in the Waverley Market, Edinburgh, on September 10 and 11. Despite the unsettled weather the show was well attended. The best feature of the exhibition was the display of Grapes, the black varieties being especially fine. Roses were very good, and the hardy flowers, too, considering the recent severe storm. The plants were not of particular merit, and the hardy fruit was small and colourless. Vegetables were well shown. Mr. Murray Thompson, S.S.C., the energetic secretary, was responsible for the arrangements. Notes upon the show, from a Southerner's point of view, appear in another column.

#### FRUIT—GARDENERS AND AMATEURS.

Dessert table, decorated with plants, flowers, and foliage: The first prize was won by Mr. James Dawes, gardener to M. Biddulph, Esq., Ledbury, Hereford, who gained 95½ points. The table was but thinly arranged with fruit, but it was none the less effective for that. The Grapes were fairly good, the variety Lady Hutt being shown, the Peaches were splendid, the Pears very good, the Figs also, while the Nectarines, Plums, and Melons were of the first quality. For decoration this exhibit was third, obtaining 15 points. Montrachets were chiefly used. Mr. D. Kidd, gardener to Lord Elphinstone, Carberry Towers, Musselburgh, won the second prize, being only half a point behind with 93. The Grapes were superior to those in the winning exhibit, the Pears were very good, but most of the other dishes of fruit were small. The first prize for decoration was awarded to this table, it gained 23 points. The centre piece was of Gloriosa superba, Francoea, Lily of the Valley, with a few beautifully coloured Rose buds, and the smaller glasses were similarly arranged. Mr. Robert Cairns, gardener to James Martin White, Esq., Balfriddery, was third, showing some good fruit. The second prize for decoration was awarded to Mr. William Smith, Oxenford Castle Gardens, with 17 points.

For a collection of ten dishes of fruit, Mr. James Dawes, gardener to M. Biddulph, Esq., Ledbury Park, Hereford, was first. The bunches of Muscat Grapes were very long but lacked finish. Peach Sea Eagle, Nectarine Stanwick Erluge, and Melon Ne Plus Ultra were good. Mr. David Murray, Culzean Castle Gardens, was second. He had a splendid Melon (Boyd's Eureka) and good Spencer Nectarine. Mr. Smith, Oxenford Castle Gardens, was third.

For a collection of twelve dishes of hardy fruit (Scotland only), Mr. James Day, gardener to the Earl of Galloway, was first. The fruits were of good quality, being well coloured but small. Mr. A. C. Binnie, gardener to Sir W. Gardiner Baird, Bart., North Berwick, was second, with very good specimens; Mr. William Harper, gardener to J. R. S. Richardson, Esq., Bankfoot, Perth, third.

For a similar exhibit, grown in an orchard house, Mr. James Beisant, Long Forgan, was first. He had good, well coloured Apple Emperor Alexander, Pear Souvenir du Congrès, Spencer Nectarine, and Large Early Apricot. Mr. James Dawes, Ledbury Park Gardens, was second, showing splendid Kirke's Plum, Barrington and Bymond Peaches, Humboldt Nectarine. Mr. R. Greenlaw, Kelwin, was third.

Twelve Peaches: First, Mr. Robert Glen, Larbert House Gardens, Stirling, with splendid Sea Eagle; second, Mr. J. K. Brown, Dunnikier Gardens, Kirkcaldy, with Barrington, very good; third, Mr. James Dawes, Ledbury Park Gardens, Hereford, with Barrington also. There were many other entries.

Twelve Nectarines: First, Mr. James Dawes, with fine Humboldt; second, Mr. T. Lunt, with good Pineapple; third, Mr. D. Murray, with the same variety.

Twelve Apricots: First, Mr. William Galloway, Gosford, with Large Early; second, Mr. George Mackinlay, showing Moorpark; third, Mr. A. C. Binnie, North Berwick.

Twelve purple Plums: First, Mr. A. Findlay, gardener to Count A. Munster, Uckfield, Sussex, with Kirke's; second, Mr. J. Dawes, Ledbury, Hereford; third, Mr. A. Harvey, Ayr.

Twelve red Plums: First, Mr. A. Findlay; second, Mr. R. G. Sinclair, Coryton Gardens, Drew; third, Mr. G. MacKinlay.

Twelve yellow Plums: First, Mr. George Mackinlay; second, Mr. James Gibson; third, Mr. M. Haldane, Beckenham, Kent.

Twelve Plums: First, Mr. J. Dawes, Hereford; second, Mr. John Cairns, Coldstream; third, Mr. J. McFarlane, gardener to Captain Grant.

Collection of culinary Plums: First, Mr. James Gibson, Danesfield Gardens, Bucks, with excellent Ardchuke, Pond's Seedling, &c.; second, Mr. A. Harvey, gardener to J. H. Houldsworth, Esq., Ayr; third, Mr. George Mackinlay, Wrest Park Gardens, Ampthill.

Collection of dessert Plums: First, Mr. George Mackinlay, Jefferson and Transparent Gage being the best dishes; second, Mr. A. Harvey; third, Mr. James Gibson.

#### GRAPEs.

Six bunches of Grapes: First, Mr. Thomas Lunt, Keir House Gardens, Dunblane, with almost perfect bunches, all splendidly finished. Black Hamburg, Madresfield Court, and Muscat of Alexandria were the varieties shown. Messrs. D. and W. Buchanan, Kippen, by Stirling, were a good second. Alicante was shown by them very finely, and the Muscats were also good. Mr. James Beisant, Longforgan, was third. There were three other entries.

Four bunches of Grapes: First, Messrs. D. and W. Buchanan, Kippen, with splendid Alnwick Seedling, Diamond Jubilee, Alicante, and Cooper's Black, all splendidly finished. Mr. James Day, Garlieston, was second, showing finely finished Muscat of Alexandria, and Mrs. Pince and Muscat Hamburg were good also; third, Mr. James Beisant, Longforgan.

Two bunches of Muscat of Alexandria: First, Mr. James Day Garlieston, with well coloured bunches; second, Mr.

D. Kidd, Carberry Tower Gardens, with not very shapely bunches; third, Mr. W. J. Green, gardener to Sir C. M. Palmer, Bart., M.P., Grinkle Gardens, York, with huge ungainly bunches.

Two bunches of Black Hamburg: First, Mr. Thomas Lunt, Keir House Gardens, with bunches of good size and well coloured; a good second, Mr. J. Fairholm, gardener to Mrs. Younger, Alloa; third, Mr. Robert Glen, Larbert House Gardens, Stirling, who also showed well. There were thirteen more entries.

One bunch of Muscat of Alexandria: First, Mr. J. J. Wann, gardener to Lord Balfour of Burleigh, with a good bunch; second, Mr. Green, Grinkle Gardens, York; third, Mr. R. Cairns, Balfriddery.

One bunch of Black Hamburg: First, Mr. T. Lunt, with a magnificent bunch of good size, large berry, and perfect finish; second, Mr. J. Fairholm, Alloa; third, Mr. D. Kidd, Carberry Tower Gardens, both of whom showed well. There were seventeen more entries.

One bunch of Alicante: First, Messrs. D. and W. Buchanan, Kippen, with a grand bunch; a very good second, Mr. John Leslie, Pitcullen House Gardens, Perth; third, Mr. W. J. Green, Grinkle Gardens, York.

One bunch of Alentejo: First, Messrs. D. and W. Buchanan, with a very large bunch, well finished, though of small berry; second, Mr. James Day, Garlieston, with a good bunch carrying a splendid bloom; third, Mr. T. C. Sutherland, Polmont.

One bunch of Gros Colman: First, Mr. R. Stuart, Thirlstane Castle Gardens, with a bunch of perfect finish; second, Mr. John Paterson, gardener to John Barry, Esq., Kirkcaldy; third, Mr. J. McPherson, gardener to Miss Raffin, Mayfield.

One bunch of Lady Downes: First, Mr. David Murray, Culzean Castle Gardens, with a beautiful bunch; second, Mr. D. Buchanan, gardener to Colonel the Hon. North D. Hamilton, Dally; third, Mr. D. Kidd, Carberry Tower Gardens, both showing well.

One bunch of Madresfield Court: First, Mr. Robert Glen, Larbert House Gardens, Stirling, with a splendid bunch, though the berries were somewhat red; second, Mr. T. Lunt, with a smaller, well-finished bunch; third, Mr. Shanks, Strathearn, Grahamstown.

For one bunch of any new Grape introduced since 1885, Messrs. D. and W. Buchanan, Kippen, by Stirling, were first with Diamond Jubilee; Mr. Thomas Lunt second with Prince of Wales (a sport from Mrs. Pince); third, Mr. D. Buchanan, Dally, with Diamond Jubilee.

For one bunch of the finest flavoured Black Grape: First, Mr. Thomas Lunt, with Muscat Hamburg; second, Mr. J. Beisant, gardener to Mrs. Armitstead, with the same variety; third, Mr. M. B. McDonald, Longwood Gardens, Longholt, also showing Muscat Hamburg.

One bunch of the finest flavoured white Grape: First, Mr. William Galloway, Gosford; second, Mr. John Potter, Whitehall, Cumberland; third, Mr. A. Angus, Motherwell, all showing Muscat of Alexandria.

Black Grape, for finest bloom: First, Mr. T. C. Sutherland, Polmont, with Cooper's Black; second, Mr. John Leslie, Pitcullen House Gardens; third, Mr. D. Murray, Culzean, both with the same variety.

#### APPLEs.

Collection of Apples: First, Mr. R. M. Whiting, Credenhall, Hereford, with fairly good specimens, Lord Suffield being the best; second, Mr. W. H. Tolhurst, gardener to A. D. Kleinwood, Esq., Bolene, Sussex, his Duchess of Oldenburg, very finely coloured; third, Mr. M. Roe, gardener to E. W. Caddick, Esq., Caradoc, Hereford.

Collection of Apples (grown in Scotland): First, Mr. James Day, Garlieston, with fairly good fruits; second, Mr. David Murray; third, Mr. D. Nicoll, Forganenny.

Six varieties of Apples: First, Mr. James Dawes, Ledbury, Warner's King and Tyler's Kernel being good; second, Mr. George Mackinlay, Wrest Park Gardens, Ampthill; third, Mr. M. Roe, Caradoc Gardens, Hereford.

Six dessert Apples: First, Mr. R. M. Whiting, Credenhall, Hereford; second, Mr. James Day. There were no entries in the class for a seedling Apple not in commerce.

The chief prize winners in the classes for single dishes of Apples were Messrs. R. M. Whiting, M. Roe, James Dawes, John Lee, William Galloway, Alexander Findlay, D. Murray, Adam Shakelton, A. Dickson, Andrew Harvey, James Day, R. Lawrie, R. G. Sinclair, D. Buchanan, M. M. Haldane, W. H. Tolhurst, J. Paterson, R. R. Greenlaw, George Edgar, James Beisant, Alexander Lauder, and John Cairns.

#### PEARs.

Collection of Pears (grown in Scotland): First, Mr. William Galloway, Gosford, Marguerite Marillat, Souvenir du Congrès, and Dr. Jules Guyot were the best; Mr. R. R. Greenlaw, gardener to H. J. Younger, Esq., Kilnum, was second, and Mr. David Murray, Culzean Castle Gardens, third.

Collection of Pears: First, Mr. Alexander Findlay, Uckfield, Sussex, with fairly good fruits. The best were Dr. Jules Guyot, Williams' Bon Chrétien, and Duchess d'Angouleme; second, Mr. James Gibson, Danesfield, Bucks; third, Mr. James Dawes, Ledbury, Hereford.

The chief prize winners in the single dish classes for Pears were Messrs. Alexander Findlay, David Murray, James Dawes, James Gibson, R. R. Greenlaw, Andrew Harvey, William Galloway, John Paterson, John Cairns, R. G. Sinclair, L. M'Lean, Adam Shakelton, A. Hutton, and A. Dickson.

#### PLANTS.

For a group of miscellaneous plants within a circle of 18 feet diameter, Mr. Adam Knight, gardener to Peter Wardie, Esq., Lenzie, was first. His group, which was lightly and tastefully arranged, was composed chiefly of Crotons; interspersed between them were dwarf Caladiums, Ferns, Begonias, Primulas, Dendrobiums, &c. A plant of Acaea leucostachys was in the centre. Mr. G. Wood, gardener to James Buchanan, Esq., Oswald House, Edinburgh, was second, with an exhibit not nearly so attractive.

Four stove plants: First, Mr. John Thorn, gardener to Mrs. Hutchinson, Carlowlie; second, Mr. G. Wood, gardener to James Buchanan, Esq., Oswald House; third, Mr. McKenna, gardener to Sir John Usher, Bart., Ratho.

Two Crotons: First, Mr. Thomas Lunt, with large well-coloured plants; second, Mr. Adam Knight.

Three Fuchsias: First, Mr. William Aitken; second, Mr. A. Atkin.

Two Dracanas: First, Mr. George McKenna, Ratho; second, Mr. Thomas Lunt; third, Mr. John Thorn.

Four exotic Ferns: First, Mr. Robert Stewart, Murrayfield; second, Mr. G. Wood, Oswald House Gardens, Edinburgh.

#### CUT FLOWERS.

Twelve Gladioli: First, Mr. A. Bennett, Tile House, Tweedmouth, with very good flowers; second, Mr. Robert Lawrie, gardener to M. Smith, Esq., Prestwick; third, Mr. Thomas Young, Hartrigge, Jedburgh.

Six Gladioli: First, Mr. A. Bennett; second, Mr. Robert Lawrie; third, Mr. John Prosser, Carstairs.

Twelve show Dahlias: First, Mr. Thomas Robertson, Eastwood, Thornliebank, who showed very well; second, Mr. Robert Sutherland, And Aisle, Kirkintilloch; third, Mr. W. Veitch, The Cemetery, Carlisle.

Twelve Cactus Dahlias: First, Mr. Thomas Robertson; second, Mr. Robert Sutherland; third, Mr. William Government, gardener to Colonel Scott, Wishaw. All showed well, and there were several more exhibitors.

Twelve bunches Sweet Peas: First, Mr. Adam Shakelton, The Grange Gardens, York, with a very good lot; second, Mr. Thomas Duncan, Foggy School House, Duns, whose flowers were good also; third, Mr. Roderick Mackenzie, Strathpey.

Six bunches of Sweet Peas: First, Mr. Adam Shakelton; second, Mr. A. Malcolm, The Elms, Duns.

Twelve Roses: First, Mr. Lawrence Black, Cardenden, Fife, with good blooms; second, Mr. William Parlance, Rosslea Row; third, Mr. Charles Dickson, Corstorphine.

Twelve Tea Roses: First, Mr. Parlance, Rosslea Row; second, Mr. J. D. Bennett, Helensburgh.

Six vases of Roses: First, Mr. Alfred E. Todd, Musselburgh; second, Mr. W. Parlance; third, Mr. David Fraser, Crandon House Gardens.

Twelve bunches hardy herbaceous flowers: First, Mr. Adam Brydon, Tweedbank, Inverleithen, with an excellent lot; second, Mr. A. Dickson, gardener to M. Thorburn, Esq., Inverleithen.

#### NURSERYMEN.

Twenty-four hardy evergreen shrubs: First, Messrs. Cunningham, Fraser and Co., Comely Bank Nurseries, Edinburgh; second, Messrs. James Dickson and Sons, 32, Hanover Street, Edinburgh.

Thirty-six Gladioli: First, Messrs. George Mair and Son, Prestwick, with a splendid display.

Collection of Dahlias: First, Messrs. M. Campbell and Son, High Blantyre, who had a varied exhibit of excellent blooms; second, Mr. Wm. Gold, Durhambank, Wishaw, with smaller blooms.

Eighteen bunches Cactus Dahlias: First, Messrs. M. Campbell and Son, with some beautiful flowers; second, Mr. John Sutherland, Victoria Nursery, Lenzie.

Twenty-four show Dahlias: First, Messrs. M. Campbell and Son, High Blantyre, showing very well; second, Mr. J. Smellie, Pansy Gardens, Busby. Mr. J. Smellie was first for twelve fancy Dahlias; and Messrs. Campbell and Son second.

Twenty-four bunches of Chrysanthemums: First, Messrs. M. Campbell and Son. Twelve vases of Carnations: First, Messrs. M. Campbell and Son; second, Mr. John Forbes. For twelve vases of Picotees, Messrs. Campbell were again first.

#### NURSERYMEN—ROSES.

Thirty-six Roses: First, Mr. Hugh Dickson, Belfast, with some beautiful blooms, notably Mrs. John Laing, Her Majesty, Dr. Andy, Mme. Eugene Verdier, &c.; second, Messrs. D. and W. Croll, Dundee, whose stand also contained some fine flowers; third, Messrs. Alexander Dickson and Sons, Limited, Newtowndale.

Eighteen Roses: First, Messrs. Alexander Dickson and Sons, Limited, with excellent Mildred Grant, Tom Wood, Alexander Dickson and Sons and Sons (seedling), &c.; Messrs. D. and W. Croll, Dundee, were a close second; third, Messrs. W. and R. Ferguson, Brucefield, Dunfermline.

Twelve Roses: First, Messrs. W. and R. Ferguson; second, Mr. Hugh Dickson, Belfast; third, Messrs. Alexander Dickson, Limited, Newtowndale.

Twenty-four Tea Roses: First, Messrs. D. and W. Croll, Dundee, with a nice lot, notably good were Medea, Maman, Cochet, Mme. Lambard, and others; second, Messrs. Adam and Craigmore, Rubishaw, Aberdeen; third, Messrs. Alexander Dicksons, Dunfermline.

Twelve scarlet or crimson First, Messrs. Alexander Dickson and Sons, Limited, with Charles Leefebvre; second, Messrs. D. and W. Croll, Dundee, showing Alfred Colomb; third, Messrs. Ferguson, Dunfermline, with the same.

Twelve Pinks: First, Messrs. Croll, with lovely Mrs. W. J. Grant; second, Mr. Hugh Dickson, Belfast, with excellent Mrs. John Laing; and third, Messrs. Alexander Dickson and Sons, Limited, with the same variety.

Twelve white: First, Messrs. Croll, Dundee; second, Messrs. Alexander Dickson, Newtowndale; third, Messrs. Adam and Craigmore, Aberdeen, all showing Bessie Brown.

Twelve vases of Roses: First, Messrs. Ferguson, Brucefield, Dunfermline, with a pretty display; second, Messrs. D. and W. Croll, Dundee.

Collection of Roses: First, Messrs. James Cocker and Sons, Aberdeen, with a beautiful display; second, Messrs. D. and W. Croll, Dundee; and third, Messrs. Alexander Dickson, Newtowndale.

#### VEGETABLES (OPEN).

Collection of twelve kinds: First, Mr. James Gibson, Danesfield Gardens, Bucks, with a very fine lot. The Onions, Cauliflowers, Tomatoes, Potatoes, and Celery were excellent. Second, Mr. John Waldie, gardener to W. H.

Dobie, Esq., Dollar. His Onions, Turnips, and Celery were fine. Third, Mr. Robert J. Rae, gardener to Major Scott Kerr, Roxburgh.

**Four Cauliflowers:** There were numerous entries. First, Mr. J. Cossar, Spott House Gardens, Dunbar; second, Mr. David Fraser, Crandon House Gardens; third, Mr. R. Stuart, Thirlstane Castle Gardens. Tomatoes were good, the first prize for a dish of twelve going to Mr. R. Grieve, Baerno; second, Mr. Ramsay, Jun., Carlisle; and third, Mr. Robert Watson, Carlisle. Turnips were very well shown, Mr. John Robertson being first for six; Mr. A. Forrest second; and Mr. J. Hood third. Twelve Leeks: First, Mr. John Wood, St. Boswell. **Twelve Onions:** First, Mr. James Gibson, Danesfield, Bucks; second, Mr. Alexander Angus, Dalzell. Twelve varieties of Potatoes: First, Mr. A. Caldwell, jun., Polmont; second, Mr. James Cossar, Spott House Gardens, Dunbar. **Twelve Kidney Potatoes:** First, Mr. A. Caldwell, jun.; second, Mr. Robert Cossar, Inveresk; and third, Mr. James Cossar. **Twelve Round Potatoes:** First, Mr. A. Caldwell, jun.; second, Mr. Robert Cossar; and third, Mr. John Robertson.

#### NON-COMPETITIVE EXHIBITS.

Messrs. Thomas Rivers and Son, Sawbridgeworth, Herts, brought an unique display of fruit trees in pots. The trees were bearing heavy crops of fruit, and had apparently not suffered much from their long journey. Peaches, Plums, Pears, Apples, Figs, and Grapes were represented. Remarkably good were the trees of Peach Grosse Mignonne, Pineapple Nectarine, the Nectarine Peach, Plum Late Orange, Apple Gascoigne's Scarlet, Grapes Gradiska (white), Alicante, and others.

Messrs. R. B. Laird and Sons, Limited, Pinkhill Nurseries, Edinburgh, arranged a group of miscellaneous flowering and foliage plants. The centre consisted of a large Also-pha, surrounded by Hydrangea paniculata, Liliaceae, Phormium, Bamboos, &c. Other mounds of splendidly coloured Crotons, Liliaceae, Dracenas, &c., completed the group. A group of conifers and ornamental shrubs was also exhibited by Messrs. R. B. Laird and Sons. The specimens were very shapely and well grown. Of conifers there were Sciadopitys verticillata, Picea lasiocarpa, Retinospora plumosa aurea, Biota orientalis aurea, Cupressus lawsoniana in good varieties, Juniperus elegantissima, and others.

Messrs. Dobbie and Co., Rothesay, N.B., had a bright and attractive stand of Dahlias, early-flowering Chrysanthemums, Marigolds, Roses, &c. In the centre of the exhibit were stands of Antirrhinums, Marigolds, Chrysanthemums, &c., whilst Dahlias, Roses, &c., were arranged below. The Cactus Dahlias were very beautiful, and represented by splendid flowers; indeed, the same may be said of the other forms of Dahlias.

Messrs. Sutton and Sons, Reading, had a bright and varied miscellaneous display of flowers and vegetables. The group was a circular one, consisting chiefly of tuberous Begonias, Asters, Liliaceae, Lily of the Valley, &c., and bordered by grass, beautifully green, and growing in boxes. Vegetables in variety were interspersed throughout the group.

Messrs. Thomas Methven and Sons, Edinburgh, had a pretty group of Liliaceae, Clematis, Hydrangeas, Caladiums, Crotons, &c. In the centre were tall handsome plants of Acer Negundo variegatum.

Mr. John Forbes, Hawick, N.B., exhibited a bright display of hardy flowers, comprising many beautiful varieties of Phloxes, Pentstemons, Dahlias, Carnations, &c. Quite half the group consisted of Phloxes. The Pentstemons were remarkably fine, and the Dahlia and Carnation flowers in numerous excellent sorts were arranged along the front.

Mr. T. R. Hayes, Keswick, exhibited a collection of hardy Heaths of much interest. There were numerous varieties, included being a new seedling white Heather, Erica vagans var. gracile.

Messrs. Cunningham, Fraser, and Co., Comely Bank Nurseries, Edinburgh, exhibited hardy flowers in variety. The Tritomas were conspicuously fine, and other flowers were Coreopsis, Scabious, Eryngiums, Inulas, Poppies, Pentstemons, &c.

Mr. H. Eckford, Wem, Shropshire, displayed a collection of Sweet Peas in vases in many charming varieties.

Messrs. Laing and Mather, Kelso, exhibited a splendid lot of border Carnations, many beautiful varieties being included. Such a display of Carnations in September is quite unusual. Lady Manners, Crombie's Pink, Uriah Pike, and Sir R. Walde Griffith were just a few of the best.

Mr. John Phillips, Granton Road Nurseries, Edinburgh, had a miscellaneous group of flowering and foliage plants, consisting of Liliaceae, Begonias, Celsias, Palms, Crotons, &c.

Mr. Charles Irvine, Jedburgh, N.B., exhibited a display of Pentstemons, Phloxes, Liliaceae, and other hardy flowers in variety.

Messrs. Lister and Son, Rothesay, N.B., showed a collection of blooms of Pansies, Carnations, and Marigolds.

Messrs. M. Campbell and Son, High Blantyre, N.B., in a group of miscellaneous hardy flowers, showed a splendid lot of Carnations, Dahlias, Phloxes, Asters, &c.

Messrs. James Cocker and Sons, Aberdeen, exhibited a splendid collection of hardy flowers, making quite one of the brightest displays in the show. Tritomas, Gladioli, Gaillardias, Liliaceae, Chrysanthemums, Montbretias, and many more were well represented.

Messrs. D. and W. Buchanan, Forth Vineyards, Kippen, by Stirling, exhibited a collection of Grapes of great merit. There were some splendidly grown bunches of the following varieties: Cooper's Black, Empress of India, Alicante, Queen Victoria, Alnwick Seedling, and Forth Vineyard.

Messrs. Thomson and Sons, Limited, Clovenfords, showed baskets of remarkably fine Grapes, Duke of Buccleuch and Gros Colman, grown with the aid of Thomson's Vine Manure.

Messrs. Storrie and Storrie, Dundee, exhibited some splendid Celsias, tuberous Begonias, Gloxinias, Cocks-combs, &c., as representing the produce of their seeds.

Mr. John Downie, Princes Street, Edinburgh, showed a large group of tuberous Begonias. The plants were well

flowered, and the flowers, which were in great variety of form and colour, were large and boldly displayed.

Messrs. D. and W. Croll, Dundee, showed some splendid Rose blooms in several varieties, and also flowers of a white Phlox.

The Ichthemic Guano Company, Ipswich, filled their usual

position with an exhibit of their specialities, which was tastefully decorated with flowers grown with the aid of Ichthemic Guano. A new speciality, Verda Fertiliser, was noticed.

#### AWARDS.

Gold medals: Messrs. Thomas Rivers and Son and Messrs. R. B. Laird and Sons, Limited.

Silver-gilt medals: Messrs. Sutton and Sons, Thomas Methven and Sons, R. B. Laird and Sons, Limited, Dobbie and Co., Rothesay, and Cocker and Sons, Aberdeenshire.

Large silver medals: Messrs. Laing and Mather, Kelso, D. and W. Buchanan, Forth Vineyards, Kippen, Storrie and Storrie, Dundee, Cunningham, Fraser, and Co., Edinburgh, J. Philips, Granton Road Nurseries, Edinburgh.

Silver medals: Messrs. John Forbes, Hawick, and John Downie, Edinburgh.

Bronze medals: Messrs. Charles Irvine, Jedburgh, A. Lister and Son, Rothesay, M. Campbell, Blantyre, and T. R. Hayes, of Keswick.

Cultural certificates were awarded to Messrs. William Thomson and Sons, Limited, Clovenfords, for Grapes Duke of Buccleuch; D. McLean, Raith Gardens, Kirkcaldy, for a group of Trachelium ceruleum. A silver medal was awarded to Mr. Thomas Lunt, Keir Gardens, Dunblane, for improvement in cultivation of Black Hamburg Grapes in terms of the note with reference to that printed in our schedule. First-class certificates were awarded to Chrysanthemum maximum King Edward, raised by W. Angus, The Gardens, Penicuik, from C. m. Mrs. Head; Rose Duchess of Abercorn, exhibited by Hugh Dickson, Belfast, and raised by him from Maréchal Niel; Carnation Lady Nora Fitzherbert, a very dwarf yellow Carnation, exhibited by Messrs. Laing and Mather, Kelso.

Awards of merit were given to Bronze Violas, exhibited by Messrs. James Grieve and Sons, Redbraes Nurseries, Edinburgh (for strain); three Dahlias, exhibited by Mr. M. Campbell, Blantyre.

#### NATIONAL DAHLIA SOCIETY.

##### NEW VARIETIES.

In continuation of this report, the award of the silver medal presented by Mr. E. Mawley, the President of the National Dahlia Society, for the best bunch of a Cactus Dahlia shown in classes 6 and 7, and another for the best bunch shown in classes 21, 22, 23, and 25, the former was awarded to Messrs. J. Stredwick and Son, St. Leonards, for Miss Florence Stredwick one of three or four very fine, white varieties raised there and exhibited this season; it is a pure white, of the best Cactus shape and character, and highly refined; and the latter to Mr. P. W. Tulloch for Mrs. E. Mawley, a new variety of last year, clear yellow, a very fine and beautiful variety, which promises to be very constant.

The committee of the society sat as a body to make awards of certificates to new varieties of Dahlias, and the regulations of the society required that, in the case of the Cactus varieties in particular, they should be shown without wire supports to show the length of stem; and so they occupied a portion of table by themselves, but not a few of the Cactus varieties, having heavy flowers and weak stems, presented a sorry appearance, hanging down their heads as if doubtful of their charms. It can only be supposed that the flowers were judged as exhibition blooms, as there was no evidence of habit of growth and adaptability for garden decoration. The following received certificates of merit:

*Show Henry Clarke* was the only flower of this type which found favour. It has a pale ground, suffused with lilac on the edges. It was said to have been a sport from T. J. Saltmarsh, which is a yellow self; certainly it was of the same build of flower, and in the case of one bloom some of the petals had a flame or dash of yellow, as suggestive it might at some time assume the fancy character. It was shown by Messrs. Keynes, Williams, and Co., Salisbury.

*Single Snowdrop*.—Ivory white, with a dash of yellow at the base, well-formed flower of good outline and medium size. From Messrs. J. Cheal and Sons, Crawley.

*Pompon Elsa*.—A small, neatly formed, symmetrical pure white flower, a good addition to the white Pompon Dahlias. From Mr. C. Turner, Slough.

*Cactus Eva*.—A charming white variety, with a fairly strong stem; centre good, this being a weak point with some of the new varieties; of the best Cactus shape, a fine acquisition.

*W. F. Balling*.—The ground yellow, the long, incurving florets with a distinct tip of yellow.

*Etna*.—Delicate, soft lilac, slightly shaded; a well-built flower of the best form.

*Eusivius*.—One of the striped varieties raised at St. Leonards, the ground yellow, with pencillings and specks of crimson; fine form, and an excellent companion to the striped Alpha.

*H. J. Jones*.—Yellow ground, the florets delicate salmon and tipped with white, a handsome form of the best character.

The foregoing five Cactus varieties were from Messrs. J. Stredwick and Son, Silverhill, St. Leonards.

*F. A. Wellesley*.—Deep, bright salmon-red, of excellent character, and promising to make a fine exhibition variety. From Mr. H. Shoesmith, Westfield, Woking.

*Tanthe*.—Yellow ground, tinted with salmon and flushed with purple; a flower of considerable refinement. From Messrs. J. Burrell and Co., Cambridge.

*Mabel Needs*.—Bright scarlet; a flower of a rich glow of colour, and finely formed. From Mr. S. Mortimer, Farnham, Surrey.

*Winsome*.—A lovely white variety, perfect in shape and character, the centre all that can be desired; must become a highly popular variety. From Hobbies and Co. (John Green), Dereham.

The committee were by no means unanimous in every case in making these awards, and several others failed to gain the requisite amount of support.

#### LONDON DAHLIA UNION.

ON Tuesday, Wednesday, and Thursday last the above society held an exhibition of Dahlias in the Royal Aquarium. The display was an excellent one, particularly so that made by the non-competitive exhibits. Many of the blooms in the competitive classes were of excellent quality.

#### SHOW AND FANCY DAHLIAS.

Twenty blooms, distinct: First, Mr. J. Walker, Thame, Oxon, who had a splendid stand, Muriel Hobbs, Mrs. Langtry, Ethel Britton, and others being excellent; Mr. Charles Turner, Slough, was second, with very bright and good quality blooms; third, Mr. W. Treseder, Cardiff.

Twelve blooms, distinct: First, Mr. F. W. Seale, Vine Nurseries, Sevenoaks, with lovely flowers; second, Mr. J. R. Traister, Henley-on-Thames,

Twelve blooms, distinct (amateurs): First, Mr. Thomas Hobbs, The Cedars, Downend, Bristol, with good blooms; second, Mr. T. Anstiss, Brigg, Thame; third, Mr. E. Jefferies, Langley Burrell, Chippenham.

Six blooms, distinct: First, Mrs. T. Cooper, Hamlet, Chippenham; second, Mr. T. Anstiss; third, Mr. E. Jefferies, Langley Burrell, Chippenham.

#### CACTUS DAHLIAS.

Twenty-four blooms, distinct: First, Mr. William Treseder, Cardiff, with a very good collection, the flowers of excellent form; second, Messrs. J. Burrell and Co., Howe House Nurseries, Cambridge, who showed well also; third, Messrs. Keynes, Williams and Co., Salisbury; fourth, Mr. Seale, Sevenoaks.

Twelve blooms, distinct: First, Mr. H. A. Needs, Heath View, Horsell, Woking, who had some distinct well-grown blooms; second, Messrs. Keynes, Williams and Co., Salisbury; third, Mr. W. Baxter, Woking.

Twelve varieties in bunches of six blooms: First, Messrs. J. Burrell and Co., Cambridge, with a splendid exhibit, notably of Ida, Albion, Mrs. E. Mawley, yellow; second, Messrs. J. Stredwick and Son, Silverhill Park, St. Leonards, who also had very good blooms; third, Mr. Charles Turner, Slough, with a very bright lot.

Six blooms of one variety: First, Mr. S. Mortimer, Rowledge, Farnham, Surrey, who had splendid blooms of Mrs. Edward Mawley, yellow; second, Messrs. Keynes, Williams and Co.; third, Messrs. J. Stredwick and Son, Silverhill Park, St. Leonards.

Three vases, each containing nine blooms each: First, Mr. F. W. Seale, Vine Nurseries, Sevenoaks; second, Mr. H. A. Needs, Horsell, Woking; third, Messrs. Keynes, Williams and Co., Salisbury. The arrangement of the foliage in this class was not of the best.

Three vases of Cactus Dahlias (prizes given by Messrs. F. W. Sharp, Twyford, and R. Dean): First, Mr. F. W. Seale, Vine Nurseries, Sevenoaks; second, Messrs. Keynes, Williams and Co., Salisbury; third, Mr. J. Walker, Thame, Oxon.

#### AMATEURS.

Six blooms, distinct, special prizes by Hobbies, Limited: First, Mr. H. A. Needs, Horsell, Woking, with some good blooms, particularly that of Mrs. H. J. Jones; second, Mr. E. Mawley, Rosebank, Berkhamsted; third, Mr. E. West, Jun., Frieth, Henley.

Twelve blooms, distinct: First, Mr. H. A. Needs, Horsell, Woking, with very good blooms; second, Mr. E. West, Jun., Frieth, Henley; third, Mr. W. Peters, Baldslow, St. Leonards.

One vase of twelve Cactus blooms: First, Mr. P. W. Tulloch, New Church Road, Hove, who showed a bold exhibit of yellow blooms; second, Mr. H. A. Needs; third, Mr. A. Taylor, 5, Vernon Terrace, East Finchley.

Nine varieties in bunches: First, Mr. P. W. Tulloch, Hove, who showed splendidly; a good second, Mr. Herbert Erousson, Jun., Sidcup; third, Mr. W. Peters, St. Leonards.

Six varieties: First, Mr. L. McKenna, Honey, Waltham St. Lawrence, Berks, whose blooms were of excellent form and bright; second, Mr. E. Mawley, Berkhamsted; third, Mr. W. Peters, Holmhurst Lodge, St. Leonards.

#### POMPON DAHLIAS.

Twelve varieties: First, Mr. Charles Turner, Slough, who exhibited a delightful stand of charming sorts; second, Messrs. J. Burrell and Co., Cambridge; third, Mr. F. W. Seale, Sevenoaks; fourth, Mr. J. Walker, Thame, Oxon.

Six varieties (amateurs): First, Mr. W. C. Pagram, The Whim Gardens, Weybridge; second, Mr. T. Cooper, Hamlet, Chippenham; third, Mr. W. Peters, Baldslow, St. Leonards.

#### SINGLE DAHLIAS.

Twelve varieties, in bunches: First, Mr. F. W. Seale, Vine Nurseries, Sevenoaks, with a delightful exhibit, Huntsman, Columbine, Edie, Oblein, &c., being very pretty; second, Mr. J. Walker, Thame, Oxon; third, Mr. C. Osman, District Schools, Sutton.

Six varieties, in bunches (amateurs): First, Mr. E. Mawley, Berkhamsted; second, Rev. S. Spencer Pearce, Combe Vicarage, Woodstock; third, Mr. C. Osman, Sutton, Surrey.

#### NON-COMPETITIVE EXHIBITS.

There were many beautiful displays of Dahlias and miscellaneous flowers made by various nurserymen, and awards were given to them as follow:

Gold medals.—Messrs. H. Cannell and Sons, Swanley, Kent; Messrs. J. Burrell and Co., Howe House Nurseries, Cambridge; and Hobbies, Limited, Dereham.

Silver-gilt medals.—Messrs. Dobbie and Co., Rothesay, N.B.; Mr. J. T. West, Tower Hill, Brentwood; Messrs. Isaac House and Son, Westbury-on-Trym, Bristol; Messrs. Blackmore and Langdon, Twerton Nurseries, Bath; and to Hobbies, Limited, for Roses.

Silver medals.—Mr. J. Walker, Thame, Oxon; Messrs. W. H. Cutbush and Son, Highgate, N.; Messrs. T. S. Ware, Limited, Feltham; and Mr. Eric Such, Maidenhead.

Certificates of merit were awarded to the following:-

CACTUS VARIETIES.

From Mr. William Treseder, Cardiff.—Charm and Minnie West.

From Messrs. J. Stredwick and Son, St. Leonards.—Eva, Vesuvius, H. J. Jones, and Ethna.

From Hobbies, Limited, Dereham.—Red Cap and Winsome.

From Messrs. Keynes, Williams and Co., Salisbury.—Mrs. T. Cherry and Prince of Orange.

From Messrs. J. Burnell and Co., Cambridge.—Enchantment and Albion.

From Mr. S. Mortimer, Farnham.—Manxman.

SHOW DAHLIAS.

From Mr. William Treseder.—Mrs. W. Treseder.

From Messrs. Keynes, Williams and Co.—Gold Mantle and Henry Clarke.

From Mr. St. Pierre Harris.—A. M. Burnie.

EAST ANGLIAN HORTICULTURAL CLUB.

This progressive club had a largely attended September meeting, Mr. J. Powley was in the chair, Mr. T. E. Field occupying the vice-chair. The exhibition tables were taxed to the utmost with flowers, fruits, and vegetables in the monthly competitions, and some creditable specimens were to be seen amongst them. The cup presented by Mr. C. W. Daws was secured by Mr. C. H. Hines, gardener to Garrett Taylor, Esq., Trowes, with the largest number of points in the aggregate of three competitions, whilst Mr. E. C. Ramus, Hetherset, secured the silver bowl presented by E. T. Boardman, Esq., Town Close, Norwich, for three monthly competitions.

In the non-competitive exhibition Mr. G. Daniels had a pretty arrangement of a new single Dahlia raised by himself. The variety has a deep incision in the centre of each petal, giving it a unique appearance; the floral committee gave it a first-class certificate. Mr. G. Davison had another seedling perennial Phlox of good merit, named Westwick Scarlet, with brilliant-hued flowers. This also received a first-class certificate. Mr. Davison had also a bunch of the new *Helianthus mollis* and *Montbretias* in profusion, including some blooms of Germania. During the evening two essays were read, the first by Mr. H. B. Dobbie upon "The Fertilisation of Flowers," and the other by Mr. E. Yeomans upon "My Experience with the Cultivation of the Mushroom." Mr. Dobbie dealt with his subject in a very able manner, his botanical knowledge serving him in good stead, his explanation of the work of the stamens, pollen, stigma, and ovary were keenly followed. A capital discussion followed at the close of each paper.

BIRKENHEAD.

THE horticultural show held in conjunction with the Wirral and Birkenhead agricultural exhibition on the 10th and 11th inst., was held in the new grounds at Bebington, which cover 22 acres, and have cost, with the building, £23,000. Undoubtedly when completed this will prove one of the best show grounds in the country. The position allotted to horticulture is not at all suitable, the permanent felt roof being far too dark to allow of the beauties of foliage and flower to be seen. The entries were very satisfactory, numbering 1,100, or double those at the last exhibition. The exhibits generally were below the average, vegetables excepted; these were both strong in number and good in quality.

PLANTS.

For the group arranged for effect, not to exceed 60 square feet, Mr. H. Ogden, West Derby, was a good first, Palms and Crotons occupying the apices of small mounds composed of good Ferns, Geraniums, Begonias, *Francoa ramosa*, &c. Mr. S. Haines, gardener to E. K. Laird, Esq., Birkenhead, was a good second.

Ten stove and greenhouse plants: The same exhibitor was first, his best plants being Croton and *Alocasia*. Three stove and greenhouse plants in flower: First, Mr. H. Ogden; second, Mr. J. Bryan, gardener to E. F. Peel, Esq. Three foliage plants: Mr. Haines had again the best, followed by Mr. G. M. Steeves. One Palm: The first and second were Mr. L. Cookson and Mr. S. Haines.

In connexion with the various exhibits it is to be regretted that the committee do not enforce the regulation that all must be named.

CUT FLOWERS.

These were in great quantity, and proved highly interesting. Six Roses: Mr. S. Bell won with good blooms, and Mr. J. Davis for three blooms.

Twelve Cactus Dahlias: Mr. H. Banks led with good blooms, holding a similar position for six varieties.

Twelve Dahlias other than Cactus: First, Mr. H. Banks. Mr. John Clarke won for six varieties.

For a stand suitable for table decoration, John Ennion, Esq., won in a good competition. C. J. Procter, Esq., secured the chief awards for hand bouquet, bouquet of hardy flowers and for three ladies' sprays.

The class for twelve bunches of flowers grown in the open brought a grand display, Mr. J. Lee coming out at the top. J. Ennion, Esq., held a similar position for six bunches.

FRUIT.

Mr. O. Roberts, Tarporley, had the best collection, consisting of white and black Grapes, Peaches, Figs, Nectarines, Melons, and Apricots; Mr. C. Jones was second.

Six kinds of hardy fruits, not more than six of any kind on each dish: In this class were four disqualifications, many staging upwards of fifty Cherries, fifty bunches of Currants, &c. The wording of this should be altered, as six fruits of Gooseberries, for instance, which one exhibitor staged, form too meagre a lot. A. J. Oakshott, Esq., had the best.

Mr. E. Stokes had the best Black Hamburgh Grapes, and Mr. O. Roberts for any other black won with Black Alicante. For two Muscats, Mr. W. Gaunt, gardener to P. Walker, Esq., was first; and Mr. T. Ferguson, gardener to Mrs.

Paterson, won for any other white, with richly-coloured the Buckland Sweetwater. Mr. H. May, gardener to C. Gatehouse, Esq., had the best Peaches, and Mr. O. Roberts the best Nectarines. Mr. T. B. Kendall had the leading scarlet flesh Melon, and Mr. E. A. Young the green flesh.

Vegetables were altogether a fine lot; unfortunately, the tent was much too small, the result being that half the exhibits were on the floor and many under the stage. In the classes for collections the wording is such that it results in much extra labour being given to the judges, by stating that "not less" than a certain number be staged, a distinct number would be better both for the exhibitor and the judges.

Collection of vegetables, not less than eight kinds: First, Mr. Edward Alty, Ormskirk, with fine Cauliflowers, Potatoes, Onions, Leeks, &c.; Mr. W. Mackerall was second. For not less than six kinds, Mr. Henry Jones was the winner.

Mr. W. Millington, Bronborough, had the best dozen Tomatoes. Mr. J. P. Platt the best six, and Mr. Stanley Clark won for six yellows, a fine lot of fruit throughout.

Mr. J. Taylor, Malpas, had the best twelve white round Potatoes. Mr. J. Bradshaw, Higher Bebington, the best twelve coloured. Mr. J. Davis, Leominster, was first for white Kidneys; and Mr. J. R. Carter, Chester, had the best twelve coloured Kidneys.

NON-COMPETITIVE EXHIBITS.

Mr. J. Webster, Wavertree, secured the society's silver medal for an exhibit of a tenant's greenhouse, showing also a capital addition for a villa residence, boilers, &c. Messrs. Dicksons, Chester, exhibited herbaceous cut flowers, Palms, &c.; Mr. H. Middlehurst, Liverpool, Sweet Peas, vegetables; and Mr. W. H. Shilton, West Derby, greenhouses and frames; Mr. Mason showed a tenant's greenhouse, &c.; Mr. McHattie, Chester, cut Gladioli; Mr. G. Smith, Birkenhead, border flowers, Dahlias, &c.; Mr. W. Rowlands, West Derby, Cactus Dahlias, &c.; Mr. G. Jones, Birkenhead, conifers, Clematis, &c.; and Mr. H. Eckford, Wem, Cactus Dahlias, Verbenas, &c. Mr. A. H. Edwardson, secretary, supervised the whole exhibition.

NATIONAL AMATEUR GARDENERS' ASSOCIATION.

THE monthly meeting took place at Winchester House, Old Broad Street, E.C., on Tuesday, the 2nd inst., at seven o'clock in the evening. The chair was taken by Mr. Eland G. Sinclair, who, after the usual business had been got through, called upon Mr. T. W. Sanders, F.L.S., the president of the association, to give his lecture, entitled "How Plants Grow and Feed." The lecture was exceedingly interesting, and made especially so by the series of diagrams, which were enlarged by the aid of good lantern. The lecturer has given considerable attention to the subject of his discourse, and in consequence a profitable evening was spent by the members present on this occasion. A splendid show was arranged in the great hall of Winchester House. In the vegetable department the chief contest was for the Carter trophy, value £10 10s. There were only two competitors, but the quality of their produce was exceptionally good. The competition was for six varieties of vegetables, distinct. Half a point divided the two displays, the leading exhibit coming from Mr. George Hobday, Romford, Essex, his Cauliflowers, Potatoes, Peas, and Carrots being of great merit, the display, as a whole, being set up in splendid style. Mr. F. M. Vokes, Southampton, was an uncomfortably close second, his Peas, Tomatoes, and Onions being very good. Grapes, Apples, Pears, and Plums were freely shown, which goes to prove the comprehensive character of the contents of the members' gardens. Flowers are always well shown, and the subjects staged on this occasion embraced a charming variety. Six competitors set up collections of six bunches of hardy flowers, distinct, and charming were their displays. Mr. D. B. Crane secured leading honours, with large and handsome bunches pleasingly arranged. Mr. F. M. Vokes, Southampton, was placed second with smaller bunches of beautiful subjects. Dahlias in variety, annuals, Gladioli, besides many flowers grown under glass, were freely displayed. There were several competitions in which the winner of the highest aggregate in number of points is determined at stated periods of the year, and these classes were unusually interesting. On October 7 next Mr. S. Hillman will give a lecture on "The Lily Family." The secretary is Mr. F. Finch, 117, Embleton Road, Lewisham, London, S.E.

## ANSWERS TO CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

**Names of plants.**—*W. L. B.*—Cotoneaster frigidus. —Miss O.G.—Please name enclosed flower. It comes from a place thirty or forty miles south of Tangiers and has been flowered in a pot. It is thought to be a kind of Narcissus from bulb and manner of growth. The finder and owner

knows of a much bigger kind quite close to Tangiers with the same peculiar odour. He has several pots of these small bulbs, and all are flowering now and very pretty.—[The Narcissus is *N. serotinus*.]

**Names of fruit.**—*Goodfellow.*—1, King Harry; 2, Golden Spire.—*W. H. G.*—1, Cox's Orange Pippin; 2, Cox's Pomona; 3, Fearns Pippin; 4, Crimson Costard; 5, Cornish Gilliflower; 6, Beurre Clairgeau.—*C. L. Adams.*—1, Stubbard; 2 and 9, Keswick Codlin; 4, Keswick Codlin Improved; 3, Pearson's Plate; 5, Pear Bergamotte d'Esperie; 6, Lord Sutherland; 7, Nelson's Codlin; 8, Hambleton d'Ans; 10, Pear Beurre Bosc.—[We shall be very pleased to name any fruits sent to us during the coming fruit season.]

**Galls on Metrosideros** (H. D. PALMER).—The growths on the stem of your Metrosideros speciosa are not galls of any kind but young flower buds, which apparently are more or less abortive.—G. S. S.

**Peter's Wreath.**—In THE GARDEN of August 16 M. P. Forster asks for the botanical name of Peter's Wreath. I believe it is *Petrea volubilis*, and I am supported in this by Bailey's "Cyclopedia of American Horticulture," to which I have just referred.—A. HERRINGTON, Madison, N.J., U.S.A.

**Lilium candidum not succeeding** (FRANCES).—The malformation of the flowers is probably due to insufficient ripening of the bulbs or from their being grown in too rich soil. The addition of sand to the soil might be beneficial. A variety called *monstrorum* is in cultivation, with flowers similar to the one sent. Your plants may be affected by this variety; if so it is doubtful whether the flowers can be altered.

**Violet plants collapsing** (W. H. G.).—The well-grown specimen of Violet plant sent for our inspection has been suffering from an attack of red spider, which quickly reduces the health and strength of the plants, and if not destroyed soon renders them of no value. The cause of collapse, however, in this case is a clean puncture cut through the root-stem of the plant, and is clearly the work of wire-worm or some other destructive pest. We would advise our correspondent to lose no time in taking up his plants and placing them in their winter quarters for flowering; the roots may then be examined and the enemy, if found, destroyed.

**Iris with Myosotis** (A. M. S.).—To a certain degree this depends on the age and condition of the latter plant, which, if established, commences its flowering towards the end of May. It is, however, not in its best condition for some fortnight longer, and then a large array of the Flag Irises are in flower. What you should avoid chiefly would be those nearest to typical germanica, all of these being early in bloom. Any of the squamata, variegata, or aphylla sections would do quite well, and of these we give a selection: Pallida, Pallida dalmatica, and Imogene are nearly 3 feet high, shades of the most exquisite sky and pale blue, quite indispensable; Mrs. H. Darwin and L'Innocence are the best whites; Dr. Bernice and Arnolda are bronzy copper and dark shades; aurea, Chelles, and Abbot Hasson are gold and crimson; Flavescens, Darius, Gracchus, and Ganymede are paler yellow shades with crimson markings on the lower petals; Mme. Chereau is white with violet pencillings; Walmer is a good azure blue; and Queen of May and Telegraph are very beautiful in warm tints of lilac-rose. Indeed, the above contain some of the very cream of the Flag Irises, than which in the month of June there are no more beautiful flowers.

QUESTION.

**Bulbs and field mice.**—Can you suggest anything to prevent Bulbs being eaten by field mice? We are close to a wood, and though there are owls in plenty yet the mice hold their own. Would dressing with red lead or paraffin have any ill effects on bulbs, Crinum, Hyacinth, Tulip, &c., or can you suggest a remedy?—GOODFELLOW. [Would some reader who has had similar experience help our correspondent.—ED.]

CATALOGUES RECEIVED.

**Bulbs.**—Messrs. Daniels Brothers, Limited, Norwich; James Cocker and Sons, 130, Union Street, Aberdeen; H. Cannell and Sons, Swanley, Kent; Edmondson Brothers, 10, Dame Street, Dublin; Barr and Sons, Covent Garden, London; John Russell, Richmond, Surrey; Robert Pringle, 40, Belvoir Street, Leicester; William Bull and Sons, King's Road, Chelsea; Dicksons, Chester; James Carter and Co., High Holborn, London; William Sampson and Co., Kilmarock; W. Smith and Son, Aberdeen; Ant Rozen and Sons, Overeen, near Haarlem, Holland; Pope and Son, King's Norton, Birmingham.

**Plants.**—East Anglian Plant Company, Great Totham, Witham, Essex; Carl Sprenger, Vomero, Naples, Italy.

**Trees and Shrubs.**—Muskauer Baumschulen, Muskau, Lausitz.

## OBITUARY.

### M. CHARLES JOLY.

M. JOLY, the honorary vice-president of the National Horticultural Society of France, died, we regret to learn, on August 25, at the age of eighty-four years. M. Joly had invented a system of heating which he patented, and which is now in use. M. Joly had received the Cross of the Legion of Honour for his services. His death deprives the society of an eminent and devoted member, who had rendered valuable help during many years.

[SEPTEMBER 27, 1902.

## SCHOOL GARDENS IN GERMANY.

THE Board of Education has lately issued a reprint of a special report on certain German school gardens visited last year by Mr. T. G. Rooper, one of His Majesty's Inspectors of Schools, which furnishes much food for thought, and we would gladly direct the attention of our readers to this suggestive pamphlet.

For nearly a century past Germany has been alive to the supreme importance of training the children of agricultural districts in the intelligent cultivation of the land, and has been advancing year by year towards the attainment of this momentous end. We have some account in these fifty odd pages of interesting details of the garden schools of various grades which are established, at no wide intervals, up and down the entire length and breadth of the country. We are told of the opportunities offered at well-equipped horticultural centres to landowners who can attend within easy distance of their homes courses of instruction in forestry, vine culture and fruit growing, landscape gardening and horticulture, no less than to elementary teachers, farmers, and professional gardeners, the latter classes being assisted by Government grants for expenses and fees when they are unable themselves to defray the cost of such practical education. We also learn that a large proportion of elementary village schools are provided with garden ground where the elder children are trained in the grafting and management of fruit trees, of vegetables, and of flowers—not omitted—as are best suited to the conditions of the particular district. Even town schools, it would seem, are not left out of the general scheme, and have their allotted garden plots. The whole treatise, in fact, goes to prove the old adage that "an ounce of practice is worth a pound of theory." Book work—valuable as it is and dear to the heart of the schoolmaster—is barren and unproductive while divorced from the labour of the hands. We gather that in Germany, as in England, the trend of public feeling, especially amongst working people, is to lower the dignity of labour; for the difficulty there, in spite of all the advantages offered by Government, is to find good practical teachers. Hence the school garden itself has tended in many instances to "become a means of illustrating botanical studies rather than

gardening." But wherever a clever and enthusiastic practical teacher has been established in any given district—as in the admirable elementary school at Geistingen, in the valley of the Sieg, and in the Westphalian village of Celsberg on the Ruhr—the great benefit of systematic garden training is clearly to be traced in the improved comfort and prosperity of the inhabitants of the locality.

A significant fact is worth noting, that those districts are most advanced and prosperous where some influential landowner, not necessarily connected in any way with school management, has been found to take a personal interest in the matter, a case in point being the mayor of a town in the neighbourhood of Geistingen, who began the work of reformation in fruit growing in his own vicinity by himself planting, as a beginning, some 4,000 fruit trees of good sorts after approved methods.

It is not now for the first time in the pages of THE GARDEN that foreign methods of instruction in fruit growing and general tillage of the land have been put before our readers. The British nation is being aroused to the fact that—from the wealthy owner of vast estates to the poor dweller in the humblest cot—the subject, educationally, is one of utmost urgency, far-reaching as to the limits of the great Empire to which we belong, yet touching closely the well-being of every cottager. May the time soon arrive when we may all be thoroughly wide awake to it and doing, each what in us lies, to help forward both by knowledge and practice the "Art which nourishes all other Arts."

## KEW NOTES.

### INTERESTING PLANTS IN FLOWER.

#### Temperate House.

BERLANDIERA TOMENTOSA, Crowea saligna, Dianthus arboreus, Lilium nepaleuse, Passiflora capsularis, and Salvia splendens var. grandiflora.

#### Palm House.

Clerodendron disparifolium, Crinum Kirkii, Hymenocallis eucharidifolia, Medinilla venosa, and Passiflora kewensis.

#### T Range.

Eschynanthus lobbiana, Amazonia calycina, Aphelandra chamissoniana, Begonias in variety, Cereopsis Woodii, Hemianthus Clarkei, H. coccineus, H. tigrinus, Passiflora amabilis, and Pavetta hispidula.

#### Orchid Houses.

Angraecum eichlerianum, Anguloa Ruckeri, Catasetum uncatum, Cynorkis purpurascens, Dendrobium chrysanthum, D. crumenatum,

Epidendrum ciliare, E. inversum, E. prismatocarpum, Laelia elegans, Lycaste xylophora, Maxillaria nigrescens, Miltonia Clowesii, M. Regnelli, Odontoglossum andersonianum, O. grande, Oncidium varicosum, Stanhopea oculata, and Stenoglottis longifolia.

#### Greenhouse.

Abutilons in variety, Begonias in variety, Campanula isophylla var. Mayi, C. Loreyi, Cannas, Celosia pyramidalis, Hidalgoa Wercklei, Lilium speciosum and varieties, Primula obconica, &c.

#### Rock Garden.

Corydalis thalictrifolia, Lobelia syphilitica, Enothera missouriensis, and Polygala chama-buxus.

#### Herbaceous Plants.

Argemone grandiflora, Aster in variety, Boltonia indica, Chelone Lyoni, Colchicum autumnale, C. byzantinum, C. latum, C. Sibthorpii, C. Szovitsii, C. Tenorei, C. variegatum, Dicentra formosa, Digitalis ambigua, Eupatorium purpureum, E. serotinum, Gerbera Jamesoni (last week this plant inadvertently appeared as G. punicea), Lobelia Erinus, L. Tupa, Mesembryanthemum pyropaeum, Scutellaria haicalensis, Silene Fortunei, Stevia Eupatoria, Sunflowers in variety, and Zizania aquatica.

#### Shrubs.

Aralia spinosa, Clematis apiifolia, C. campaniflora, C. connata, C. grata, C. orientalis, Erica ciliaris, E. multiflora, E. vagans, Hamamelis virginica, Hypericum aureum, H. hircinum, H. proliferum, Kadsura chinensis, Ligustrum lucidum, and L. Quihoui.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

October 7.—Royal Horticultural Society, meeting of committees, Drill Hall, Westminster; National Chrysanthemum Society's Show, Royal Aquarium (three days); National Chrysanthemum Society, meeting of Floral Committee; meeting of Scottish Horticultural Association.

October 20.—Meetings of National Chrysanthemum Society's Floral and Executive Committees.

October 21.—Royal Horticultural Society, meeting of committees, Drill Hall, Westminster.

October 28.—Croydon Chrysanthemum Show (two days).

October 29.—Kent County Chrysanthemum Show at Lewisham (two days); Highgate Chrysanthemum Show (three days).

October 30.—Penarth Chrysanthemum Show.

October 31.—Finchley and Leyton Chrysanthemum Shows (each two days).

**Roses at North Mymms.**—Several houses at North Mymms Park are devoted to the culture of choice Tea and Hybrid Tea Roses on what is there termed the American system. None are in pots, all are planted out. Most of the plants have been raised from cuttings. Nice firm pieces of wood cut off and inserted in heat in midwinter give a wealth of plants for putting out in the summer, and of course all on their own roots. There is in each house a very large flat or terraced bed on iron stands. The floors are of wood trellis and the sides of inch boards 10 inches deep. On the trellis chopped turf is

placed, the space within the sides being filled with good turf loam and well-decayed manure, into which the Roses are planted. The side beds are similar, but some 3 feet wide only. Up to the beginning of winter flower-buds are kept pinched out. This induces the formation of secondary shoots in greater number, and these produce the flowers in the winter in great profusion.—A. D.

**Winter Carnation America.**—There is a very large and superbly grown stock of this yet comparatively little known winter Carnation at North Myrmans Park, Hatfield. It is a robust grower, yet not of elongated habit, makes a fine pot plant, and flowers freely. The flowers are much larger than are those of Winter Cheer, are of much the same deep scarlet hue, and, not least of its merits, are deliciously perfumed. Mr. Fielder saw it some two or three years since, and realising its great excellence purchased plants, so that now he has hundreds of strong ones. Very likely all being well he will exhibit a group of the Carnation at the Drill Hall in the winter. If so there can be no doubt but that it will be greatly admired. To have a Carnation of such rich perfume and of such deep colour in midwinter is indeed a prize.—A. D.

**Carnation George Maquay.**—Will you kindly let me add to my note about the Carnation George Maquay last week that it should be spelt without the "c." It seems to me an error on the part of raisers of Carnations not to raise hardy, vigorous, continuous bloomers. What does it matter about the shape of the flower if the plant goes out of bloom in ten days, as many varieties do in hot seasons in the south?—W. R.

**Three good new dwarf bedding Lobelias.**—I have this summer grown for trial and comparison in my garden, where I use them as edging to some of my beds, three new varieties of the *Eruca* section of this free blooming and ornamental family, named respectively Mrs. Clibran, sent out last year by the well-known firm at Altringham, whose name it bears; Newport's Model, sent out this spring, which was well shown and greatly admired at this year's great Temple show; and Chapman's King Edward, raised by Mr. Chapman, of Grangemouth, N.B., first shown and awarded a certificate of merit at the Royal Horticultural Society's great show at Holland House on June 25. Of these varieties I consider the second-named decidedly the best and most beautiful, as it has a fine large white eye, surrounded by a border of the deepest purple, and was greatly admired by all visitors to my garden. The first-named has a smaller white eye, but is very free blooming, and remains perhaps rather longer in flower than Newport's Model. The third variety, King Edward, came too late in the season to enable me to form an adequate or accurate opinion of its relative merits as compared with the other two kinds, as each of my six plants only produced two or three flowers, which have a fine large and pure white eye, surrounded by a rather narrower border of rich deep purple. I hope to see this variety to greater advantage next summer, but from what I have seen of it so far I think it will be entitled to take second place among the three. Its habit of growth leaves nothing to be desired, being most compact and dwarf. I have also grown as a back line in two of my annual borders a much taller-growing variety of *Lobelia*, sent to me under the name of *L. racemosa*, which grows about a foot high and has relatively large flowers, which vary somewhat in shade, some being of the deepest blue, while others are somewhat paler. The flowers of this variety also have the peculiarity of half closing every evening.—W. E. GUMBLETON, Ballygore, Queenstown, Ireland.

**Blue Hydrangeas.**—Just what causes *Hydrangea Hortensia* to produce blue flowers when set out as a shrub is still a moot question. There are hundreds of them growing outdoors permanently in Philadelphia and vicinity, and when in sheltered places and in seasons following a mild winter, when the wood is not badly hurt, they flower fairly well, and the blooms are practically always blue. Just why it is that the planting out makes this change seems inexplicable. The plant may be in the same kind of soil, grown in a

tub, and set out on a lawn, but there is no surety of blue flowers. On the contrary, almost always they are of the normal pink colour. Nurserymen are continually being asked for blue *Hydrangeas*, and when the common *H. Hortensia* is offered with proper explanation the surprise is very great. During the summer just closing the display of blue flowers on the planted out *Hydrangeas* has been uncommonly fine. I am told it has been the same at Newport, R.I. Can any of our readers say?—JOSEPH MEERAN, in *The Florist's Exchange*.

**A new Hydrangea.**—The new *Hydrangea superba* was honoured with a silver-gilt medal at the Massachusetts Horticultural Society's exhibition in Boston on July 27 last. It is a seedling raised by M. H. Walsh, of Wood's Holl, who gives the parentage as *H. Otaksa* and *H. cyanoclada hortensis*, the plant illustrated being now four years old. The flowers at the time of exhibition presented a beautiful gradation of pink, violet, and blue, the youngest blooms being white. The flowers are of great substance and borne on slender wiry stems.—*The American Florist*.

**Apple Cornish Aromatic.**—This variety is not so well known as it deserves to be. The fruit develops to a large size under good conditions, and is very handsome and showy, in some instances being mistaken for a Peach when grown on a wall owing to its fine colour. The flesh is firm and juicy, aromatic, and of good flavour. It is best in a sheltered position, and does well in gardens as a bush or horizontally trained or fan-shaped on a wall, the latter method being adopted by Mr. C. Beckett, of Chilton Lodge, who grows this variety on a west aspect to perfection. It is surprising that some of our large fruit nurserymen do not catalogue this fine sort. It must not be confounded with Cornish Gilliflower, a variety with delicious flavour but a bad grower.—J. G., Cam.

**Notes from the Royal Horticultural Society's Fruit Show.**—Mr. Berwick, Sidmouth Nurseries, Devon, is to be congratulated upon his success in obtaining the highest award (a gold medal) for a display of fruit grown entirely out of doors, arranged upon a table 48 feet by 6 feet. Mr. Berwick has competed for the gold medal for many years, but has never until this year been able to gain more than second prize. His exhibit, although not up to the standard attained by other first prize winners in more favourable years, was, considering the extremely trying season, one of great merit. Mr. George Woodward's exhibit from Barham Court Gardens, Maidstone, was of a very different nature to that usually sent by him to the Crystal Palace Fruit Show. Mr. Woodward is invariably one of the most successful exhibitors of hardy fruit at this show, but owing to the hailstorm of unprecedented severity which visited Barham Court Gardens a fortnight or so ago the fruit crop was practically wrecked. Samples of the damaged fruits were sent last week to the fruit show, and they were terribly disfigured and mutilated by the hail. Shoots of Apple trees and Chrysanthemums, completely stripped of their leaves by the storm, were also shown. Mr. Woodward gave the following information concerning the damage done:—"By the hailstorm on the 10th inst., 6,000 Peaches, several hundred bushels of Apples, Pears, Plums, and Damsons were totally destroyed: the trees were very much damaged, and some irretrievably ruined. Vegetables, too, were in shreds and useless. On the 17th inst., solid blocks of hail 4 feet thick and 50 yards long could be seen."—A. P. H.

**Early-flowering Chrysanthemum Horace Martin.**—This latest addition to what is generally known as the Mme. Marie Masse family of early-flowering Chrysanthemums is undoubtedly the best of the several sports. A high opinion was formed of its merits last season when it was submitted to the respective floral committees of the National Chrysanthemum Society and the Royal Horticultural Society. The first-mentioned society awarded this variety a first-class certificate, and the latter society placed their award of merit to its credit. The form of the flowers is dainty and pleasing; they are

developed in wondrous profusion, and the capital length of footstalk, which is an excellent trait in the character of all flowers of this family of Chrysanthemums, gives them a value, when grown without disbudding, which very few of the early sorts possess. The colour at this season may be described as a rich canary yellow, deepening in the centre of the bloom. Most of the plants are 3 feet through and are literally covered with blossom. Contrasted with a group of Crimson Marie Masse, from which it is a sport, the effect is very striking and handsome. The robust character of the plant's constitution, together with its vigorous growth, go to prove that another season will see this beautiful variety distributed freely throughout the country. Plants of this description when judiciously grouped in the hardy border do much to brighten and enrich their surroundings in the autumn months.

**Chrysanthemum Norbert Puvrez.**—This is an early-flowering Chrysanthemum, introduced some ten or twelve years ago, and of which little has been heard since. Recently at a lecture on early-flowering Chrysanthemums at Kidderminster, Mr. William Sydenham sent with others, for the purpose of illustration, a charming bunch of this variety. The bunch was very much admired by all who saw it, and the variety may be included in the list of really good things for outdoor displays. The bunch of blossoms had been cut from the open ground, and appeared to be little the worse for the unpleasant weather of late. The colour is a deep rich golden-salmon, and the flowers are of good size, height about 18 inches to 2 feet, the period of blossoming is September and later as weather permits.—D. B. C.

**Gardenia Thunbergia.**—A specimen of this old but rarely seen shrub has for several weeks past been flowering well in the Mexican house at Kew. It has been cultivated off and on at Kew for more than a century, and was introduced to Kew by Sir James Cockburn, Bart., about 1773. In 1807 it was figured in the *Botanical Magazine*, t. 1004, the specimen being obtained from Mr. Greville's garden at Paddington. It is said to be widely distributed through Central and Southern Africa, large specimens also being found on the Gold Coast. The largest specimen at Kew is about 7 feet high, and is of dense habit. The leaves are evergreen, more or less oval and acute, and are often arranged in whorls. The largest are from 5 inches to 6 inches long and 2 inches to  $\frac{1}{2}$  inches wide. The white flowers are borne singly from the ends of the growths. As in the case of the well-known double *Gardenia*, the flowers are extremely fragrant, but differ considerably in shape. In the case under notice the flowers have slender tubes 4 inches to 6 inches long, the limbs of the corolla having a diameter of 3 inches or so. It appears to be a difficult plant to flower when young, though it is by no means so to grow. At Kew it is planted out in a border of loam in an intermediate temperature.—W. DALLIMORE.

**Eustoma russellianum.**—Owing to the difficulty experienced in growing this plant it is rarely seen in gardens, though when it does happen to flower it is highly ornamental. In the Mexican house at Kew a few plants are now in flower, where their distinct appearance makes them conspicuous among surrounding plants. It is a native of Mexico and Texas, and was introduced nearly a century ago. It is really a biennial, though it has sometimes been grown as an annual. It grows about 1 foot or  $1\frac{1}{2}$  feet high, and produces ovate leaves and terminal corymbs of light purple flowers, each flower being 3 inches across. Some years ago it was grown well in the nurseries of Messrs. Dicksons of Chester. The seeds in that case were sown in a pan of finely-sifted soil, which was placed in a tropical propagating house. The young plants were grown on a shelf near the glass in the same temperature until they were several months old, when they were placed in a warm but airy greenhouse, where they flowered. The plants at present flowering at Kew were grown in an intermediate temperature throughout. In some places this plant is much better known under the name of *Lisianthus russellianus*, which is a synonym of *Eustoma russellianum*.—D.

**Cuphea platycentra.**—This is one of the old-fashioned plants that might with advantage find a place more often than it does in summer bedding, for, although by no means so brilliant in its colouring as many things, it is sufficiently so to make a very attractive bed. It is seen to advantage as a carpet plant among a few pyramidal or standard Heliotropes. Introduced from Mexico in the forties, it was probably first grown in the ordinary greenhouse or conservatory, but its adaptability for outdoors during the summer months must have been quickly recognised, for I remember it as a flower garden plant more than forty years ago. Another old plant that may be occasionally used in a similar way to the Cuphea is *Diplacus glutinosus*; it makes a charming bed when associated (slightly pegged) with clumps of the scarlet-flowered perennial *Lobelia*.—E. BURRELL.

**Some accommodating plants.**—In the Orchid houses at the Dell, Englefield Green, Surrey, the residence of Baron Schröder, there are several most interesting examples of plant culture, quite apart from those presented by the many unique and beautiful Orchids. It is not that the plants themselves are of any special merit, but from the positions in which they are growing they deserve notice. One would never think of looking for healthy luxuriant plants beneath the grating of a pathway in a hothouse, yet in some of the Orchid and plant houses here there is quite a beautiful green carpet exposed to view when the grating is lifted, and the plant that forms it is the well known *Selaginella denticulata*. One often sees this used in a winter garden or conservatory as a covering for the bare soil between various plants, but even in such positions it is not always a success. To see the luxuriance with which it is growing in the above-mentioned curious and, one would think, anything but suitable place, it would appear that the deepest shade and any amount of moisture were the only requisites for its unqualified success. Many ornamental-leaved Begonias, in numerous beautiful varieties, were also thriving along with the Selaginella. That it is dark beneath these pathway gratings goes without saying, and a tremendous quantity of water must fall there throughout the day from the continued damping of the walls, floors, &c., but it evidently suits the Begonias and Selaginella perfectly. Rarely if ever have I seen the varieties of *Begonia Rex* (and they are now many and beautiful) grown so well and made such excellent use of as by Mr. Ballantine in the numerous plant and Orchid houses at the Dell. In the rockery under glass they are splendid, their leaves are giant ones and charmingly marked and coloured. Some of the best varieties were, I believe, obtained from Messrs. Sander and Sons, St. Albans, in the first place; when established they may easily be propagated. Under the stages also these Begonias are quite at home, forming a delightful ground covering and a pleasant change from the usually bare and ugly appearance of this portion of the house. Other beautiful little plants thriving most luxuriantly beneath some of the stages in the *Odontoglossum* and other houses are the *Fittionias*—*F. argyroneura*, with silvery veined leaves, being especially good. It quickly spreads and completely hides the ground from view. Were Mr. Ballantine's methods more generally adopted Orchid houses would more often be things of beauty when the Orchids are out of flower than is the case, at least they would be less commonplace.—A. P. H.

**Proposed vegetable exhibition at the Westminster Drill Hall, 1903.**—The following circular has been sent to the trade:—“The council of the Royal Horticultural Society having consented to set apart one of their fortnightly meetings at the James Street Drill Hall, Westminster, next autumn for an exhibition of high-class vegetables, we beg respectfully, as the promoters of the same, to ask you whether, subject to acceptable conditions, your esteemed firm would kindly consent to offer prizes for a class of vegetables at the said show. Our sole object is to secure for vegetables (most important of garden products) far higher recognition than they have hitherto received in London, and to that end we

wish to see at least one such exhibition held under the auspices of the Royal Horticultural Society annually, and alternately for late vegetables in September and for early ones in July. The council will not offer prizes; hence we are compelled to invite the kind co-operation of the seed trade. We do not wish for high prizes or large classes, but one at least to be fully comprehensive should include eighteen kinds, others being for twelve, nine, and six; also several classes for single dishes, and especially a class for salads. We would also desire to see one or two open classes for cottagers' vegetables. We think that there will be ample space in the present Drill Hall, not only for such classes as are named, but also round the sides for collections of choice vegetables, within rigidly prescribed limits, exhibited by firms contributing prizes. Such collections should greatly help to create a remarkably representative display of vegetables. It is needful, however, clearly to intimate that the council of the Royal Horticultural Society offer strong objections to some of the conditions usually imposed in schedules in connection with trade prizes, and to overcome these objections and thus enable what should be an unique display of vegetables to be held in London annually, we respectfully submit that each firm or seedsman offering any prizes be content to require that competitors for the same ‘must be their customers.’ Such condition we think should be regarded as sufficient and quite unobjectionable. As the council's arrangements for the ensuing year are now in course of preparation, and in which publication all vegetable prizes and classes will be inserted, we ask you kindly to favour us with an early reply.—EDWIN BECKETT, *Aldeham House Gardens, Elstree; ALEXANDER DEAN, Hon. Secretary, 62, Richmond Road, Kingston-on-Thames.*”

**Kitaibelia Lindemuthii.**—This has done very well, having stood the winter perfectly. Its weak point is that those parts of the foliage from which the chlorophyll is absent, or where it is more or less deficient, are liable to burn, but it is chiefly the oldest leaves that show this tendency. Having saved a score of seeds last year they were sown this spring, the result being a dozen plain green-leaved plants, without a trace of variegation. As the graft is so thoroughly permeated by the sap of the stock, I thought there were fair reasons for hoping the seedlings might share the variegation, but facts do not so far confirm the theory.—W. THOMPSON, *Ipswich*.

**Notes from Bournemouth.**—The Public Gardens are now looking their best. Starting through the first, one is struck by the large round beds on each side of the path, each bed matching the opposite one. The beds of Cannas—two of red and two of yellow—are perhaps the handsomest in the gardens. Then there are beds of Fuchsias, tall and graceful, and Zinnias of all colours, edged with French Marigolds and Begonias so full of bloom that there is scarcely a leaf to be seen. Then one comes to the two end beds of large, many-coloured double Scabious. Further on, in the next garden, the stream which flows through all widens out into several pools to form a rock garden. This part of the garden is fenced off and the gates padlocked, so that the soft green turf is not worn, and the brown ducks swim in the pools undisturbed. Higher up this garden is a bed of Aloes in flower. In all of the gardens there are clumps of Tritoma, some fully out, but most of them coming, and clumps of Montbretia, which thrive in the mild climate. Here and there to lighten the dark green of shrubberies are tall Gladioli sending up their bright spikes of flower. Most of the private gardens are bright with flowers of all kinds, large African Marigolds, Fuchsias, and Hydrangeas. Of the two last, I saw some splendid Fuchsias grown into trees almost, quite 4 feet high, and the flowers drooping in a shower from what one might almost call the trunk. The Hydrangeas, one particularly, were nearly sky blue. In the reservoir are some pretty white Nymphaeas just now in full bloom. Going on to the wild flowers, the cliffs are covered with Heather (just beginning to fade), Bracken, Gorse, Blackberry bushes (the fruit just ripening), and always a background of Pine trees.—A. SMALLPEICE.

**Pear Triomphe de Vienne.**—A Pear that is a constant bearer under any mode of training and produces large fruit of excellent flavour is the one named above. It is likewise a free and vigorous grower, making excellent specimens in a comparatively short time. The fruits come into use in September, after Williams' Bon Chrétien. It succeeds well here as a single cordon on an east wall, the fruits being large and of good flavour. I well remember what splendid crops of fruit on pyramid-trained trees Mr. H. Markham used to get of this variety when he was at Mereworth a few years ago. It is a variety that can be recommended to amateurs and gardeners alike when about to do some planting.—J. G., *The Retreat, Cam.*

## THE FLOWER GARDEN.

### CARNATIONS FROM SEED.

**F**EW things in a flower garden are more interesting than a bed of seedling Carnations; they are a source of the greatest pleasure both to the grower and his friends; they provide an abundance of blooms for cutting, and besides this there is always the chance of raising some new variety which will be even more beautiful than those already in existence. The first and most important thing is to procure good seed from some well known grower who saves it only from carefully fertilised flowers of the best varieties. Sow it in a box of fine prepared soil in March, and place the box in a hot house or garden frame with some bottom heat where it will soon germinate, and when the little seedlings get their second pair of leaves, and are large enough to handle, prick them out into boxes of good prepared soil and place them in a frame until they show that they have got hold of the new soil, then gradually harden them off, and eventually, about the end of June or early in July, plant them out in beds of deeply-dug rich soil about 18 inches apart where they are to flower the following season. During the winter they will want little or no attention. In the spring the soil should be occasionally stirred to keep down weeds, and the plants should be given a good dusting over once or twice after rain with soot mixed with wood ashes. This helps to keep off wireworms, slugs, and other pests, and acts as a good manure also. Beyond this there is only the staking of the flower-stems, and, of course, the necessary watering in dry weather, and it is most important not to let the roots get too dry.

This raising of plants from seed may seem a long process, but patience is everything in gardening, and the reward will come when you see your plants showing a mass of buds, and you eagerly scan them every morning and criticise the flowers as they open. Now, one word of warning—you must not expect too much; there will be many that are not worth keeping, owing to the flowers being badly formed, and there will be a certain percentage of singles; but amongst the rest there should be, if the seed has been good, a nice lot of plants that you can layer for producing plants to bloom the next season, and these layers you will find are mostly stronger and naturally more likely to suit your climate and soil than plants you can procure elsewhere.

When you have determined which of the seedlings come up to your idea of what a Carnation should be, you should mark them and make a note of their colour and habit of growth. Next comes the layering, which is generally done about the end of July or the beginning of August, and which process I will

shortly describe. You will require a sharp knife, some layering pins or pegs, and some fine prepared soil mixed with road scrapings or leaf-mould and sand. You will then carefully select the best shoots round the collar of the plant and nearest the ground, and cut away the rest (these, if thought advisable, may be struck as cuttings), thus freeing the plant as much as possible of all growth except the shoots you intend to layer and the flower-stems. Do not attempt to layer too many shoots, since if you do they will be apt to get too crowded when they begin to grow and so become a prey to disease. Next strip off the leaves from the shoots you intend to layer up to the third or fourth joint from the top, take your knife and make a clean cut halfway through the joint next below the one to which you have stripped off the leaves, and with a turn of the knife continue it in an upward direction as far as the next joint, thus forming a tongue, then bend the shoot carefully down and peg it firmly about an inch deep into the soil, which should have been previously loosened to a depth of 2 inches or 3 inches and have had a little of the prepared soil added to it. Repeat this process until you have a circle of layers all round the plant, then water them well with a fine rose, and keep them watered until they are well rooted and ready to plant out in their flowering beds, which will probably be about the end of September or beginning of October.

These layers will, the succeeding season, make strong plants, and, although they will not give the same profusion of bloom as their seedling parents, my experience is that they do better than plants which come from a strain that has been propagated from layers for a greater number of years. Now, I do not for one moment mean to say that I would advise you to neglect the many excellent old border varieties, but I would have you supplement your collection with a few seedlings, and I feel sure that you will never regret the little care and attention you bestow upon them.

*St. Asaph.* W. A. WATTS.

[Mr. Watts kindly sent the beautiful seedling Carnations noticed in THE GARDEN on September 13, and the photograph of that fine white George Maquay.—ED.]

#### BORDER CARNATIONS.

Now the Carnation season for 1902 is over, one can profitably perhaps jot down a few notes, more particularly with reference to the newer kinds grown last season for the first time, not forgetting those whose acquaintance we have not yet made in the garden, but which will be sent out this autumn. I cannot help wondering sometimes whether all the new flowers that one sees are really improvements: but if care is taken to see them—as they must be seen—growing, then comparisons can be fairly made. It is a mistake to take an individual bloom (such as one sees at the shows) and order that variety unless it is grown for exhibition only. I am not professing to write from that point of view. This article, then, only considers the Carnation as a garden flower and not as a show bloom. What I want to point out is, that in Carnations as in Roses, we are getting from the raisers and distributors of the new varieties many flowers that, while indispensable for show, are really equally indispensable for the garden. No one who has tried the new Carnations, such as Trojan, Miss Audrey Campbell, Agnes Sorrel, Lady Hindlip, &c., is likely to be content with the old varieties, such as Raby Castle, Gloire de

Nancy, Alice Ayres, &c., and yet I am bound to admit that in six gardens out of seven it is the old Carnations that are grown, presumably from lack of knowledge. True, the initial cost is slightly more, but taking into consideration the increased number of layers one can get from the newer varieties, to say nothing of the finer quality and greater quantity of the flowers, the best are much the cheapest in the end.

All the varieties named have been grown by me out of doors, and were all planted last autumn (some from my own layers), and received no protection from the weather, but were grown naturally in a good light loam. Town growers will find that the sparrow does much mischief unless a plentiful lot of black cotton is used.

With one or two exceptions the whole of the Carnations mentioned below were raised by Mr. Martin Smith, and sent out by Mr. Douglas; they are all robust growers, with calyces that do not burst. I propose dividing them into their natural classes, and will commence with the

#### SELF CARNATIONS.

*Whites.*—I saw a note in THE GARDEN on September 13 with reference to a white Carnation called George Maquay. The writer put it *fusile principis*. I am sorry I have not come across it, because I have always wanted a good white, and was never content until I met with Trojan; this variety is really first-class. The photograph accompanying these notes was taken in August after the plants had been in flower about three weeks. A careful inspection will show that all the best flowers and crown buds have been picked; the grass is very strong and of beautiful colour. Other good whites are Hildegarde, The Briton, Much the Miller, and Ensign (the last two best for exhibition).

*Red and Scarlet.*—Lady Hindlip is a brilliant crimson-scarlet, with fine form and petals. One of the best of this colour, another excellent flower, is the Cadi, rich scarlet with well formed petals and fine outline. Tabley is a good flower of large size. Quentin Durward is very vivid but not quite so robust a grower. Mrs. Macrae is darker, and then we come to Agnes Sorrel, Gil Polo, and Nox, the darkest of all. Agnes Sorrel is the best grower of the three, Gil Polo having perhaps the better flower for exhibition. Nox requires shading, otherwise it quickly burns like the dark red Roses.

*Pinks.*—The shades of pink are innumerable, and it seems to be the favourite colour. Most people seem to prefer a pink Carnation to that of any other shade. Blushing Bride is one of the pale ones; Lady Nina Balfour is blushing pink, not such a good grower; Miss Schiffner is one of the best flowers, large and scented; Mrs. James Douglas is quite the best of its shade, a deep salmon-pink; Rose Celestial and Asphodel are both good; Bomba and Sapho are much alike, with a preference for the latter.

*Yellows.*—Miss Audrey Campbell does as well with me as any of the yellows. Cecilia is finer, but not so strong or as free blooming. Almoner is excellent in the petal and a large flower, sometimes coming deeper in the centre. Of other selfs Midas is the best orange-coloured flower, that sometimes comes nearly scarlet.

*Lavender and heliotrope.*—I think Lady Jane Grey has proved the best of these curious coloured flowers, that are quaint rather than beautiful, Garville Gem being not quite so satisfactory.

#### THE PICOTEES.

These, especially the yellow grounds, I am very fond of. It is not so long ago that I gave

up as a hopeless task trying to grow yellow ground Picotees out of doors; but the following all wintered well with me this year, showing the great improvement in the constitution of these flowers that has taken place since Mr. Martin Smith took them in hand.

Childe Harold is one of the new flowers that has been exhibited a great deal this season; its margin is very good, a deep rose in colour; The plant is vigorous. Argosy is another fine flower, but I found that most of my flowers came with a splash or two on the petals that makes it more of a fancy than a Picotee, under which latter title I believe it was sent out. Effie Deans is a very fine grower, but this too has the same fault of slight splashes. Empress Eugenie, although not of very recent introduction, is still one of the best. Glee Maiden and Gertrude are excellent. Lanzan is also hard to beat, and very useful, fine form, of good colour, with an edge of purple. Mrs. Tremayne is an excellent heavy edge, with a ground of deep yellow. Lady St. Oswald, bright red margin on rich yellow; distinct, good. Huella, a new and very pretty flower, not a fine Picotee, but too pretty to be discarded altogether.

Of the fancies there are many flowers very beautiful individually, but they are not so good in the garden as the self. Still, I would not be without those named. Charles Martel is good, having a white ground instead of the more common yellow. Hidalgo is very fine and a great favourite for exhibition; a great number consider it the finest fancy ever raised; it sports a great deal. Czarina, a distinct, well marked flower, yellow ground and bright scarlet. Mrs. Charles Baring is another heavily marked flower. Queen Bess has been on many winning stands, and is excellent with me. Sweet Lavender is another good grower. Miss Mackenzie is very difficult to beat for prettiness; it is not so large or correctly formed as some, but its delightful colouring makes it a great favourite.

I cannot conclude these notes on border Carnations without a word as to growing them from seed. I planted out about 100 strong plants last autumn in October, and there is something very fascinating in this method of growing the Carnation—one never knows what may turn up. One certainly gets a proportion of singles, I should say possibly 30 per cent.; but they are very beautiful—I had a single yellow this year that was very lovely—and they are really as decorative as the doubles. Of these I had three plants that I am propagating from. They are, I think, distinct, but not good enough for show. If one has not sown the seed, any of the Carnation growers will supply seedlings at about 3s. 6d. per dozen, but it is as well to go to a specialist; one gets much finer flowers, not to mention plants.

HERBERT E. MOLYNEUX.

*Brantwood, Dulham, S.W.*

[George Maquay is a beautiful white. It was figured in THE GARDEN, September 13, page 177.]

#### SWEET VIOLETS—OLD AND NEW.

(Continued from page 176.)

##### WINTER TREATMENT.

In the southern counties the double Violet will survive our winters, but the plants are so crippled by severe frost that few, if any, flowers can be expected, therefore cold frames or pits must be provided. Those in which Melons or Cucumbers have been grown during the summer will answer the purpose admirably, as the exhausted Melon soil will serve as an excellent medium for planting the Violets in. The Violet plants when planted should be within 6 inches of the glass, so that more soil will have to be added if necessary to

bring the plants to this height. Before the plants are taken up from the border they should receive a good soaking of water the day before, and they must be taken up with a ball of soil as big as the plant itself. In planting pack them close together, in order to get as many plants in the frame as possible, so that when they are in bloom the surface of the frame or pit will be wholly covered with flowers. Immediately after planting the plants should receive a good soaking of water, the lights placed on, admitting plenty of air, and the pits shaded for a few days to prevent flagging. In a week or ten days they will have recovered from the effects of the moving, and the shade must be discontinued, and as long as the weather continues mild and warm the lights should be left off the frames and the plants exposed to the weather day and night. Early in October frost may be expected, when the lights must be placed over the Violets at night, leaving plenty of air on, unless danger of frost is apprehended, when they should be closed the last thing at night. During severe weather in winter the frames must be covered with mats or some

double will answer equally as well in the case of the single varieties. It should be propagated at the same time and in the same way, except that it is not necessary to pot the young plants after they have been divided and taken from the parent plant. The stronger the small divisions are and the more roots they possess the better plants will they make in summer. They succeed best in the same aspect as recommended for the doubles (north-east, with partial shade), and the border for these should be enriched with a liberal dressing of rich, short manure, as well as an addition of leaf-soil, lime, and road scrapings. Instead of digging the land in the ordinary way it should be bastard trenched, that is, the top spit turned over, and the bottom spit also turned over and left at the bottom.

The single varieties grow much stronger than the double ones, and therefore they must be planted further apart, 3 feet each way being none too much for such varieties as Princess of Wales, California, La France, and others of this class. They attain such a size by the autumn that they more than meet even at this distance, and

foliage, and above all to have a good ball of earth to the plant at the time of replanting into pits in the autumn.

*Princess of Wales.*—This variety was introduced into English gardens a few years ago from Hyères. The flower is of large size, and carried on a foot-stalk often from 9 inches to 1 foot in length. A robust grower, quite hardy, a lovely blue, and deliciously scented.

*La France.*—As large as Princess of Wales, of a darker shade of blue. In many respects this is undoubtedly the best single blue yet introduced, and should be grown in every garden.

*California.*—Introduced from America a few years ago. It is a handsome variety; in growth and habit much like the two above mentioned, but inferior to both in every respect.

*Princess Beatrice.*—Like the above, only of dwarfer habit and later in blooming.

*Admiral Irrellan.*—One of the most distinct and valuable single Violets we possess. It is of purple colour, with a distinctly red shade, well deserving of a frame in winter, when abundance of flowers in their distinct shades of purple will be available.

*Princess de Sunone.*—An Italian variety, sweetly fragrant and beautiful. The flowers are white, flaked with blue.

*Sulphurea.*—Sulphur-coloured novelty.

*White Czar.*—The only single white worth growing.

OWEN THOMAS.

SELF CARNATION TROJAN (WHITE) IN A SUBURBAN GARDEN.

(From a photograph kindly sent by Mr. H. E. Molyneux. Many flowers had been gathered before the photograph was taken.)

other covering to a sufficient depth to keep out frost. It is fatal to use fire-heat at any time in the growth of the Violet. The first flowers will appear towards the end of September, and in increased numbers through October and November, but not so many usually during December and January, as the plants are then in a more or less dormant state; but as soon as February comes (if they have wintered all right) flowers appear more abundantly until well into April, when the season is over and the plants are ready to be again propagated. Thus comes to an end the detail of the cultivation of the double Violet for one whole year.

#### THE SINGLE VIOLET.

This is harder, and may be profitably grown in the open air as a market crop, but the quality and quantity of flowers are better when under glass and treated in the same way during winter as for the double Violet. In treating of the cultivation of the single Violet, I will only touch on those points where the conditions and culture have to be varied slightly to meet special requirements. Beyond this, the details given in the culture of the

when lifted in the autumn for planting in pits they have a ball of earth attached as large and heavy as a man can carry. I said before that there is no advantage in potting up the young divisions of the single varieties at propagating time. Instead, they may be at once dibbled into the prepared border in the same way that Cabbages are planted. Once planted in their summer quarters the same routine of culture should be followed as recommended for the double variety, and if the best is to be made of them they should be replanted into cold pits in the early autumn the same as advised in the case of the others. Should this not be possible, these sorts will give a good return out of doors during the autumn and winter and in spring, towards the end of March and through April, they will furnish abundance of bloom; they are perfectly hardy.

The following conditions should be observed in the cultivation of the Violet if the best results are desired: Pure air, partial shade, well drained and well cultivated soil of not too heavy texture, immunity from red spider, the provision of divisions in spring, with a good supply of roots and healthy

are the only sinners. In plenty of larger gardens the same plan unfortunately is followed. A heap of soil or rubbish is thrown up; it is studded with stones and a few plants, and the rock garden is finished. I know hundreds of instances in which the work was carried out precisely on these lines, and it is no wonder that—with such examples of bad taste before them—the owners of many estates are altogether prejudiced against rock gardens of any kind, even when the site and its surroundings are suitable for the purpose.

It may be argued that gardens on sloping ground would often make stonework necessary in order to keep up the soil, &c. This I willingly admit, but in most cases simply a plain wall would have been more suitable. In the case of a terrace wall, the latter can be adorned with all kinds of choice flowering creepers. If

[\* With this article we open a series of practical essays on the construction of rock gardens, illustrated by numerous drawings and photographs, by Mr. F. W. Meyer.—Ed.]

## THE ROCK GARDEN.

### ROCK GARDEN MAKING.\*

#### I.—INTRODUCTION.

Of all the numerous branches of horticulture there is, perhaps, none more abused than the making of rock gardens. Many

are the instances in

which an otherwise pretty garden has been spoiled by so-called rockwork badly constructed and utterly out of character with its surroundings. It must be borne in mind that no rocks of any kind can possibly be an ornament to a garden unless they are either natural or appear to be so, and are associated with suitable plants.

Can anything be more hideous than the average villa garden on sloping ground, where, in spite of regular outlines generally, rockwork is introduced in the shape of actual rows of stones almost uniform in size, and placed mostly upright on their ends? But builders and "jobbing gardeners" still vie with each other in putting up these monstrosities. Nor

are they the only sinners. In plenty of larger gardens the same plan unfortunately is followed. A heap of soil or rubbish is thrown up; it is studded with stones and a few plants, and the rock garden is finished. I know hundreds of instances in which the work was carried out precisely on these lines, and it is no wonder that—with such examples of bad taste before them—the owners of many estates are altogether prejudiced against rock gardens of any kind, even when the site and its surroundings are suitable for the purpose.

It may be argued that gardens on sloping ground would often make stonework necessary in order to keep up the soil, &c. This I willingly admit, but in most cases simply a plain wall would have been more suitable. In the case of a terrace wall, the latter can be adorned with all kinds of choice flowering creepers. If

stonework is absolutely necessary to keep up the sides of paths or drives, it would be better to erect a plain "dry" retaining wall, in which the joints would be filled with good soil instead of cement or mortar—this would be admirably adapted for "wall gardening"—than construct a long and narrow line of rockwork which could never look natural in such a position.

A wall garden may be made very beautiful and interesting, and a rock garden which has an absolutely natural appearance may be made more beautiful and more interesting still. But the fact cannot be too strongly emphasised that the horrid structures referred to above, which are neither one thing nor the other, *i.e.*, which resemble neither wall nor rock, are absolutely out of place, and without being entirely reconstructed they can never be transformed into a thing of beauty. The subject of wall gardening will be dealt with separately under the heading of "Wall Garden Making." I propose under the heading of "Rock Garden Making" to give a series of essays dealing systematically with this interesting subject, giving practical hints based on actual experience. This, I hope, may be useful to others, and assist them in deciding what to do and what to avoid. I do not for one moment wish to recommend my method of construct-

is furnished with plants from the Himalayas or Norway, Switzerland or Colorado. The all-important point is that it must be absolutely natural in appearance, and therefore in harmony with its surroundings.

Without this last-named condition the ground can never be a proper rock garden in the true sense of the word. It may have stonework covered by plants of the coarser kinds; we may have elaborate cement or plaster works somewhat resembling rocks, on which, however, no plants can grow. But in all such work the greatest charm of a rock garden—viz., natural simplicity—will be absent, and for this reason, a really natural-looking rock garden of only a few yards in extent will be infinitely more pleasing to the eye than the most extensive or the most elaborate structure which does not comply with these conditions, but betrays its artificial origin at a glance.

A rock garden enables us to cultivate a very much larger variety of plants than it would be possible to obtain from ordinary beds or borders. It can be so arranged as to be a source of delight practically all the year round. It will enable us to grow even the minutest gems of the alpine flora, more especially as the moist climate of these islands is such that in some instances alpine plants, if properly planted, will grow even better than in their native home. A rock garden, properly constructed, should be of that wild and rugged character which is so fascinating in the works of Nature, and though we can never introduce into our gardens the majestic grandeur of the Alps, we can at least have ground which is picturesquely treated and broken up so as to represent mountain scenery in miniature. Since we have mountain plants from all quarters of the globe at our command, our picture can make up in variety what it may lack in grandeur.

It must not be supposed that in planting a rock garden we must restrict our choice of plants to those

or small scale can be made without having the additional advantage of running water.

From the foregoing it must not for one moment be inferred that a rock garden is essential in every garden, large or small. On the contrary, the introduction of rockwork into some gardens would be absurd, if the surroundings are not such as would be suitable to a more or less rugged treatment. My argument is that nothing can be prettier or more desirable than a well made rock garden in the right place, but also that nothing could possibly be worse than rockwork out of place.

It is with a view of arriving at some satisfactory solution of the problem as to how to deal with various grounds and under varying conditions, that I propose to go fully into this matter in the following chapters on "Rock Garden Making."

*Elmside, Exeter.*

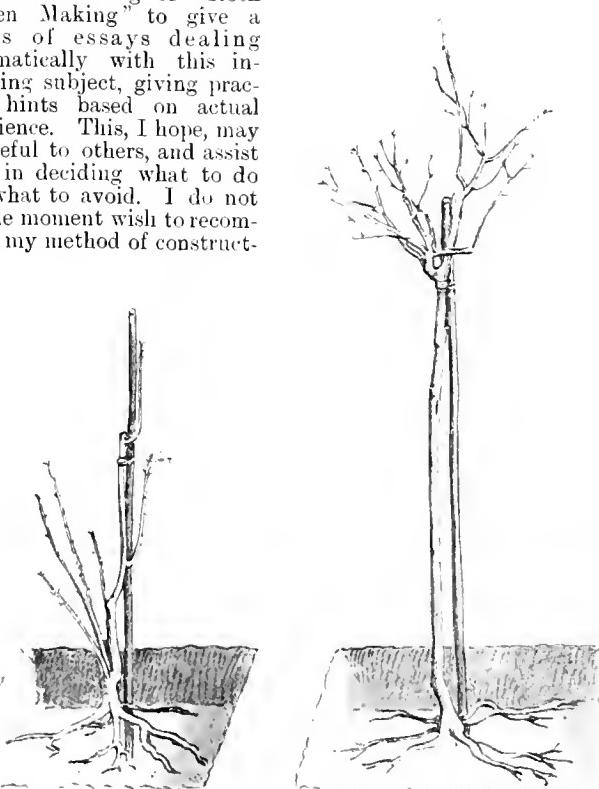

F. W. MEYER.

## THE ROSE GARDEN.

### PLANTING ROSES.

AS the time is approaching for Rose planting, we cannot do better than quote the excellent remarks of Mr. Mawley in "Roses for English Gardens," and reproduce two illustrations. The beds must be prepared as recently advised in THE GARDEN.

Actual planting "can be undertaken at any time between the beginning of November and the end of March, but the best time of all is early in November. Should the ground be sodden or frozen when the Roses arrive, the planting must be deferred until in the one case the superfluous moisture has passed into the subsoil, and in the other until the frost is quite out of the ground. In order to prevent the exposure of the roots to sunshine or drying winds, it will be a good plan to take only a few plants at a time from the place where they have been heeled in, and to place a mat over them when brought to the side of the bed. A square hole for each plant should be made, not more than 6 inches deep and sufficiently large to hold the roots when spread out horizontally. A plant should then be taken from beneath the matting and placed in the hole, taking care to spread out the roots evenly all round. Some fine soil, free from manure, should next be worked with the hand between the roots and above them to the depth of 3 inches, and afterwards trodden down with moderate firmness so as not to bruise the roots. After adding more soil, that in the hole should again be pressed down, more firmly this time, and a final treading given when the hole is filled up. Firm planting is of the greatest importance to the after welfare of the plants. In planting Roses intended for exhibition, or where extra attention can be given them, it will be well to place a little leaf-mould at the bottom of each hole, and to work in among and above the roots a few inches of the same material instead of the fine soil. Failing leaf-mould, some finely-chopped fibrous loam may be used; if of a somewhat gritty nature so much the better. In each case a small handful of bone-dust should be sprinkled over the layer of leaf-mould or fibrous loam. The principal advantage of these additions is that they enable the plants to become more quickly established. It also allows of the planting being proceeded with, when, owing to the wet nature of the soil in the beds, it would not be otherwise practicable. No manure should be

METHOD OF PLANTING BUSH AND STANDARD ROSES.

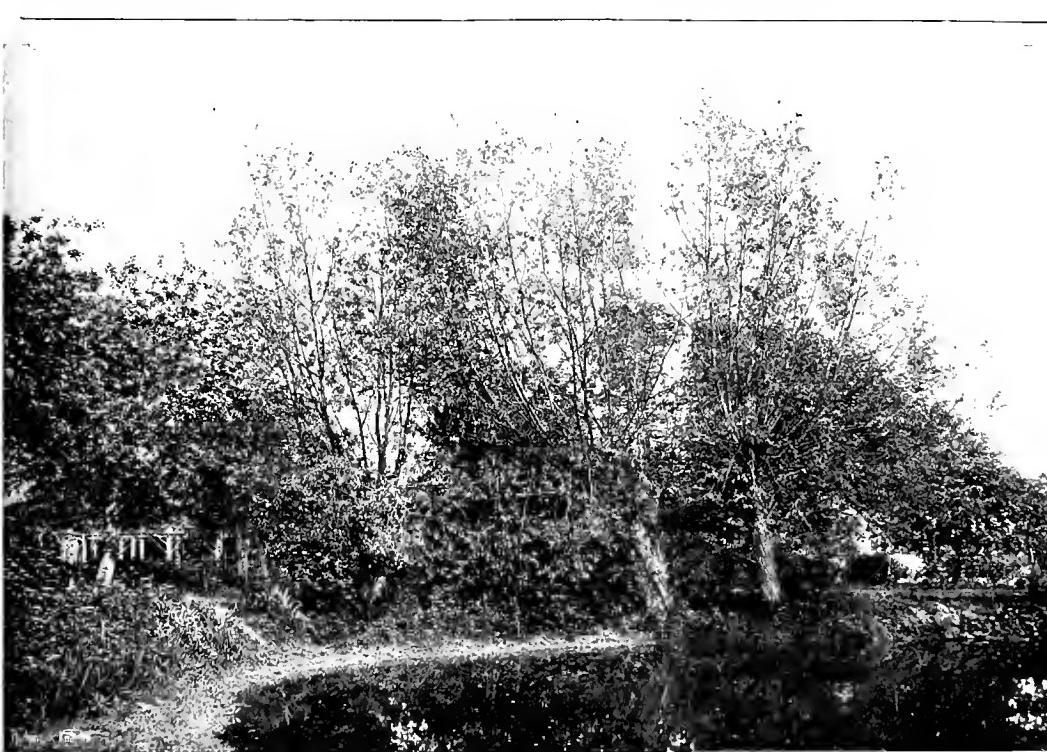

ing rock gardens as right and condemn all other methods as wrong, but I will merely give the result of my own experience, and will enquire into the principle of the theory and practice of rock garden making according to the lessons taught by Nature, and I will leave others to draw their own conclusions.

#### WHAT IS A ROCK GARDEN?

A rock garden is that portion of a garden which contains either natural rocks or rocks artificially arranged in such a way as to appear natural, and on which mountain plants of all kinds can thrive. It is not a question of size, or of the kind of rock, or of the kind of plants to be used. These are mere details, depending on circumstances. It matters not, therefore, whether the rock garden is many acres in extent or only a few yards. Neither does it matter whether it is composed of granite, limestone, or any other rock, or whether it

from certain districts only, just because we find them so associated and distributed in Nature. This would be going decidedly too far. There is no reason why we should not improve upon Nature, and, if we have embraced a chance of embellishing our rock gardens with plants from various zones, we have taken a forward step in that direction, for we can by that means prolong the flowering season and make our rocks practically an attractive feature in the garden, even at a season when the rest of the garden is dull and uninteresting.

Many people are of opinion that rocks to be picturesque must invariably be associated with water. Water in almost any form imparts life and light into the landscape, and into the rock garden in particular. But visible water is not indispensable, and in the following essays on "Rock Garden Making" I hope to show that very pretty rock gardens on a large

WILLOWS BY WATERSIDE.

allowed to come in contact with the roots themselves at the time of planting. The roots when they become active will soon find out the manure and appreciate it, but in a dormant state it is more like poison than food to them.

#### PLANTING CLIMBING OR PILLAR ROSES.

These strong-growing varieties are often treated as if they could take care of themselves, and therefore require less care in planting than other Roses, whereas the contrary is the case. The hole made to receive them should be 2 feet 6 inches square and 2 feet deep. The existing soil, if fairly good, should be enriched with a liberal addition of farmyard manure, and the planting proceeded with as described in the previous paragraph. If the natural soil, however, be poor and thin, some of this should be removed altogether and better soil substituted. The reason why these extra vigorous Roses require a larger quantity of good soil is because the roots have to support a much larger plant, and as a rule they are intended to occupy the same position for a great number of years."

#### THE BEST ROSES OF THE SEASON.

In compliance with the request in your paper of the 6th inst., I send a list of two dozen Roses that have done well here this season. Against house : Gloire de Dijon, Marie Henriette, Homer, W. A. Richardson. In beds: Ulrich Brunner, Duchess of Albany, Mrs. John Laing, La Francee, Captain Christy, Victor Hugo, Marchioness of Londonderry, Clio, Marquise Litta, Caroline Testout, Mme. Lambard, Souvenir de Catherine Guillot, Comtesse de Nadaillac, Killarney, Maman Cochet, Souvenir de S. A. Prince, Catherine Mernet, Mme. Chédane Guinoisseau, Princesse de Sagan, and Gustave Regis.

SOUTH DERBYSHIRE.

#### NORTH OF ENGLAND.

HERE in Yorkshire Roses have been very late and in many cases disappointing, the cold nights in July and August probably being the reason. Since September came in the Tea Roses on the south walls have been much better. The best twelve Roses I find in the North of England are, for either

beds or walls : Nipheta, Marie van Houtte, Hon. Edith Gifford, Viscountess Folkestone, Lady May Fitzwilliam, Docteur Grill (on wall), Mrs. W. J. Grant, Caroline Testout, Killarney, Liberty, Antoine Rivoire, and Malmaison. If I could only grow three Roses I should choose Marie van Houtte, Nipheta, and Viscountess Folkestone.

Stockton Hall, York.

P.

#### GOOD CLIMBING ROSES.

I FIND the following Roses succeed well here : Rêve d'Or, W. A. Richardson, Reine Olga de Wurtemburg, Longworth Rambler, Euphrosyne and Dawson Rose (both good on old trees), Mme. Alfred Carrière, Aglaia, Aimée Vibert, Bouquet d'Or, Céline Forestier, and Dundee Rambler.

#### SINGLE ROSES.

Polyantha grandiflora, Moschata nivea, Moschata alba, Carmine Pillar (beautiful on a dead tree), Paul's Single White, Irish Beauty (always in flower), Anne of Gierstein, Amy Robsart, and Meg Merrilies. Purity I consider an excellent Bourbon to cover low walls.

Sunning.

J. S.

#### TWENTY BEST ROSES FOR BUTTONHOLES.

IN response to several requests we give the following selection of buttonhole Roses. As so many of our Roses of the present day yield beautiful buds it is somewhat difficult to select twenty from such a large number. The following selection can be highly recommended for their superb buds and also for their freedom in blossoming :

Anne Olivier, rosy flesh and buff.

Bouquet d'Or, pale yellow with copper centre.

Bridesmaid, beautiful clear pink.

Duke of Albany, vivid crimson.

Fisher Holmes, crimson-scarlet.

Gloire Lyonnaise, pale lemon.

Gustave Regis, canary yellow.

Killarney, flesh white, suffused with pale pink.

Kaisserin Augusta Victoria, pale primrose colour.

Liberty, brilliant velvety crimson.

Mrs. W. J. Grant, imperial pink. If possible grow the climbing form as a pillar Rose.

Mme. Abel Chatenay, carmine-rose, shaded salmon.

Mme. Charles, bright apricot.

Mme. Pierre Cochet, deep orange-yellow.

Mme. Hoste, bright clear yellow.

Nipheta, snow white.

Papa Gontier, rosy crimson.

Souvenir du President Carnot, rosy flesh, shaded white.

Victor Hugo, glowing scarlet-crimson.

White Maman Cochet, pure white, tinged with blush.

#### WILLOWS.

AMONG the many things which attract the attention of garden-loving people none are so easy to get and grow as the Willows, which, however, we so often see neglected. Some of the garden forms are grown, but frequently the finest native tree Willows do not take the place in garden pictures they deserve, such as the yellow-barked Willow and its red form. The Weeping Willow, which is a characteristic tree in certain parts of England and Ireland, is much less seen about London, owing probably to its being somewhat tender, otherwise why is it not grown? People who have the opportunity of planting these things along rivers and streams and in marshy ground have some of the most charming foliage to wander amongst at this time of the year that any trees produce.

A very interesting Willow is *Salix blanda*, which Baron Von St. Paul tells us is harder than the Weeping Willow and a noble tree. Amongst the other Willows lately planted by us in groups by water we may mention *daphnoides* with purple shoots; *Sieboldii*, which is a very free and promising Willow; *Salmoni*, *lucida*, *cæsia pendula*, and the various forms of the White Willow, such as the Huntingdon and Bedford Willows. The American Willow is a charming little tree, but owing to its being grafted on the common Sallow it takes a great deal of trouble to keep the suckers from killing it.

Now that trees and shrubs are being more planted in gardens we hope the many beautiful Willows will not be forgotten. The golden and red-barked varieties of *S. vitellina* are charming for their winter colouring. These, though scarcely ever seen, are capable, when properly treated, of producing bright warm effects that are especially charming from November to February. When allowed to grow naturally this Willow—known popularly as the Golden Osier—forms a graceful tree of large size. Its twigs have a golden or red tinge, according to the variety, but on fully grown trees these twigs are not large. To obtain a bright patch of colour plant these Willows in good-sized groups.

#### ROUND ABOUT A GARDEN.

##### DREAMS OF NEXT YEAR.

A MAN who is devoted to his garden seldom has the idea of colour arrangements for next year out of his head. Often in sleep he dreams of their surpassing loveliness; or, if he has dined not wisely but too well, his nightmare may take the shape of labels having been mixed and everything coming up where it should not—each colour killing the one next to it, tall flowers where short ones should be, and, oh, horror! Onions somehow thriving where the very choicest Tulips were expected. But, good or bad, the next year of his dreams is never quite fulfilled; nor, by a very long way, is the contemplated next year of his waking ambitions.

## THINK OF NEXT AUTUMN.

Florists fully understand the weakness of man's forgetful nature, so they bombard him at two seasons of the year—this is one of them—with elaborate catalogues. They know that in autumn the average garden needs "doing up" for next spring, and that in spring everyone begins to think of summer flowers. But those who wait to be reminded by the catalogues will never have much of a garden. It is only in spring, when you have your failures and successes in the spring garden before your eyes, that you can properly decide what to do for the following spring, and now is the time to think of next autumn. Consider your garden as it is, as a mere diagram of what it ought to be, with here and there a small space, perhaps, filled in exactly as you would wish it to be next year. Then do not rest until you have decided how all the remaining space is to be filled, and seize the earliest—not, as one usually does, the latest—moment for carrying your decisions into effect.

## A HACKNEYED TUNE OF COLOUR.

The chief defect of most gardens is the muddled arrangements of colour, or else the wearisome repetition of familiar schemes. The most aggravating of these in summer is the old three-fold combination of yellow Calceolaria, scarlet Geranium, and blue Lobelia. That it is surpassingly brilliant and "effective" is true, and if one invented it now for the first time one would be justified in flaunting it over the garden and inviting the whole world to come and admire. But it is so stale and familiar as to be positively irritating now, as even the most taking of tunes becomes

annoying when it is ground out by every barrel organ.

## THE MISSING FACTOR.

Besides, the ordinary gardener of to-day seems to have forgotten the one factor which made the Lobelia-Geranium-Calceolaria blaze of blue, red, and yellow, really beautiful and satisfying to the eye when it was first introduced. Then it was always relieved and softened by a backing of white Marguerites; but the modern gardener is generally satisfied with the gaudy colours by themselves. Indeed, you will very often see even the blue left out, and a dotted double line of red and yellow alone left to offend the sight along all the narrow borders of a garden. Yet we may learn from these failures of others how to succeed ourselves; and anyone who next year likes to fill the centre of a fair-sized flower bed with white flowers only, using the Lobelia-Calceolaria-Geranium arrangement as a comparatively narrow edging, will find that he has a thing of real beauty; for the expanse of white will balance the brilliance of the edging and give a novel charm even to that hackneyed trio of bedding plants.

## CONTRASTS AND HARMONIES.

The reason why the mixture of red, yellow, and blue is so brilliant and "effective"—i.e., productive of a maximum of display at a minimum of cost—is that each of these colours is the complement of the other two, and gains intensity from their presence; but you can get the same effect by using a single line of orange Nasturtiums, instead of Calceolarias and Geraniums, with the blue Lobelia. This as an edging to a white flower bed has the

advantage of being narrower, although you lose the crispness of the contrast between the scarlet and the white. It is the white, however, which alone makes either gaudy combination beautiful; and it is a safe rule in colour schemes for all seasons that wherever you use bright contrasting hues you should add plenty of white. You should have more white Tulips, for instance, than of any other colour: and there is no discord in the colours of flowers which white will not harmonise.

E. K. R.

## EREMURUS ROBUSTUS SUPERBUS.

MR. P. W. VOET, "Edenhof," Overveen, near Haarlem, sends an illustration of this hybrid Eremurus. Mr. Voet says it grows twice as high as *E. himalaicus*, and flowers much earlier. It was shown in June last for the first time under the name of *E. robustus superbus*, and was given a first-class certificate by the Dutch Horticultural Society.

## THE MOUNTAIN PRIMULAS.

(Continued from page 132.)

## PRIMULAS FOR OPEN GROUND OR GARDEN USE.

*P. ACUALIS* (Jacq.), syn. *P. vulgaris* (Huds.), *grandiflora* (Lam.), *sylvestris* (Scop.), *hybrida* (Schrank), *uniflora* (Gmel.), *breviscapa* (Murr.). Central Europe and the Mediterranean region.—Plant tufted, leaves large, obovate, diminishing to a winged petiole; flowers single on a weak stem; corolla pale yellow, scentless. January

EREMURUS ROBUSTUS SUPERBUS IN A DUTCH GARDEN.

PRIMULA ELATIOR.

(NEARLY LIFE SIZE.)

to August. This plant has given rise to a large number of the garden varieties grown in English gardens under the name of Primrose.

In the wild state flowers are found of bluish, rosy or red colourings, and hybrids. Willkomm has published *P. balearica* with quite white stemless flowers and leaves with the undersides glabrous. Reichenbach published the variety *Sibthorpi* from the Caucasus, with rosy flowers, leaves very downy beneath, and almost stemless.

*P. ambigua* (Salisb.), a syn. of *P. officinalis*. (Jacq.).

*P. amœna* (Bieb. non Lindl.), syn. *P. elatior* var. *amœna* (Duby), Bot. Mag. t. 3252. The Caucasus from 6,000 feet to 10,000 feet.—Very near *elatior*, from which it differs by its obovate leaves, whitely tomentose beneath in the young state, its crimson flowers and its pedicels set with bristling hairs. April and May.

*P. austriaca* (Wettst.).—A hybrid of *P. acaulis* and *inflata*.

*P. bosniaca* (Beck).—A hybrid of *P. acaulis* and *Columnæ*.

*P. carpatica* (Fuss).—A Carpathian variety of *P. elatior*, stouter and larger in all its parts.

*P. cashmiriana* (Hook).—A variety of *P. denticulata*.

*P. Columnæ* (Ten.), syn. *P. suaveolens* (Bert), *P. Thomasini* (Gren. and God.), *P. cordifolia* (Schur.), *P. discolor* (Schur.).—Considered by Pax and "Index Kewensis" as simply a variety

of *P. officinalis*. It is, however, very distinct, the leaf being suddenly contracted to a narrow petiole, and cordate at the base, whitely tomentose underneath in the young state and greyish when full grown, and the calyx bell-shaped. It grows in the Mediterranean region on the limestone and the basalt.

*P. cortusoides* (L.). Siberia, China and Japan. Figured in Bot. Mag. t. 399.—Leaves large, soft, ovate-cordate, crenate and almost lobed; flowers strong crimson, arranged in an umbel of five to twelve on a stem 6 inches to 8 inches long. April to June. Regel has published a variety *tomentella*, whose calyx is tomentose.

*P. denticulata* (Smith), syn. *P. Hoffmeisteri* (Klotz), *P. telemachica* (Klatt.). Himalayas, from Kashmir to Bhutan, from 6,500 feet to 13,000 feet, and in Yunnan.—A well-known garden plant that has been half a century in cultivation. Leaves lanceolate - elliptical, wrinkled, toothed, more or less mealy beneath; flowers lilac, small, numerous, borne in globular heads on a thick stalk 8 inches to 20 inches high. March to June. There are varieties with pure white and pale lilac flowers, one with leaves edged with white (*fol. var.*) and one with longer flowers of a deeper purple colour (*pulcherrima*).

*P. elatior* (Jacq.), syn. *P. inodora* (Gil.).—Occurring throughout Europe, especially in mountainous and woody places, except in the Mediterranean region. Figured in Reichenbach's "Icones XVII," t. 49. Leaves ovate-lanceolate, abruptly or gradually diminished to the petiole; flowers pale sulphur-yellow, not spotted with orange at the base; pedicels upright and of unequal length. April and May.

Pax has published a variety *genuina* with the calyx tubular-campanulate, and its teeth triangular and sharp, and the capsule cylindrical. Its synonyms are *P. lateriflora* (Gouy), *montana* (Opiz), *domestica* (Hoffm.), *subarctica* (Schur.), *crenata* (Schur.), *montana* (Schur.), *alpestris* (Schur.), and *pyrenaica* (Mieg.). Grenier and Godron have published the var. *intiscata* from the Pyrenees, with leaves obovate-elliptical or ovate, gradually diminishing to the wide-winged petiole, with the flower-stalk hardly ever longer than the leaves, with a narrow tubular-campanulate calyx, and a short cylindrical capsule of the same length as the calyx. Lehmann has published *P. Pallasii* from the Caucasus, with a very narrow tubular calyx with very narrow teeth

recurved upwards. There are still the varieties *cordifolia* (Gupr.), *perreiniana* (Flüg), and *macrocarpa* (Pers.), which I see are not in cultivation.

Since the end of the sixteenth century improved forms of this plant, called Oxlips, have been popular plants in English gardens. As it is extremely variable many fine forms have been raised, and are beautiful in the garden, especially in woodland and grouped among shrubs. But, except in England and perhaps Holland, I am not aware that the Oxlip as a garden plant is much known or appreciated. I had hoped to do well with them here (Geneva) from English seed from Wisley, Chislehurst, and elsewhere, but in our climate they lost their brightness. The Oxlip must be seen in England where it is at home.

Geneva.

H. CORREVON.

(To be continued.)

## THE INDOOR GARDEN.

### SOME GOOD FUCHSIAS.

FOR greenhouse decoration during the summer few plants excel the popular Fuchsia; the newer varieties greatly enhance its reputation, so much so that the majority of the older varieties are fast disappearing. I had occasion lately to visit quite a representative collection, and as the present is a suitable time to take cuttings I append a list of varieties which appeared most striking.

#### DOUBLE VARIETIES.

*A. Delaux*, grand purplish blue, splashed carmine.

*Alphonse Daudet*, rather short flower, heliotrope-lilac.

*Buffon*, a splendid giant white.

*Achilles*, fine rose, red sepals.

*Hector*, bright magenta.

*Graphie*, intense purple.

*Calliope*, huge purple striped.

*Erman*, purple singular reflexed petals.

*Manfred*, loose spreading heliotrope, excellent.

*Claudia*, magnificent pinky rose, one of the best.

*Mme. Carnot*, immense white, extra.

*Mrs. E. G. Hill*, exquisite creamy white.

#### SINGLE VARIETIES.

*Aurora superba*, sepals and petals salmon, orange corolla.

*Champion*, huge white, striped.

*Cameo*, large rose-purple.

*Elsa*, fine ruby-rose sepals and petals.

*Tribute*, bell-shaped, rich violet-purple.

*Lothair*, handsome, heliotrope colour, small flowers.

*Fascination*, palest rose, white sepals and petals.

*Fortuna*, rich rose, good form.

*Jason*, deepest crimson, grand colour.

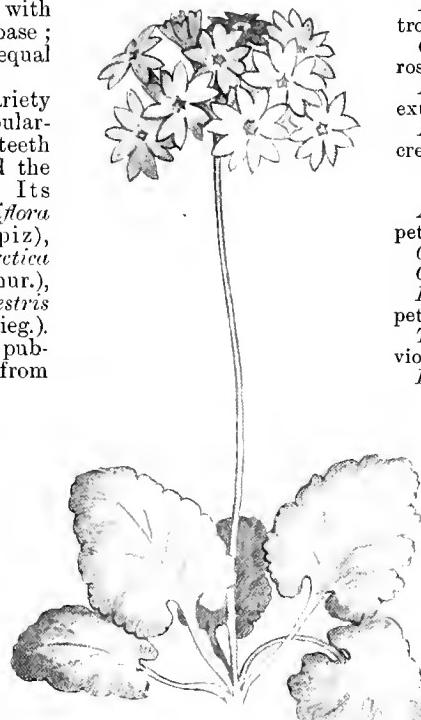

*Tulip*, small salmon flower, very useful.

*Professor Ruskin*, blackish purple, the best.

*Mr. H. Roberts*, an intense salmon-scarlet.

*Swanley Yellow*, a new variety quite in front of anything sent out in this shade.

To conclude, I may

PRIMULA CORTUSOIDES (REDUCED ONE-HALF).

of the finest form, and bold in the truss. This is a decided addition to the white zonals.

Mary Carmichael, warm orange-salmon, a very attractive shade of colour; fine in pip and truss.

Mary Hamilton, rich crimson scarlet with a distinct white eye; flowers large and of perfect form; one of the best.

Mary Seton is of a bright vermilion tint; on the upper petals is a large white blotch, suffused and margined with lake. This is said to be an extremely free-blooming variety.

It will be seen from the foregoing names that Messrs. Pearson and Sons have commemorated in the floricultural annals of the day the unfortunate four Marys, maids of honour to Mary Queen of Scots.

Three varieties distributed in 1890 by Messrs. H. Cannell and Sons, Swanley, were also seen in the collection in very fine character, viz.:—

Lady Laurier, clear salmon, with a large white eye; pip large, stout, and of fine form.

Mrs. Kendal Barnes, intense crimson, flushed with purple, pip large and finely formed; quite striking.

Winston Churchill, clear magenta-pink, with a well defined white centre, covering much more of the surface of the corolla than is usually seen.

Two new double zonals of the same year were seen in the collection: Golden Glory, one of the orange-tinted section, the flowers bright and striking, and of the best form; Mme. Carnot, pure white, producing its large well-formed flowers on bold trusses.

Some of the new double zonals of 1899 were also in the collection: I made a note of the following:—

Charles Gounod, large bright scarlet, white centre; an excellent variety.

Mme. Goyeux, soft rosy pink, white in the centre; pleasing and effective.

Mme. H. Thibaut, pale centre, margined with bright scarlet, large flower and truss.

M. J. B. Tarrone, white centre, heavily margined with scarlet, and having a shading of magenta, large truss.

Reine Baxin, soft salmon margin on an orange tinted centre; well formed flowers and fine trusses.

To the foregoing may be added one of 1900, Fraicheur, white centre with a narrow band of rose round each petal; distinct and pleasing.

These double zonals of 1899-1900 are all white, and known as the Mme. Jules Chretien type, having pale centres with a bedding or margin of some colour, a type that is being rapidly improved and coming into favour.

Of the new single zonals of 1899, six raised by Pearson and Son are very good:—

Barbara Hope, pale salmon-pink, with white eye; large and of fine form.

Cerise, clear cherry red, distinct in colour and well formed.

Florence Miskin, cerise-crimson, with light eye; extra fine.

Lilian Duff.—This is described by the raisers as "a magnificent crimson in the style of Herrick, but finer in size and form; the pips are 3 inches in diameter, the broad overlapping petals forming an almost perfect circle; a splendid novelty."

Mary Pelton, delicate soft salmon, of a very pleasing shade of colour; flowers large and of fine form.

Mrs. Charles Pearson, rich orange-salmon, with conspicuous white eye, described as "a flower of immense substance and perfect form, the most beautiful zonal in commerce."

Of Messrs. H. Cannell and Sons' distribution in 1899 three in particular struck me as very fine:—

Mrs. Fisher, soft satiny salmon of an attractive shade; large pips produced on bold trusses.

Snow Storm, large, stout, clear, pure fine pips on good trusses.

The Sirdar, a fine scarlet, large in size and of the best form; must become a popular variety.

Some very fine single zonals were among the batch of new varieties sent out in 1898, and of these Andrew Lang, scarlet, white blotches; Conan Doyle, clear salmon-pink; Hall Caine, bright cherry red; Ian Maclaren, deep shade of salmon,

becoming paler toward the edges; Mary E. Wilkins, pale, violet-pink, a pretty shade of colour; Mark Twain, white ground, freckled and flaked with carmine on the petal edges; Mrs. Ewing, pale salmon; and Rudyard Kipling, rich crimson-purple, were all raised by Messrs. Pearson and Sons. One fine variety came from Messrs. H. Cannell and Sons, viz., W. G. Gordon, rich clear scarlet, with white eye.

Some varieties of older date are well worthy a place in collections. Shades of scarlet and crimson: Chaucer, Crabbe, Dr. Macdonald, E. Bidwell, Herrick, J. H. Arderne, and Shelley; blush: Duchess of Marlborough; salmon: Magnificent, Mrs. D'ombra, and Midsummer; pink: Gertrude Pearson, pure rose pink; white: Eucharis. Then of the newer reticulated section, Dryden, bright rosy red, with large white blotches. A few of the finest double-flowered zonals of the same date are Mme. Laundry, deep salmon; Pasteur, brilliant rose, very large trusses; and Thomas Meehan, pale rosy lake, semi-double, forms enormous trusses.

In the collection could be seen some very fine double Ivy-leaved Pelargoniums, which are probably not so well known as they deserve to be, viz., Colonel Baden-Powell, deep mauve, very fine; Mrs. Hawley, bright cerise, shaded with rose, extra fine; Mrs. J. G. Day, crimson-scarlet, very bright; Leopard, lilac-pink, heavily blotched with crimson; Rose Queen, soft rosy pink; and Achievement, soft salmon-pink, very large semi-double.

R. DEAN.

## NURSERY GARDENS.

### CHINA ASTERS AND ANTIRRHINUMS.

#### NOTES MADE AT MESSRS. SUTTON AND SONS.

VISIT to Messrs. Sutton's grounds is always a wholesome reminder of the wonderful wealth of annual plants that is at our disposal. A special visit on August 9, for the purpose of observing the progress that has of late years been made in the China Aster, showed the wonderful variety that has been achieved in the many classes of this popular autumn flower.

To describe even a tenth part of the flowers on view would be a lengthy task, but the object of the visit being in the first place to note the very cream of the collection from the point of view of the amateur with a refined colour-eye, it comes within manageable bounds.

There can be no doubt that as beautiful plants bearing beautiful flowers the first to be mentioned must be the comparatively new Comet and Ostrich Plume sections, and among these the pure whites and the dainty pinks and lilacs stand out conspicuously for charm and refinement. Among the Comet class may be mentioned for remarkable beauty Giant Comet Peach-blossom, a tender salmon-pink, just the kind of colour that has so long been wanted, and Blushing Beauty, another dainty colour inclining to mauve-pink. These two, though both lovely, should not be placed together, but both are good with one of the fine whites, such as the white Giant Comet of their own class.

A beautiful flower is Light Blue, the colour being really a very pure and silvery tone of lightest lavender. This one harmonises delightfully with another known as white passing to azure blue, of a slightly deeper lavender-lilac. Blue Comet is also a very fine thing. There is also among the Comets a pretty new colouring, a clear lemon-white, known as Comet, light yellow. A good new colouring among the medium-sized Comets is a coppery rose called Meteor.

#### PRIMULA DENTICULATA (REDUCED).

(See preceding page.)

remark that the autumn propagation of Fuchsias ought to be more generally practised. Almost any shoots will readily root at the present time. They may be inserted several in a pot, or singly, a close frame being an admirable position for them.

Carefully water, and when rooted pot singly in a moderately light compost. During the winter avoid strong heat, a greenhouse temperature not exceeding 45° I have always found suitable. In such a temperature a stout growth is the result, and if the points are taken out good plants ready for potting on are easily secured.

A. B.

#### ZONAL PELARGONIUMS AT TAUNTON.

ONE of many features of interest at the recent Taunton Floral Fête was a collection of cut blooms of zonal Pelargoniums exhibited by Mr. Vincent Slade, nurseryman, of that town. They were admirably set up in distinct bunches of one variety, the flowers were fresh and of fine quality, and the collection proved a great attraction for the visitors. Among them were several of Pearson and Sons' new varieties of 1900. Such as

Mary Beton, a very fine pure white variety,

The Ostrich Plume Asters may for all ordinary garden purposes be classed and described with the Comets. They are of nearly the same free habit, and are breaking into the same good range of colourings. Another fine flower in the larger growing, free branching Asters, which are the kinds most sought for by amateurs of taste, is Empress Frederick, a large white flower of the Comet type, but the kind is hardly as yet fixed, a good number not coming true.

The fine single purple Aster sinensis was only beginning to show flower; it is a plant for the second half of September. With it should be grown the vigorous, long-stemmed Vick's white, a tall, branching kind, grand for cutting, and a fine garden plant. Of this Messrs. Sutton have a good new break in a beautiful blush variety which they know as Mammoth Aster, shell pink.

Among the shorter growing Asters some of the best are in the class known as Paeony Perfection, of the shape formerly known as Truffants. The variety called Azure Blue is excellent; its colour is that clear silvery lavender-lilac that is always one of the best of the Aster colourings. In this section is a striking flower of very deep but splendid colour, exactly described by its name Blackish Purple. In the smaller types of this section there is also a beautiful blue.

The Triumph section contains excellent flowers and beautiful colourings, in which the so-called scarlets, of a fine rosy-blood colour, are conspicuous. This grand colouring, since its welcome introduction, has been specially brought forward by Messrs. Sutton, and, among the hard pinks and garish magentas to which Asters are so naturally prone, it is a departure that cannot be too warmly appreciated by those who love beautiful colouring. Among the Triumphs is one called Royal Purple of an unusual rich ripe mulberry colour.

A large proportion of the trial ground devoted to Asters is still given to the dwarf bedding classes. Among these, one called Bright Rose is of a beautiful tone of colour. Still smaller in growth are the dwarf bouquet kinds, among which the best colours, other than white, are the scarlet, purple, and dark blue. Little Gem is a class for pots, of small, compact habit, not over 10 inches high.

Among the Crown or Cockade Asters are many pretty flowers, notably lilac and white, and among the miniature, crown-flowered series a remarkably bright flower, scarlet and white, called Jewel.

There are still many amateurs who, knowing only the China Asters of some years ago, of stiff shape and hard or unpleasant colouring, say they do not like Asters, and it is not infrequent to find that gardeners are forbidden to grow them. If this should meet the eye of any of these, I venture to think that a welcome surprise awaits them if they will give a trial to the kinds named in the foregoing notes.

It is very striking in these grounds to see the extreme cleanliness of the stocks. There is a good half acre, perhaps more, of Asters, in many hundreds of varieties, and it is the

rarest thing to see a rogue. When one knows that it takes years of work to "fix" a variety it is a sight that inspires a feeling of very comfortable confidence in and admiration for the unsparing care and patience that our growers of the highest rank devote to their stocks before they are offered to the public.

A great advance is also to be seen in Messrs. Sutton's grounds in Antirrhinums, the old favourite Snapdragons of our gardens. They are in three divisions—tall, intermediate, and dwarf.

Among the tall kinds are two of singular beauty—Coral Red, a beautiful tint of full rosy pink, with white tube, and Carnine, a deeper, whole-tinted flower in the same kind of colouring, not yet in commerce; Cloth of Gold, a splendid yellow; Pure White, and a flower of refined beauty called Rosy Morn, white, flushed with tender pink, with a yellow

heavily fringed margin; the colour a pleasing and delicate shade of rose-pink. It is doubtful if any have surpassed this beautiful hybrid among the number that have since been introduced. Derived from the intercrossing of *L. digbyana* and *C. Mossiae*.

*Lelia digbyano-purpurata*.—This was raised by Mr. J. Seden in Messrs. J. Veitch and Sons' nurseries from the parentage indicated in the name. It has proved one of the most variable, both in colour and the character of the flowers. In some cases the lip has been short and no fringe apparent on the outer edges of the front lobe, whereas extreme fringes and elongated front lobes have appeared, as in the variety King Edward VII. It has a good constitution, and thrives well under Cattleya house treatment.

*L.-C. digbyano-Trianae*.—Raised in Messrs. J. Veitch and Sons' nurseries from the parentage indicated in the name. It is one of the most delicate rose-tinted varieties of the section.

*L.-C. Thorntonii* (*digbyana* × *gaskelliana*) is a most desirable variety, with free habit and pale rose-tinted flowers. It first flowered in Mr. T. W. Thornton's garden, at Weedoo, in 1897.

*L.-C. digbyano-Mendelii* was raised by M. Maron, of Brunoy, France. It was exhibited at the Royal Horticultural Society's meeting on March 14, 1899, as *L.-C. Imperatrice de Russie*, and will be found described under that name in THE GARDEN report of the above-mentioned meeting. It is not so fine as most of those previously mentioned, but its delicate shade of colour is most attractive.

*L.-C. Mine. Chas. Maron* was also raised by M. Maron from the intercrossing of *C. Warscewiczii* and *L. digbyana*. From such a fine parent as *C. Warscewiczii* one would have expected a much finer offspring than that exhibited at the Royal Horticultural Society's meeting on September 24, 1901. It is larger than most of the section, but it is wanting in substance and colour and is a disappointment.

*Lelia Mrs. M. Gratrie* is one of the most distinct, and is exceedingly variable. It was raised by Mr. J. Seden between *L. cinnabarinia* and *L. digbyana*. The orange-red which predominates in all hybrids derived from the influence of *L. cinnabarinia* is most prominent

here, rendering it one of the most distinct and desirable of the section.

*L.-C. Edgar Wigan*.—The subject of the accompanying illustration was exhibited at the Temple show, 1901. It is derived from *L.-C. Aphrodite* and *L. digbyana*. The first-named parent is itself a hybrid between *C. Mendelii* and *L. purpurata*. It is one of the most beautiful of the section, and embraces many of the qualities of *L. digbyana*, the heavily fringed front lobe of the labellum being most prominent; the colouring of the lip rosy pink, shading to delicate lilac, with some sulphur-yellow in the throat.

*Lelia Helen* (*tenebrosa* × *digbyana*).—Raised by Messrs. J. Charlesworth, Heaton, Bradford, and was exhibited at the last Temple show. The bronzy suffusion infused through the influence of *L. tenebrosa* renders it most distinct and attractive. Like most other hybrids derived from *L. tenebrosa*, it will no doubt improve as the plants gain strength.

H. J. CHAPMAN.

Oakwood, Wylam-on-Tyne.

LELIA-CATTLEYA EDGAR WIGAN (MUCH REDUCED), ONE OF THE MOST BEAUTIFUL OF THE HYBRIDS.

lip. The scarlets and deep crimsons, yellows and whites are also excellent in all the sections.

G. J.

## ORCHIDS.

### LAELIA (BRASSAVOLA) DIGBYANA HYBRIDS.

ONE of the Cattleya family are more popular at the present time than the hybrids that are due to the influence of *Lelia* (*Brassavola*) *digbyana* as one of the parents. Delicate colouring is a characteristic feature of this now somewhat large section of hybrids. The chief complaint that can be urged against them is that the flowers do not last many days in perfection after they have fully expanded, but as the whole section of these hybrids possess robust constitutions and rarely fail to flower satisfactorily when once they have reached the flowering stage, they deserve extensive cultivation. The following is a brief summary of the different hybrids that have flowered to date:

*Lelia-Cattleya digbyano-Mossiae*.—This hybrid first flowered in May, 1879. It is a flower of fine shape, the lip being very broad and with a

### RECENT PLANT PORTRAITS.

The fourth part of the seventh volume of *Lindenia* contains portraits of the following four Orchids:—

*Dendrobium nobile* var. *Jaspideum*.—This is a very handsome and deeply coloured form of this well-known Orchid, most of the petals being mottled

with a deeper shade of colour than their ground, and with a fine clearly defined white ring round their centre.

*Odontoglossum - Adriana var. leopardinum*.—This is one of the crispum section of the family with medium-sized white flowers, heavily spotted with rather dull brown.

*Habenaria medusa*, a curious variety with deeply serrated flowers of the purest white.

*Lathia Cattleya* var. *Pauli*.—This is a delicately beautiful variety with medium-sized flowers and handsome deep rosy purple lip.

The second part of the *Revue Horticole* for September figures a group of small and insignificant flowered Cinerarias named *hybrida polyantha* with apparently nothing whatever to recommend them.

W. E. GUMBLETON.

## THE FRUIT GARDEN.

### PYRAMID PEAR TREES.

FEW fruit trees are more profitable than the pyramid Pear, and for this reason—they require less space than standards, do not interfere with other crops, and are more easily attended to. For gardens restricted in size I would certainly recommend trees grown thus. Some varieties are more suitable for pyramid training than others. A few of the Pears grow very strongly, and later I will note a few of our best varieties grown in this form. Of course even with pyramid trees there must be proper pruning, or, what is better, stopping the shoots when

young. Where this is well carried out much wood that does harm in crowding the inner portion of the trees may be removed. I have heard some growers condemn this method of culture as being unnatural, but a great deal depends upon culture. This season, however, our best cropping trees are the pyramid Pears, others with more freedom of growth have very few fruits. It is surprising what splendid fruit pyramid Pears will produce when given the necessary attention and manuring; the latter, I fear, is often overlooked.

With pyramid Pear trees root pruning in the early autumn should not be forgotten. This is more necessary with young trees, say from three to ten years old. I need not go into the system of root pruning necessary to promote a fruitful growth; it is frequently touched upon in these pages, and is very simple. A great deal depends upon the age of the trees, and with young gross trees in many cases lifting would be preferable to pruning. As regards planting, if ample room can be given between the trees it is much better for the ripening of the fruit—there is nothing gained by crowding—but if the trees are grown on the Quince stock the growth is less vigorous and less space is needed. Most of the pyramid Pears do best on this stock; there is only a limited number that are best on the free or Pear stock. For amateurs pyramid fruit trees have a special claim. Trees two or three years old begin fruiting at once, and though the crop at the start may not be large the fruits are good, and each year increase in quantity; when planted alongside the garden walks they do not unduly shade vegetable crops, and are easily reached when requiring attention.

The following are the best varieties for pyramids. I have omitted the very early kinds, such as Doyenné d'Eté and Jargonelle, Clapp's Favourite, and Williams' Bon Chrétien.

There can be no question but that the large fruiting varieties, as Pitmaston Duchesse, are far better grown as pyramids than in any other form, for then the heavy fruits are protected from high winds. Another important point with pyramid fruit trees is their protection from high winds and frost when in sheltered gardens. One of the best varieties is undoubtedly Louise Bonne of Jersey; it is a sure cropper and a delicious fruit. The tree is shapely, not a gross grower, and it is not fastidious as to soil or situation. On a light soil Souvenir du Congrès, a very good September Pear, does well as a pyramid, but here it thrives on the Quince stock, but needs double grafting. The fruit is very juicy and melting, and is a great favourite when it succeeds. The newer Dr. Jules Guyot should be in all gardens; for an early supply this is not unlike the last-named, but hardier and a compact grower on the Quince, and, what is better, it bears profusely and regularly. Though it does not keep long it is a very handsome fruit. Beurré Mor-

tillet, also a late September fruit, a recent introduction, is a valuable pyramid Pear. This year it has borne grandly, whereas old trees on walls have very few fruits; it does best on the free stock or double grafted. Another new Pear that has never failed to crop since it was planted is Rivers' Conference, a large, long, handsome, well-flavoured fruit with deep green skin, the flesh when ripe pink coloured; it keeps well into November. This is a valuable pyramid Pear for gardens where only a few varieties are grown, for it is remarkably prolific.

I now come to the October Pears, and here we have the best quality, and many of them do well in pyramid form. Louise Bonne should have a good place in the list for the month named. Another very fine cropper is Durondeau. It cannot be compared as regards quality to such kinds as Marie Louise or the beautiful Doyenné du Comice, but I advise its culture for its heavy cropping, its shape, and colour, and in some soils the flavour is not inferior. Next on the list is the valuable Marie Louise, which is good in well-drained soils. Marie Louise d'Uccle does well in heavy soil. The Queen of Pears, Doyenné du Comice, does grandly as a pyramid. This should be largely grown; it has no equal as regards flavour, and, though it is not so free cropping as some kinds, if several trees are grown in different parts of the garden a better result is secured. Pitmaston Duchesse I have referred to as good for a pyramid. Thompson's also is good, and Emile d'Heyst, a pretty Pear, is very prolific. Beurré Diel and Beurré Fouqueray are both excellent, and space should be given to such excellent keeping kinds as Nouvelle Fulvie, Josephine de Malines, and Marie Benoist. These latter do grandly grown thus for late supplies.

G. WYTHES.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

## HERETICAL SENTIMENTS.

[To THE EDITOR OF "THE GARDEN."]

SIR,—I must confess to feeling considerable sympathy with "R. H. W." and as nobody else has expressed any he may think mine worth accepting. No one admires glorious colour effects more than

I do, but it is, I think, useless to lay down this kind of gardening as the only way, for there are certainly more people who are not able to compass it in their gardens than lucky souls who have space and labour—leaving money aside, though it is essential—to make a chief end and aim of broad effect. In all gardens of any importance there is also the kitchen garden. Massing flowers would be impossible here, and it would be a pity to be content with massing Cabbages, hence there are very likely some hundreds of yards of edging and border where spotty planting—to give it its crudest name—of flowers is surely preferable to having no flowers at all. Personally, I think those old-fashioned kitchen gardens, where the vegetables are in squares with flowers round all the edges some 3 feet inwards from the paths, are delightful. Probably the plants in such a place have been put in without much planning beforehand, but although we may find a clump of flaming scarlet Salviæ next to a group of *Delphinium Belladonna*, or late pink Roses against purple Asters, a walk round is full of individual interest, and the plants seem more friendly than where they are grouped by the hundred for distant effect. A necklace of diamonds is a beautiful possession, but those who cannot afford it, and even some of those who can, may like to possess a collar of that deep Indian gold, much worked and set with many-coloured jewels of all sorts and sizes. In a garden where there are magnificent masses of Peonies, Tulips, and every sort of grand effect we may yet find pleasure, for a change, in visiting the mixed "supply" border,

PYRAMID PEAR TREES (LOUISE BONNE OF JERSEY) IN THE R.H.S. GARDENS.

where we can get sharp contrasts and see all-round things.

I do not see that because a border is planted in mixture that it is necessarily "crowded." Each plant or group of plants may have quite as much room as if its next door neighbours on both sides were of exactly the same pattern. Is it not one way to discontent the smaller cultivator with his possibilities if we insist so strongly upon massing, everywhere, and in all cases? For, done in such gardens as even wealthy folk must put up with if they live in or near towns, massing is often not a success. As an instance I may cite a walled square I saw not long ago where the whole length of four 5-feet wide borders was filled with red herbaceous Phloxes. The effect—there was a colour effect!—was simply one of extreme monotony, and I think, in this case, group planting, even in threes, of a variety of different plants would have been infinitely preferable and given much more pleasure and interest for a much longer season. I hope some other readers will give their opinions, for as a rule it is the owner of the moderate or ordinary garden, from one to five acres might perhaps be a fair limit, who most needs teaching, and is most eager for it. One wants to make the best of the ground available, and where it is but a small space to consider how it shall be made most interesting. I am inclined that for moderate gardens there is most pleasure and interest in an arrangement like that of the Bath Botanical Gardens—plenty of individualising, and some grouping, and some massing, but no preponderance of either. These gardens are really not "spotty," yet there is a constant succession of varied colour, and plants in singles and trios are very frequent, while all the year round there is some fresh interest, which would be lacking if there were one-fourth or less of the plants in broader masses of each.

M. L. W.

#### BAMBOOS IN INDIA.

[To THE EDITOR OF "THE GARDEN."]

SIR,—In THE GARDEN of July 19 it is stated that owing to exposure to cold winds of March and April the hardy Bamboos grown in England drop their foliage after having withstood severe frost in winter. Bamboos grow in this country between elevations of 100 feet to 12,000 feet, and as a rule they drop their leaves in March and April, not on account of cold wind, but because it is the Indian spring, when the majority of trees drop their leaves and almost immediately afterwards burst out into fresh foliage. Is it not possible that the Bamboo in England is simply following what it used to do in the East?

Darjeeling, India.

G. L. S.

#### PERENNIALS AND ANNUALS FOR BORDER.

[To THE EDITOR OF "THE GARDEN."]

SIR,—Could you please kindly favour me through your valuable paper with a list of flowering and showy perennial plants most suitable for a border exposed to the sun. Height for back to be about 5 feet or 6 feet, sloping to the front to about 2 feet or 18 inches. The soil is rather stiff, with grand old Magnolias on a wall behind. J. C.

[For the spring, which we may consider as extending to the first day of June, the following and handsome perennials: *Doronicum plantaginaceum excelsum* Harpur Crewe, which often commences to expand its large golden stars in March, the Lyre Flower (*Dicentra spectabilis*), both about 3 feet in height; herbaceous Peonies that flower at the end of May, around which may be planted the stronger golden Trumpet Daffodils, such as Maximus, Emperor, and Golden Spur, whose rich yellow associates well with the young carmine shoots of the Peonies; *Achillea Ptarmica fl. pl.* The Pearl generally begins to flower in May, growing to a height of between 2 feet and 3 feet, and extending its blooming season until the autumn.

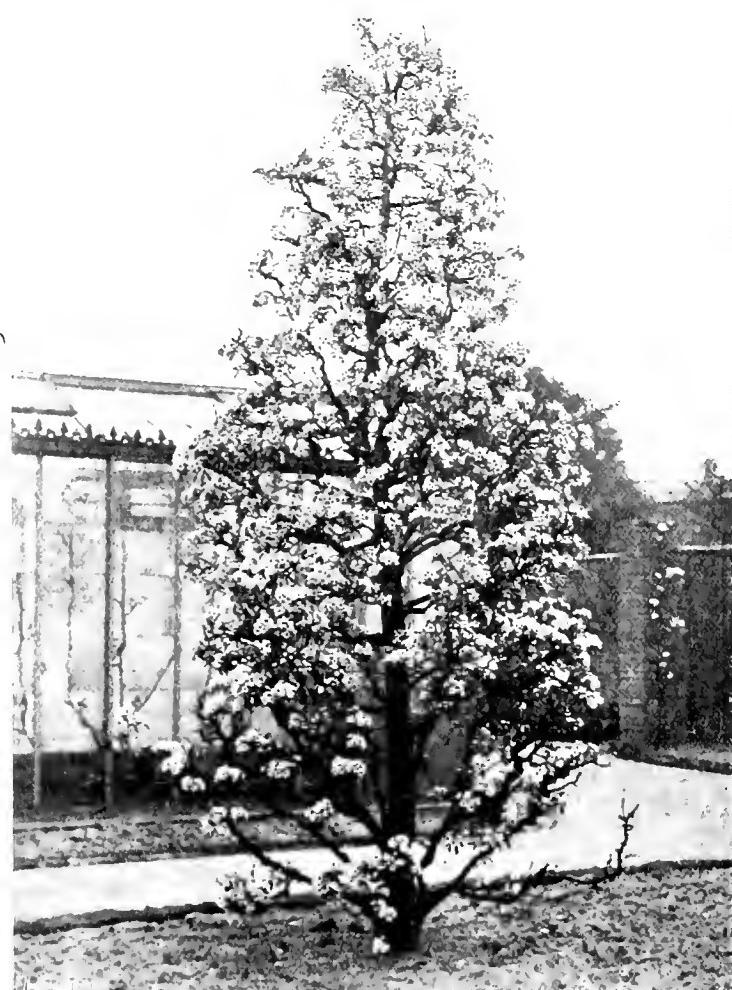

Masses of May-blooming Tulips are very effective in the border, especially highly-coloured sorts, such as *gesneriana major*. At the close of May

the giant Oriental Poppy provides a blaze of vermillion, and the German Irises disclose their manifold tints. Good varieties are Princess of Wales, white; aurea, golden-yellow; flavescens, light yellow; atropurpurea, deep purple; Bridesmaid, white and blue; Mme. Chereau, white and lavender; Victorine, white and violet; Queen of the May, rosy lilac; and pallida, lavender.

Of summer-flowering perennials there is a large selection, of which the following list contains some of the best: For the back of the border, Hollyhocks, the Plume Poppy (*Bocconia cordata*), Delphiniums, and *Rudbeckia laciniata* Golden Glow, the latter an August bloomer, each of which with good culture will attain a height of 7 feet or 8 feet. Of plants of less commanding stature we have *Alstroemerias*, the hybrid *A. chinensis* being the most ornamental, height 3 feet; the taller *Campanulas*, of which the newer forms of *C. persicifolia*, namely, *C. p. Moerheimi*, white, semi-double, and Backhouse's variety, single white with very large flowers, are particularly fine; *C. grandis alba*, *C. lactiflora* and its white form; *C. latifolia*, and the Chimney Campanula (*C. pyramidalis*) for August flowering. *Chrysogonum virginianum* is a pretty plant,

growing 18 inches in height and bearing yellow flowers through many weeks; and *Erigeron (Stenactis) speciosum* has an even more extended blooming period, often holding its lavender, yellow-centred star flowers into October and growing to a height of 4 feet. The Globe Thistles and Sea Hollies are valuable for their metallic blue flowers; of the former *Echinops ritro* is one of the best, and of the latter *Eryngium oliverianum* and *E. amethystinum* are the most handsome species. The latter rarely exceeds 2 feet in height, but the two first-named often reach 4 feet. Of Day Lilies the clear yellow *Hemerocallis flava* (18 inches) and the large orange *H. aurantiaca major* (3 feet) are the best. *Galega officinalis alba* is a handsome plant, forming a large bush covered in the summer with white Pea-like blossoms, height 4 feet.

The Cape Hyacinth (*Galtonia candicans*) is a bulb that has a telling effect in the border when planted in large groups. Its pyramidal heads of drooping white bells, with good culture, reach a height of 5 feet. *Inula glandulosa* bears large, flat star flowers of bright orange, and is 3 feet or more in height under favourable conditions. Two fine summer-flowering Irises are *I. orientalis*, or *ochroleuca*, white and yellow, and *I. Monnierii*, golden, both 5 feet in height. *Libertia grandiflora* produces an abundance of white flower-spikes 3 feet to 4 feet high. Of the Evening Primroses the tall *Oenothera lamarckiana* (5 feet or more in height) and *O. fruticosa* or *Youngii* (3 feet) are good border flowers, as are *Ornithogalum pyramidale* and *Camassia Leitchlini*, white

PYRAMID PEAR TREE (BEURRE DIEL) IN THE R.H.S. GARDENS, CHISWICK.

and pale yellow respectively, 3 feet in height. Herbaceous Phloxes of good colour add much to the brightness of the border, and under careful cultivation attain a height of 3 feet or more. Good varieties are Mrs. E. H. Jenkins, white, with carmine eye; *Platycodon grandiflorum* and its white variety, plants bearing large purple and white flowers, 2 feet in height; the old double white Rocket, a charming subject growing 2 feet or more in height and producing long trusses of fragrant flowers; *Scabiosa caucasica* (2 feet), large pale blue flowers, there is also a white form of this; and *Sidalcea Listeri*, a beautiful plant, 3 feet, bearing long spikes of flesh-pink flowers. Many Lilies are admirably adapted for the embellishment of the herbaceous border. Of these the fairest is the favourite Madonna Lily (*L. candidum*). Other species of easy culture are *L. elegans* or *thunbergianum* and *L. umbellatum* in their many named varieties, *L. croceum*, *L. excelsum* or *testaceum*, the Martagon Lily and its white variety, the scarlet Turk's-cap (*L. chalcedonicum*), and the Tiger Lilies, of which the best are *L. tigrinum splendens* and *L. t. Fortunei*.

In the autumn *Anemone japonica alba* bears its white flowers after growing to a height of 4 feet. The Michaelmas Daisies or perennial Asters are a large family indispensable in the autumn garden. Of these the following are good: *A. Amellus* bessarabicus, 3 feet, early, with large, violet-blue flowers; *A. ericoides*, 2 feet 6 inches, with countless tiny white blossoms; *A. cordifolius* and its

varieties, 4 feet : A. Robert Parker, lavender, and A. Purity, white, 6 feet : A. acris, violet, 3 feet ; A. patens, blue, 2 feet ; and A. Archer Hind, purple, 4 feet. Chrysanthemum maximum bears large white Daisy-like flowers. The ordinary form grows 4 feet in height, but the newer and more floriferous variety rarely exceeds 2 feet. Perennial Sunflowers are best known by the varieties Helianthus multiflorus and its double form Soliel d'Or, 4 feet ; but H. rigidus Miss Mellish and H. latiflorus, 6 feet, bear finer flowers. Pyrethrum uliginosum is a graceful plant, 5 feet in height, bearing large narrow-rayed white Daisy-like flowers.

In the winter the Algerian Irises (*I. stylosa* and its white form) and Christmas Roses will prevent the border from being flowerless. Care should be taken in planting that the flowers shall not give a formal effect. Lines, circles, squares, and such-like figures should be rigidly avoided and the different species planted in informal groups. Colours that do not harmonise must be kept apart, and an endeavour should be made to lead up to the brightest tones by a succession of graduated tints. Though the tallest plants should, as a rule, be relegated to the back of the border and the dwarfer forms to the front, this arrangement should not be carried out throughout its entire length or the effect will be stiff and monotonous. Here and there tall plants should be brought forward, and in certain places dwarf plants should run to the back of the border, such disposition of the contents affording that charm of informality which captivates the artistic eye.—ED.]

## GARDENING OF THE WEEK.

### THE FRUIT GARDEN.

#### STRAWBERRIES.

**N**EW plantations that were made as soon as the runners were sufficiently rooted having now made satisfactory root progress, will be greatly benefited by a thorough watering with liquid manure when the soil is sufficiently dry. We have followed up this practice for many years, and have found it greatly strengthens the plants, but the manure must be applied while growth is still active. This treatment is particularly to be recommended for young plants cultivated for early fruit or for producing early runners for layering. Older plantations also derive benefit from this mode of treatment. Failing liquid manure a dressing of soot and bone-meal should be given. Keep the plants free from runners and the soil between them quite clean. Protect alpine varieties from birds, and keep the plantations clean.

#### ROOT PRUNING AND LIFTING.

A diversity of opinion is held respecting the utility of this work, but it must be remembered that circumstances which govern the desirability or otherwise of carrying it into effect are not always taken into account, hence the conflict of views held. Trees, however, that are unfruitful owing to exuberant growth may often be made fruitful by being properly root pruned, &c. Attacks of canker when caused through the roots having penetrated into ungenial subsoils may also be cured or at least diminished by this treatment. It is advisable to make the work extend over two years by pruning the roots on one side only of a tree in a season. The best time to do this work is in early autumn. When the object is to lift the roots out of unsuitable subsoils an opening should be made near their points sufficiently deep to reach the lower ones, and the soil carefully worked from amongst them until they are liberated, when the opening should be refilled, and if necessary with fresh soil, mixed with suitable ingredients, such as bone-meal, wood ashes, mortar rubble, &c. First fill the vacant space to within 2 feet of the top, and then, as the filling proceeds, regularly relay the roots amongst the soil to within 6 inches of its surface, making the soil quite firm. In

dealing with trees that are unsatisfactory owing to having made strong unfruitful wood, a trench should be made, according to the size of the tree, from 3 feet to 6 feet from the stem, working beneath the tree, and severing any tap roots to be found. Make the ends of the roots perfectly smooth by a clean upward cut, and lift the roots nearer to the surface of the soil. Treatment of this description usually promotes fertility the second year after root pruning.

T. COOMBER.

*The Hendre Gardens, Monmouth.*

### THE INDOOR GARDEN.

THE earliest Persian Cyclamen are now coming into flower, and will make a fine display throughout the autumn months. They should now be moved from the cold frames into a well ventilated structure and afforded a little fire-heat. Care should be taken to keep them absolutely clean. The least check now will tell against them when they come into bloom. Shading, too, must be discontinued. Ericas should now be placed in a light and airy house. Fire-heat should never be applied except to keep out frost or damp. Destroy mildew by dusting the affected parts with flowers of sulphur. Water with care.

#### TREE CARNATIONS.

These should be moved to a light and airy structure. Fumigate with XL All occasionally to keep thrips and green fly in check. Plenty of air should be given on all occasions while the weather is favourable. Poinsettias will not bear cool treatment any longer ; a low temperature now will soon cause the lower leaves to fall. Plenty of light and a moderately warm atmosphere should be given them. Manure frequently.

#### COLEUS THYSOIDEUS.

Discontinue stopping the shoots of this useful winter-flowering plant, so as to allow them to produce flowers. The plants should be placed in a light position and kept near the glass in order to keep them strong and short jointed. The temperature most suitable for this Coleus in winter is one ranging from 60° to 65°, according to the state of the weather.

#### VIOLETS.

should be removed and planted in frames or pits facing south, choosing a sheltered position if possible. Some rough material should be placed at the bottom of the frames, so that when about 9 inches of soil is put in the plants will be a foot or so from the glass. Soil from old Melon and Cucumber beds will make a good compost. Water well after planting, and shade for a few days. The lights are better left off until signs of frost appear. Violets can also be successfully grown in pots. Plants for this purpose should be placed in 6-inch pots, choosing the strongest plants and letting them remain outside as long as possible. After housing place them in a light position, giving plenty of air.

JOHN FLEMING.

*Wexham Park Gardens, Slough.*

### THE KITCHEN GARDEN.

#### MAKING A NEW GARDEN.

SEPTEMBER is a capital month for preparing the land which is intended to do duty as a kitchen garden, either by making additions or creating new ones. Much will depend on the after-success as to the way it is treated in the first instance. Choose, if possible, a piece of old pasture land that is well sheltered from the north and east winds. Though it does not often fall to the lot of the gardener to pick and choose the site, it is nevertheless of great importance that a good one should be selected if good crops of vegetables at all seasons of the year are desired, and also hardy fruits are to be produced. It should also be taken into consideration that generally speaking a kitchen garden after once it is made is expected to do duty for many years to come, and when well and systematically managed there is no reason why it should not.

After deciding on the arrangements as to the walk and plots, a proper system of draining should

be thoroughly carried out. Four-inch agricultural pipes should be used for the purpose, and these should be placed not less than 3 feet 6 inches, or better still 4 feet, to allow for deep trenching. The walks also should be well made and ample provision allowed for carrying off the water, and a good durable edging, such as blue Staffordshire tiles, securely fixed in concrete, should be arranged. This is far better than turf, Box, or any other live edgings, as it entails much less labour, as these require no upkeep, and the paths are easily kept free from weeds without doing any damage by using weed killer, a matter of no small importance.

Trenching should then be proceeded with, beginning at the lowest end of the plot should the land be level, but if on the incline begin at the highest point, carting away sufficient soil to the spot where it is intended to finish. Allow plenty of room for working. Do not hesitate to go down quite 3 feet or 3 feet 6 inches, and work in plenty of manure from the farmyard, and any kind of garden refuse may be buried in at the bottom as the work proceeds. Bring up the lower spit to the surface. No attempt should be made to break it to pieces, but leave this for the weather. After the trenching is completed give a thorough dressing of soot, wood ashes, and lime, and should the ground be stiff add plenty of road scrapings, old mortar rubble, and such like, and should there be an absence of lime in the ground a good dressing of chalk will be most beneficial. If left in this state till early spring, and then again dug over, it should be in splendid condition for growing next season's crops of all kinds.

This is also the best season for renovating plots in old gardens which have been occupied with bush fruits, Strawberries, and the like for some years. Everything in the way of rubbish should be burnt on the spot, a good dressing of long farm-yard manure applied, and the ground thoroughly trenched, after which give a good surface dressing of lime and wood ashes. Add about 2 inches or 3 inches of fresh fibrous soil, good loam for choice. This should be left till March and then forked in, after which any vegetable crop should do well.

#### GENERAL WORK.

As most plots in the garden will now be occupied with growing crops, hoeing, thinning, and weeding will have to be attended to. Make further sowings of Turnips, Spinach, Lettuce, Endive, and Cauliflowers, and should the weather continue open these will prove serviceable next spring.

E. BECKETT.

*Aldenham House Gardens, Elstree, Herts.*

### THE FLOWER GARDEN.

THE propagation of flowering plants for another year should have commenced in the middle of August, but circumstances sometimes do not allow of destroying the beauty of beds and borders so early in the season, as taking up roots and cuttings necessarily does to a more or less extent, and it is often delayed until the present for that reason. Now, however, no time should be lost in pressing on with the work. Geraniums and Mesembryanthemums might easily have been struck in the open in August, but now they require the hot airy atmosphere of a propagating house or frame. Shallow boxes with a minimum of light sandy soil in which to strike, with very little water, are the best conditions for Geraniums ; moisture on the surface of the soil is conducive to damping off. Now is a good time to

#### PROPAGATE THE GAZANIA.

If the cuttings are inserted at once they strike freely in a cold frame, but if delayed they will require bottom heat. It is not much use potting up old plants, as spring-struck plants are worthless ; so the best plan is to propagate now in boxes and leave them in cold frames, protecting them only from frost. In the spring they can be planted out and will flower early in May. If coddled up in warm pits they make poor weak growth not worth planting out, but cold treatment gives short healthy plants. *Gazania splendens*, I find, is the best variety.

The present is a good time to put in Ageratum, Tropaeolum, Petunias, Salvia, and other similar

#### HALF-HARDY PLANTS

in cold frames, shading them from strong sunshine. Verbenas require a little special treatment. It is impossible to succeed with Verbenas when the wood is hard or when it is only flowering wood that can be obtained, therefore it is advisable to wait a little until the growth becomes succulent, which it generally does in the middle of October. Then put the cuttings in thickly in small pots and place them near the glass in bottom heat. It is almost impossible to keep old plants over the winter. Alternantheras, Coleus, and Iresines require heat for quick propagation. Now is an excellent time to put in cuttings of all the Violas, which in some localities may be put in at the foot of walls or in sheltered positions, but the best place of course is in cold frames, where they can be protected when necessary.

St. Fagans.

HUGH A. PETTIGREW.

### TO TOWN IN JAMAICA.

TOWN is Kingston. It is seventeen miles away. I have tea (breakfast) by lamplight, and am ready to start just as the east is reddening and the nightly chorus of insects is giving place to the twittering of wakening birds. It is about five o'clock, and I saunter off in the leisurely fashion of this land where business has not degenerated into slavery. It is between the night and day breezes, and there is only a light draught down the river, which I follow for a mile. The next three miles are steadily uphill to Guava Ridge (2,666 feet). At Mavis Bank, half-way up, are two Flamboyant trees (*Poinciana regia*) in perfection of beauty, a foretaste of what is coming. For to-day is the 7th of July, and this glory of the tropics is now at its best. It is a wonderful tree; the scarlet bunches of flowers exquisite in colour lie over it in broad masses, not evenly disposed, but here thicker and there thinner. This disposition gives additional value to the leaves delicately shaped, after the manner of an Acacia, and of a lovely pale green; and the tree, which is of forest size when full grown, is always shapely. It puts all its perfection together for this month of July, for truth compels me to say that it has ragged seasons when the leaves look battered and worn, and long unsightly brown seed-pods hung from the branches.

With eyes filled with the colour I walk on, hardly looking at the familiar path of pleasant low-toned yellow with its edging of Ferns. The Hibiscus hedges are fully out, but bright as they seem at ordinary times they look dull after the Poinciana. Passing through the scattered hamlet, where each house stands in its piece of cultivated ground, hidden away behind Mangoes, Jacks, and Oranges, under which grow Coffee and an occasional Chocolate, I turn to look back at the great range of the Blue Mountains, clear this morning from top to bottom. Then the path crosses the Falls River by a couple of bridges in quick succession, and following the narrow valley, which gets continually steeper, there is no more looking out till Guava Ridge is reached.

From here there is a splendid distant view over broken hills and plains heavy with the morning mist, and beyond these hills again range beyond range. The next four miles are steeply down. In the course of them we have to descend 1,600 feet or more. We are soon swallowed up in the valley following the new little river downward just as we follow the Falls River upward. There is the same Fern-edged path, the same tangle of bush with Mangoes conspicuous among the wild things, and clearings here and there for provision grounds. This is the greenest time of year, trees in full leafage and Yams twining up their sticks and looking their freshest.

I am well on my way, and the sun has not reached me yet. I see it on the hill tops, but I walk on bare-headed. As the path gets nearer down to the river there is more cultivation. A few Bread-fruits begin to appear and Bananas. Every now and then a Monkey's Ear-ring (*Pithe-*

*columbium filicifolium*) throws a deeper shade than usual over the path. They are in great beauty now, bearing masses of the curled red seed-pods which give the tree its name, and there are fresh pale shoots among the old growths of sombre green with about the same relation of colour as in Yew, though the foliage is much less dense.

At the tenth milestone from Kingston the river plunges into an inaccessible gorge. A cutting through the rock carries the path round the hill to meet another valley, and after a mile, which is comparatively level, it zig-zags steeply down to Gordon Town. This is one of the most charming pieces of the road. There are Cocoanuts and Star Apples (*Chrysophyllum*) which diffuse a wonderful light of old-gold from the lower side of their leaves.

At and near Gordon Town several streams meet, forming the Hope River. A driving road begins here, but the valley is still narrow and picturesque with steep cliffs, which just give foothold to an occasional Aloe. Three miles further down we reach the Liguanea Plain, which slopes gently down to Kingston and the sea. The walk of eleven miles is done, and I put on my jacket and get into the electric car, which will take me down the remaining six miles.

Everything is green. I think this is the first thing that would strike a stranger. With our hot sun one expects to see the place burnt up. It is so in spring and again in the late summer.

And now begins the glory of the Poincianas. There are not many, but each one tells from a long way off. One has eyes for them alone. What we observed at Mavis Bank is even more noticeable here. The Hibiscuses, which are plentiful, pale their ineffectual fires. They are swept out of sight as stars before the sun. It is wonderful and without seeing incredible. The only other things I look at to-day are the No. 11 Mangoes, hung with ripe and ripening fruit, in shape a Kidney Potato, in colour a Greengage Plum, and quite as good though in a different way. They are selling twelve for a quatty (1½d.), and each has as much upon it as a moderate-sized Apple.

The Poincianas and Mangoes are with us all the way to town, which is reached at 9.30. Two hours suffice for business and breakfast, and I turn homeward. People who live in Kingston complain of the heat. A visitor for the day does not feel it because the sea breeze is then blowing. The hottest I felt was between one and two o'clock in the gorge near Gordon Town, where the sun poured down and the breeze slackened. The pull up to Guava Ridge is severe on this side. Yet I have often been hotter over a piece of walking in Switzerland. I got back at five o'clock in time to water the garden.

W. J.

### SOCIETIES.

#### KIDDERMINSTER AND DISTRICT HORTICULTURAL SOCIETY.

##### OUTDOOR CHRYSANTHEMUMS.

MR. E. C. NEWMARCH, F.R.H.S., took the chair at the monthly meeting of this society, held on Wednesday, September 10, when Mr. D. B. Crane, of Highgate, delivered a most interesting and enjoyable lecture on "Outdoor Chrysanthemums." After giving a sketch of the history of the flower, the lecturer dealt in turn with the questions of propagation, cultivation, and other points in a most lucid manner. Mr. Crane's instructive paper was much appreciated, and he was accorded a hearty vote of thanks. Mr. William Sydenham, of Tamworth, was also warmly thanked for sending a beautiful collection of blooms to illustrate the lecture, such kinds as Horace Martin, Goacher's Crimson, Ralph Curtis, Irene Hunt, Norbet Purvieu, and Mons. Louis Lionnet being particularly admired. The next lecture will take place on October 8, when Mr. F. G. Treseder, of Cardiff, will lecture on Dahlias.

#### CHARLBURY AND DISTRICT HORTICULTURAL SOCIETY.

ALTHOUGH the exhibition held at Charlbury, Oxfordshire, on the 28th ult. was the second of its kind, there appears to be sufficient enthusiasm in this society to make the future ones a still greater success. Mr. H. W. G. Morris, the indefatigable secretary, is largely responsible for the success which has so far been achieved. Exhibits have greatly increased, two large tents failing to house all the produce entered for competition. The show was held in the picturesque grounds, Lee Place, through the kindness of Captain Waller,

and although the weather was threatening at times it kept fairly fine.

Fruit was very well shown, the three competitors in a class for six distinct kinds making an interesting display. First prize was won by Mr. Vernon Watney, Charlbury Park, Charlbury, with superb Nectarines, Apricots, Peaches, Grapes, Figs, and a splendid Melon; Viscount Dillon was second, his Melon being in the pink of condition, and his Apricots superb. For two bunches of Grapes, Mr. Cook, Ascott, staged two beautifully even bunches with large berries and remarkably handsome colour; second prize was won by Viscount Dillon. A handsome Melon secured first prize for Viscount Dillon, the second award falling to the lot of Mr. F. T. Maisey, Charlbury. Most of the dessert fruits were staged for flavour, those for culinary purposes being adjudicated upon by weight.

Vegetables were finely shown, and also completely filled one of the large tents. Separate classes respectively for Cucumbers, Celery, Carrots (both stump-rooted and intermediate), Onions, Potatoes, Tomatoes, Turnips, Scarlet Runners, and Peas were well contested. The chief prize winners were Viscount Dillon, Captain Waller, Messrs. F. T. Maisey, F. Arnold, F. Bowley, Cook and Edgington.

Plants were rather poorly represented. For a specimen flowering plant Mr. Vernon Watney was first with a trellis-trained Almond, and for a foliage plant Captain Waller secured premier honours with *Adiantum cuneatum*. A pretty class was that for two vases of Roses arranged for decorative effect. In this instance Messrs. Taylor and Sons, Kingham, were first with a beautiful pair, lovely blossoms in a pleasing variety of colour and form, tastefully set up, well meriting first prize; charming also were the two vases exhibited by Mrs. H. W. G. Morris, Charlbury.

The dinner table decorations were a centre of interest. A simple yet elegant arrangement of the Harebell and just a few plumes of some of the smaller grasses made a most dainty display. This was the winning set, and came from Messrs. Taylor and Sons; Mrs. Morris was placed second with an arrangement of Sweet Peas, the colours being pleasingly associated; third prize was awarded to another display of Harebells and grasses, in which the grasses were too freely used.

Twenty-four grand Cactus Dahlias secured leading honours for Messrs. Taylor and Son; Mr. Corbett, Taston, being placed second. Messrs. Taylor and Son were again to the fore with Pompon Dahlias, showing a pretty lot of blooms; second prize in this class was won by Mr. J. Simmonds, Charlbury. The Sweet Peas in the competition promoted by Mr. Robert Sydenham, of Birmingham, created a delightful picture so late in the season. The blooms were large, of good form and colour, and the positions were keenly contested. Mrs. Morris, however, was a good first, followed in order by Mr. F. Bowley and Mr. G. King. There were other Sweet Pea competitions of equal merit.

An amateur's section, and one also devoted to cottagers, embracing flowers, fruits, and vegetables, made the show a most comprehensive one. There were in all some 134 classes, and in most instances the competition was good. To accomplish so much speaks well for the enthusiasm and hard work of the secretary and executive, and there is no reason whatever why this society should not make its influence felt throughout the county.

#### DAHILIA EXHIBITION AT THE ALEXANDRA PALACE.

THE central hall of the Alexandra Palace presented a very pretty appearance on the occasion of the annual exhibition of the North Middlesex Dahlia and Horticultural Society. The show was a very good one, and reflected great credit on the society, which is only two years old.

Among the large trade exhibits, the finest was that of Messrs. J. Cheal and Sons, who obtained the gold medal. Silver-gilt medals went to Messrs. Cutbush and Son, and to Mr. J. T. West, who also sent collections of cut blooms. Mr. A. Such was given a silver medal for early-blooming Chrysanthemums.

A fine display of hardy flowering plants, such as Phlox and Sunflowers, furnished by Mr. A. Perry, Winchmore Hill, gained a silver medal. Two noteworthy contributions were by the Alexandra Palace trustees, one being a beautiful group of Palms, Ferns, and foliage plants, and the other a collection of flowers and vegetables grown in the Palace grounds.

#### THE CRYSTAL PALACE FRUIT SHOW.

No one expected as good an exhibition of fruit as usual, therefore no one was altogether disappointed by the display in the Crystal Palace on September 18, 19, and 20, when the Royal Horticultural Society held its annual show of British-grown fruit. Competition in many classes was not keen, and in some there were no exhibitors at all. The large displays of hardy fruit usually made by the leading fruit growers were missing, and this fact alone largely accounted for the dull and unattractive appearance of the show, another reason of this being the want of colour in the Apples and Pears. Considering the early date of this year's exhibition, soft fruits, such as Peaches, Nectarines, and Plums, were not so good as might have been expected. Grapes were the best feature of the show; in fact, Grapes at all the leading shows in various parts of the country have been exceptionally good this year, so apparently this generally unsatisfactory season has been suitable to their culture. The Rev. W. Wilks, Mr. Reader, Mr. S. T. Wright, Mr. Humphreys, and their assistants deserve the best thanks of both exhibitors and visitors for the excellent arrangements made for them.

#### DIVISION I.—FRUITS GROWN UNDER GLASS OR OTHERWISE. GARDENERS AND AMATEURS ONLY.

Collection of nine dishes of ripe dessert fruit: First, Mr. H. Goodacre, Elvaston Castle Gardens, Derby, with an exhibit of great excellence. The Muscat of Alexandria and Gros Maroc Grapes, Peaches Exquisite and Sea Eagle, Pear Marguerite Marrillat, Apple Washington, and Melon The

Countess were splendid; second, Mr. J. Lock, gardener to Sir C. Swinfin Eady, K.C., Oatlands Lodge, Weybridge. His Muscat of Alexandria Grapes were very good, and so were Dryden and Rivers' Orange Nectarines and Barrington Peaches; third, Mr. J. Barson, Hinchingbrooke Gardens, Huntingdon. Peaches Sea Eagle and Barrington were good, and a huge Melon named Countess, whose nomenclature we much doubt.

Collection of six dishes, ripe dessert fruit: First, Mr. W. Mitchell, Chilworth Manor Gardens, Romsey, Hants, with a very good exhibit. The Grapes were good, also Peach Princess of Wales and Nectarine Pitmaston Orange; second, Mr. W. Harrison, Hallingbury Place Gardens, Bishop's Stortford, with a fairly good display; third, Mr. W. Howe, Park Hill Gardens, Streatham Common.

Six bunches of Grapes, distinct: First, Mr. W. Shingler, Melton Constable, Norfolk, with splendid Alicante, Gros Colman, large Muscats fairly well finished, and the same may be said of the bunches of Mrs. Pince. Gros Maroc and Alwinck Seedling were the other varieties shown; second, Mr. J. H. Goodacre, with huge, well-coloured Barbarossa, good Gros Maroc, and Muscat Hamburgh. There was no competition for four varieties of Grapes.

Three bunches of Black Hamburgh: First, Mr. W. Mitchell, Chilworth Manor Gardens, Romsey, with splendidly finished bunches; second, Mr. J. H. Goodacre; third, Mr. G. Lane, Highfield Gardens, Englefield Green, Surrey.

Mrs. Pince, three bunches: First, Mr. W. Taylor, Tewkesbury Lodge Gardens, Forest Hill, with fair bunches. There were no more competitors.

Alicante, three bunches: First, Mr. H. H. Brown, Castle Hill Gardens, Englefield Green, with very good, well-finished examples; second, Mr. W. Shingler, with enormous bunches, carrying a better bloom than the former, but unshapely; third, Mr. W. Taylor, Tewkesbury Lodge Gardens.

Madrestield Court, three bunches: First, Mr. W. Mitchell, Chilworth Manor Gardens, with fairly good fruit; second, Mr. J. H. Goodacre; third, Mr. W. Taylor. None of the Grapes in this class were first-rate.

Any other black Grape: First, Mr. W. Shingler, with splendid Gros Colman; second, Mr. George Lane, with very good Apple Towers; third, Mr. W. Mitchell, who showed Gros Maroc.

Muscat of Alexandria, three bunches: First, Mr. W. Lane, gardener to Sir E. Durning Lawrence, Bart., King's Ride, Ascot, with beautiful bunches of perfect finish; second, Mr. J. Lock, Oatlands Lodge Gardens, Weybridge, with less shapely and not so well finished bunches; third, Mr. C. Sutton, Chevening Park Gardens, Sevenoaks, with good bunches, though somewhat green. There were eight more entries.

Any other white Grape, three bunches: First, Mr. George Lane, Englefield Green, with excellent Chasselas Napoleon; second, Mr. W. Taylor, Tewkesbury Lodge Gardens; third, Mr. Goodacre, both with the same variety.

Collection of hardy fruit, grown in the open, thirty dishes, distinct: First, Mr. W. Lewis, East Sutton Park, Maidstone, with fruits of good size, though they altogether lacked colour; Apple Peasgood's Nonsuch and Pear Clapp's Favourite were the best dishes; second, Mr. E. Coleman, North Frith Gardens, Tonbridge, with some good fruits, though none had any colour; third, Mr. Berryman, Knighton Grange Gardens, Chichester.

Collection of hardy fruit grown under glass, twelve dishes, distinct: First, Mr. Goodacre, Elvaston Gardens, with some handsome fruits. Pears Souvenir du Congrès and Marguerite Marrillat, Peaches Princess of Wales and Sea Eagle, and Apple Ribston Pippin were splendid. Mr. R. Edwards, Beechy Lees Gardens, Sevenoaks, was second with smaller fruits. There were no more entries.

#### DIVISION II.—NURSERYMEN.

Table of fruit grown entirely out of doors, 48 feet by 6 feet: First, Mr. H. Berwick, Sidmouth Nurseries, Devon. Mr. Berwick had a very good display of Apples and Pears. Some of the best dishes, although they were not really up to the usual standard, were Apples Lord Derby, Warner's King, Autumn Pearmain, New Haworthian, Gloria Mundi; Pears Souvenir du Congrès, Pitmaston Duchess, Beurre d'Amanlis, &c. Messrs. H. Cannell and Sons, Swanley, Kent, were second. Their exhibit was very well arranged, but the fruits lacked the size of those in the first prize exhibit. Some of the best dishes were Lord Derby, Bismarck, Warner's King, Lord Suffield, and Winter Hawthornden.

A similar exhibit to cover tabling 32 feet by 6 feet: First, Messrs. J. Cheal and Sons, Crawley, with a good display. Some of the Pears were very good, notably Pitmaston Duchess, Glou Morceau, Catillac, Beurre Nigan, Doyenné Boussoch, and others; Messrs. J. Peed and Son, West Norwood, were second. Some of the dishes were very good, and some again were very small.

Table of hardy fruit, 16 feet by 6 feet: First, Mr. G. Mount, Canterbury, with an exhibit that contained some good well coloured dishes; Apples Cox's Pomona, Peasgood's Nonsuch, Lord Suffield, Worcester Pearmain, Grenadier, and others were of the best; second, Messrs. S. Spooner and Sons, Hounslow, who also showed well, having good dishes of Apples particularly; Messrs. J. Laing and Sons, Forest Hill, were third.

#### DIVISION III.—MARKET GROWERS ONLY.

Cooking Apples, four varieties, about 42lb. in baskets or boxes: First, Mr. H. T. Mason, Rectory Farm, Hampton Hill, with splendid Lane's Prince Albert, The Queen, Lord Suffield, and Bismarck; second, Mr. W. Poupart, Marsh Farm, Twickenham, whose Peasgood's were excellent.

A similar exhibit of dessert Apples, about 20lb.: First, Mr. George Chambers, Mereworth, Maidstone; second, Mr. W. Poupart, Marsh Farm, Twickenham.

Dessert Apples, two varieties, in baskets or boxes: First, Mr. H. T. Mason, who had good fruits; second, Mr. A. Wyatt, Hatton, Middlesex. Similar exhibit of cooking Apples: First, Mr. G. Chambers, Mereworth.

Pears, two varieties, in two packages of about 20lb. each: First, Mr. A. Wyatt, who showed Souvenir du Congrès packed in shallow boxes; second, Mr. George Chambers.

Pears (dessert) suitably packed for market: First, Mr. W. Poupart, with good Pitmaston Duchess; second, Mr. A. Wyatt, with Souvenir du Congrès.

Collection of twelve varieties of Apples and six of Pears: First, Mr. W. Poupart, Twickenham, who had good fruits of Peasgood's Nonsuch, Warner's King, Lane's Prince Albert, and Lord Derby Apples; and Pitmaston Duchess and Marguerite Marrillat Pears; a good second, Messrs. W. J. Lobjoi and Son, Heston Farm, Hounslow.

Cooking Plums, in basket or box, about 25lb.: First, Mr. W. Poupart, with splendid Monarch; second, Messrs. W. J. Lobjoi and Son, with Monarch also.

Dessert Plums suitably packed for market: First, Messrs. W. J. Lobjoi and Son, Heston Farm, Hounslow, with Coe's Golden Drop.

Peaches, twenty-four fruits, packed for market: First, Mr. J. Gore, Albion Nursery, Polegate; second, Mrs. W. J. Nay, The Homestead, Breuton (gardener, Mr. Buckingham).

#### DIVISION IV.—FRUITS GROWN IN THE OPEN AIR.

##### GARDENERS AND AMATEURS ONLY.

Apples, twelve dishes, distinct: Equal firsts, Mr. W. Jones, Wallington Bridge Gardens, Carshalton, and Mr. William Lewis, East Sutton Park Gardens, Maidstone. Both these exhibits contained some very good fruits, fairly well coloured and of good size.

Cooking Apples, six dishes: First, Mr. A. Bassile, Woburn Park Gardens, Weybridge, with excellent Ecklinville, Warner's King, and others. There were no more exhibits in this class.

Dessert Pears, eighteen dishes: First, Mr. W. H. Bacou, Mote Park Gardens, Maidstone, who showed splendid Beurre Mortillet (one of the best dishes in the show), Director Hardy, Triomphe de Vienne, &c.

Dessert Pears, twelve dishes: First, Mr. A. Bassile, Woburn Park Gardens, with a good exhibit, Marguerite Marrillat, Doyenné du Comice, Pitmaston Duchess, and Beurre de Mortillet were the best.

Dessert Pears, nine dishes: First, Mr. William Jones, Wallington Bridge, Carshalton, with good Mn. Treyve, Pitmaston Duchess, Urbanière, &c.

Dessert Pears, six dishes: First, Mr. R. Edwards, Beechy Lees Gardens, Sevenoaks, with very good Louise Bonne, Triomphe de Vienne, and Beurre d'Amanlis; second, Mr. W. Mancey, Upper Gatton Park Gardens, Merstham, with some very good Pears also.

Peaches, grown entirely out of doors, three dishes: First, Mr. C. Earl, Somerhill Gardens, Tonbridge, with good Sea Eagle, Princess of Wales, and others; second, Mr. J. H. Goodacre, whose best dish was Sea Eagle.

Peaches, grown out of doors, three dishes, distinct: First, Mr. C. Page, Dropmore Gardens, with good well-coloured fruits; second, Mr. Joseph Sparks, Grove House Gardens, Roehampton Lane.

Peaches, grown out of doors, one dish: First, Mr. W. Humphries, Home Lacy Gardens, Hereford, with very good Barrington; equal second, Mr. W. Mitchell, Chilworth Manor Gardens, Romsey, and Mr. J. Lock, Oatlands Lodge Gardens, with Sea Eagle.

Nectarines, outdoor, three dishes, distinct: First, Mr. C. Earl, Somerhill Gardens, Tonbridge, with highly-coloured fruits; second, Mr. T. Turton, Sherborne Castle Gardens, Dorset.

Nectarines, outdoor, one dish: First, Mr. J. Lock, Oatlands Lodge Gardens, Weybridge, with very good Dryden; second, Mr. J. H. Goodacre, with Violette Hatte.

Plums, nine dishes, three dessert, six cooking: First, Mr. G. Grigg, Ashburnham Place Gardens, with some excellent dishes, notably of Jefferson, Rivers' Late Gage, Black Diamond, &c.; second, Mr. W. Pope, Highclere Castle Gardens, Newbury, with good fruits also.

Plums, six dishes, two dessert, four cooking: First, Mr. C. H. Colegate, Catsfield Place Gardens, Battle, with good dishes; a good second, Mr. T. Turton.

Plums, three dishes of Gages, distinct: Second, Mr. J. H. Goodacre.

Dessert Plums, one dish: First, Mr. T. Turton, Sherborne Castle Gardens, with excellent Jefferson; second, Mr. James Vert, gardener to Lord Braybrooke, Audley End.

Cooking Plums, one dish: First, Mr. Grigg, Ashburnham Place Gardens, with Magnum Bonum; second, Mr. T. Turton.

#### DIVISION V.—SPECIAL DISTRICT COUNTY PRIZES.

##### GARDENERS AND AMATEURS ONLY—OPEN TO KENT GROWERS.

Apples, six dishes, distinct: First, Mr. E. Coleman, North Frith Gardens, Tonbridge, with highly coloured Worcester Pearmain, good Warner's King, and Peasgood's Nonsuch; second, Mr. R. Edwards, Beechy Lees Gardens, Sevenoaks.

Dessert Pears, six dishes, distinct: First, Mr. E. Coleman, North Frith Gardens, who had good Duronéau, Pitmaston Duchess, and Beurre d'Amanlis; second, Mr. Richard Edwards, Beechy Lees; Triomphe de Vienne was his best dish.

OPEN TO SURREY, SUSSEX, HANTS, DORSET, SOMERSET, DEVON, AND CORNWALL.

Apples, six dishes, distinct: First, Mr. C. H. Colegate, Catsfield Place, Battle, with good Lady Sudeley and Warner's King; second, Mr. T. Turton.

Dessert Pears, six dishes, distinct: First, Mr. Turton, Beurre de Mortillet, Alexandre Lucas, and Triomphe de Vienne being the best of a good lot; a good second, Mr. C. H. Colegate.

OPEN TO WILTS, GLOUCESTER, OXFORD, BUCKS, BERKS, BEDS, HERTS, AND MIDDLESEX.

Apples, six dishes, distinct: First, Mr. W. Strugnell, Rood Ashton Gardens, Trowbridge, Dutch Codlin and Annie Elizabeth being the best; second, Mr. C. Page, Dropmore Gardens.

Dessert Pears, six dishes, distinct: First, Mr. W. H. Bannister, Cote House Gardens, Westbury-on-Trym, Bristol, Doyenné Boussoch, Beurre Hardy, and Pitmaston Duchess being very good; second, Mr. C. Page, Dropmore.

OPEN TO ESSEX, SUFFOLK, NORFOLK, CAMBRIDGE, HUNTS, AND RUTLAND.

Dessert Pears, six varieties: First, Mr. W. Harrison, Hallingbury Place Gardens, Bishop's Stortford, with very good fruits.

OPEN TO LINCOLN, NORTHAMPTON, WARWICK, LEICESTER, NOTTS, DERBY, STAFFS, SHROPSHIRE, AND CHESHIRE.

Apples, six dishes, distinct: First, Mr. W. H. Divers, Belvoir Castle Gardens, Grantham, with very good Lane's Prince Albert, Warner's King, The Queen, &c.; second, Mr. Henry Knott, Stamford.

Dessert Pears, six dishes, distinct: First, Mr. W. H. Divers, Beurre d'Amanlis and Beurre Superfin being the best dishes; second, Mr. Henry Knott, Stamford.

OPEN TO WORCESTER, HEREFORD, MONMOUTH, GLAMORGAN, CARMARTHEN, AND PEMBROKE.

Apples, six dishes, distinct: First, Mr. J. Rick, Morastow House Gardens, Ross, with very good fruits, Bramley's Seedling and Warner's King being of the best; second, Mr. J. E. Jones, Kynaston Gardens, Ross.

Dessert Pears, six dishes, distinct: First, Mr. J. Rick, who showed very good Durondeau, Doyenne Boussoch, Triomphe de Vienne, &c.; second, Mr. W. Humphreys (gardener to the Earl of Chesterfield), Home Lacy.

OPEN TO GROWERS IN THE OTHER COUNTIES OF WALES.

Apples, six dishes, distinct: First, Mr. H. Forder, Ruthin Castle Gardens, North Wales; second, Mr. Fox, Highmead Gardens, Llanbythor, South Wales.

Dessert Pears, six dishes, distinct: First, Mr. H. Forder; second, Mr. Fox.

OPEN TO THE SIX NORTHERN COUNTIES OF ENGLAND AND THE ISLE OF MAN.

Apples: First, Mr. George Picker, Hesslewood Gardens, Hull, with very good fruits; second, Mr. J. McIndoe, Hutton Hall Gardens, Guisborough.

Dessert Pears, six dishes, distinct: First, Mr. McIndoe, with good Beurre Benoist and Pitmaston Duchess; second, Mr. George Picker.

#### OPEN TO GROWERS IN SCOTLAND.

Apples, six dishes, distinct: First, Mr. James Day, Galloway House Gardens, Garliestou, N.B. Mr. Day was first for Pears.

#### OPEN TO GROWERS IN IRELAND.

Mr. J. G. Weston, Bessborough Gardens, Kiltown, Ireland, was first for six dishes of Apples in the class open to Irish growers only, with excellent fruits.

#### DIVISION VI.—SINGLE DISHES OF FRUIT GROWN IN THE OPEN AIR.

The chief prize winners in these classes for Dessert Apples were Messrs. John McKenzie, T. Turton, F. W. Thomas, W. Harrison, G. Craib, W. P. Bound, D. G. McIver, C. Earl, T. Clinch, T. W. Herbert, J. Lock, Alex. Smith, W. Mitchell, A. J. Carter, Charles Ross, E. Coleman, W. H. Bannister, and J. Rick.

##### COOKING APPLES.

The chief prize winners were Messrs. Alex. Smith, E. Coleman, W. Lewis, A. Bassile, J. E. Jones, J. McKenzie, T. W. Herbert, C. Earl, C. Sutton, F. W. Thomas, D. McAinch, T. Turton, D. G. McIver, Charles Ross, A. J. Carter, W. H. Divers, and W. P. Bound.

##### DESSERT PEARS.

The chief prize winners were Messrs. A. Bassile, A. J. Carter, E. Coleman, W. H. Bannister, J. Rick, T. Turton, W. Lintott, G. Grigg, T. W. Herbert, J. W. Banks, T. H. Slade, W. Howe, D. McAinch, F. W. Thomas, T. Horsey, Charles Ross, and C. Page.

#### DIVISION VII.—MISCELLANEOUS.

##### HOME-PRESERVED OR HOME-BOTTLED FRUITS.

The Horticultural College, Swanley, won the first prize in this class (wholesale firms excluded) with what appeared to be first-rate produce. Miss A. Bassett, Shirley, Croydon, won the second prize, the third prize going to the Lady Warwick Hostel, Reading.

##### HOME-PRESERVED OR HOME-BOTTLED BRITISH-GROWN FRUITS (OPEN).

First, Messrs. Austen and Co., St. James Works, Kingston-on-Thames, who showed a great variety of jams and bottled fruits; second, Britannic Fruit Preserving Co., Tiptree Heath, Kelvedon, Essex; third, the Horticultural College, Swanley.

Twelve bottles of bottled fruits: First, Allanson Bailey, Esq., Mount Pleasant, Farningham (gardener, Mr. W. Elliott); second, Mr. J. Bushnell, Sandling, Maidstone; third, Mrs. Banks, Hasland Hall, Chesterfield.

Mrs. W. H. Plowman, Beddington Corner, Mitcham, was given first prize in a miscellaneous class for fruits and jellies.

##### NON-COMPETITIVE EXHIBITS.

Mr. George Eunyard, Maidstone, had a splendid exhibit of orchard fruit and pot fruit trees. The latter, arranged at the back of the stand, comprised trees of Apples, Pears, Peaches, Figs, Cherries, and Grapes. The dishes of fruit arranged below contained amongst them some excellent fruits, notably of Apples Peasgood's, Duchess of Gloucester, Grenadier, Duchess of Oldenburg, Emperor Alexander, Lady Sudeley, and many more. Of Pears, Conseiller de la Cour, Uvedale St. Germain, Princess, Beurre Bâle Pére, Marguerite Marrillat, Parrot, and Pitmaston Duchess were splendid. Plums, Nectarines, Crabs, Prunes, including Burbank's Giant (new), Filberts, Peaches, &c., were also included in the exhibit, which was one of great excellence.

Messrs. James Veitch and Sons, Limited, Chelsea, exhibited a group of Pear trees in pots that were carrying good crops of fruit. Beurre Fouqueray, Priuecess, Beurre Superfin, and Emile d'Heyst were of the best.

Messrs. B. R. Davis and Sons, Yeovil, Somerset, displayed some grand blooms of tuberous Begonias in splendid sorts.

# THE GARDEN

No. 1611.—VOL. LXII.]

[OCTOBER 4, 1902.

## FASHIONS IN FLOWERS.

**E**VEN among those who truly love their gardens there are many people who are content just to follow the prevailing flower fashion of the day, and, without thinking for themselves, to accept what is perhaps only a fancy of the moment as a standard of excellence that they are bound to follow.

Just now there is a conspicuous example of this in the present fashion in the form of the Cactus Dahlias. In these capital flowers it appears that the only ones that are now in favour are those with the narrow half-tubular florets more or less twisted, forming a starry outline. One of the best growers assures us that nothing else in the way of garden Dahlias is now in demand, and that the older decorative sorts, with wide, flat petals are no longer asked for and cannot be sold.

This is extremely regrettable, as it is just these wide-petalled Dahlias that are of all their kind the ones most useful in good gardening for grand effects of colour in the late summer and autumn. It is not to be denied that the starry flowers have a prettiness and refinement of form that will befit them for the show table and for room decoration, but to let these be the only garden Dahlias that we may now have seems to us a sheer perversion of good taste and good sense. Beautiful though some of the most free blooming of them are, there is scarcely one among them that for honest and simple garden use can approach in value such of the older flatted-petalled kinds as, among the reds, King of the Cactus, Cochineal, Lady Ardilaun, and Fire King; among yellows, William Pearce, Lady Penzance, and Lady Primrose; or such fine things as Henry Patrick among whites. To let this grand type of a good flower fall into disuse is to neglect some of the very best flowers we can have in our gardens.

We cannot but think that this exclusive approval of the starry, twisted-petalled flowers among the garden Dahlias is but a passing fashion, and would earnestly counsel growers not to lose sight of the fine old kinds such as those just named. Some of the most thoughtful and practical amateurs would not on any account be without them, and, though admitting and admiring many of the starry kinds, would never allow these to claim precedence of their more useful brethren.

Probably the taste for the newer kinds is to a large extent an artificial one. It may be

that it is overfed by honours on the show table, and it would appear that it holds its present position more on account of the comparative novelty of form than as the result of a just appreciation of true beauty. The newer forms certainly cannot claim consideration for garden utility in comparison with the best of the older Dahlias.

Another class of this good flower that, according to the evidence of the nurseries and the shows, is falling into disuse is that of the large-flowered, low-growing kinds. A few years ago there were grand things among these, already excellent and showing infinite promise, and of distinct utility in garden decoration.

We ask ourselves what is the meaning of these freaks in Dahlia fancy. In the case of the old show flowers we know exactly where we are. They are for the competitions of the Dahlia societies and for the pleasure of those who honestly enjoy their rigid perfections. They have their place, though that place may not be in the most beautiful gardens. But why a grand development of a good flower should be thrust aside in favour of a form of lesser utility it is difficult to understand. Are there so few people who care about the truer aspects of garden beauty, or is it that growers are so anxious to raise prize-gaining varieties of the newer pattern that nothing else is put before the horticultural public at the shows?

We do not desire to decry the narrow-petalled Dahlias, but to remind amateurs of the extreme garden value of the good kinds that for a time at least are not receiving the consideration that is so justly their due.

## A HIGHLAND GARDEN.

SCOTLAND is famous for her hills and lochs, her grouse and purple moors, but none the less for her gardens and gardeners. There is nowhere throughout the Highlands a more charming old-world garden than this of which I write. Seen in midsummer it was a blaze of colour, fragrant with many scents, and bright with summer flowers, but now, in autumn, the garden has only added fresh beauties to its old delights. We complain sadly of the lateness of the season, but surely it is a matter of small complaint that we should still be in full possession of Raspberry and Currant bushes loaded with ripe red fruit. Wonderful to relate the Strawberries are only just over, a belated few still left among the leaves that have turned bright scarlet and brown. Roses seem to be the only flowers that August has taken away with her, though the Rose border is not quite bereft, and some still cling to the trellised doorway as though loth to leave us,

while the garden gateway is covered yet with masses of Crimson Rambler. One of the charms of these Scotch gardens is the custom of planting the fruits of the earth with the flowers and having no particular kitchen garden.

There are no ugly rows of the necessary Potatoes and Cabbages, unrelieved by anything more frivolous than a Lettuce bed. Tall Sweet Pea hedges and gorgeous Hollyhocks grow in friendly proximity to homely vegetables, and mingle their scent with Sage and Thyme from the herb border.

Carnations are only just out in this late season, and burst their tight green envelopes, glowing scarlet and pearly white. Carnations are trying flowers to gather, because of the forest of buds on every stalk; sometimes I am forced to leave a beautiful bloom on account of about seven baby flowers that grow on the short stalk. The borders in this garden seem an ever-changing band of colour. Tall Sweet Williams, dear old-fashioned flowers that they are, grow stiffly in large clumps, red and white, and Wallflowers, forgetful of the season, are actually coming into flower, seeming to bring a reminder of spring into my autumn garden. The borders are full to overflowing with blazing Calceolarias, modest Pansies (we call them kittens' faces), yellow Daisies, and a wilderness of Poppies. At one end of it I know where to find a York and Lancaster Rose bush, sacred to these old gardens, and in a secluded nook are clusters of Violet roots, a faint fragrance still seeming to cling round the leaves, a relic of departed spring. Near all the summer flowers blow quantities of autumn ones—Asters, many-coloured Stocks, and velvety-striped Marigolds. The gardener prides himself upon many new kinds of flowers, but we turn impatiently from the unfamiliar names to gather handfuls of sweet Mignonette, of which we never tire.

Under the sunny west wall stand a row of bee hives, whose crowds of busy workers pass in and out laden with honey from moor and garden. On the ground by the hives the massacred drones lie in heaps of slain, while in the security of the hive the queen lays her eggs. This Ross-shire garden in its exquisite trimness recalls Milton's remark: "Retired leisure, that in trim gardens takes his pleasure." The sunshine casts quaint shadows on the straight Box-edged paths, the gardener's pride, a soft wind rustles the Elms, while in the distance (seen through a tiny door in the wall) stretch a glorious range of blue hills standing clear against the sky. Perhaps the crowning glories of this Highland retreat are the tall hedge of clipped Holly, many years old, and the double avenue of ancient Cypresses, ending in a quaint semi-circle of Laurels. The picturesque stiffness of the grey-green Cypresses harmonises well with the atmosphere of bygone times in the rest of the garden, its broad Box hedges and bowing-green shut off by encircling copper Beeches and gigantic Planes.—D. H. D.

## KEW NOTES.

## INTERESTING PLANTS IN FLOWER OR FRUIT.

## Temperate House.

ACACIA LINEARIS, Berlandiera tomentosa, Crowea saligna, Grevillea alpina, and Musa Ensete.

## Water Lily House.

Gourds in fruit as follows: Benincasa cerifera, Lagenaria enormis, L. leucantha var. longis, L. vulgaris, Luffa acutangula, Momordica Charantia, M. cochinchinensis, and Trichosanthes Anguina.

## Orchid Houses.

Erides odoratum, Brassavola grandiflora, Cattleya bicolor, C. loddigesii var. Harrisonae, Cynorkis Lowii, C. purpurascens, Cyprypedium Charlesworthii, C. cossianum, C. Maynardii, C. spicerianum, C. tonsum, Dendrobium formosum var. giganteum, Epidendrum ciliare, E. raniferum, Lelia pumila var. praestans, Lelio-Cattleya callistoglossa, Liparis elata, Miltonia candida, M. Clowesii, M. Regnelli, M. spectabilis var. moreiana, Odontoglossum andersonianum, O. grande, O. madrense, Polystachya Buchananii, Rodriguezia fragrans, Saccolabium gemmatum, Selenipedium grande, Sobralia xantholeuca, Stanhopea oculata, and Strelitzia discolor.

## T Range.

Haemanthus coccineus, H. crassipes, H. Lindeni, H. tigrinus, Klingia notoniana, Mesembryanthemum tigrinum, Nerine curvifolia, N. sarniensis, Oxalis purpurea, Passiflora Galbana, Pavetta hispidula, Pitcairnia aphelandraeflora, P. maidifolia, Phyllanthes pulcher, and Tillandsia duvaliana.

## Succulent House.

Aloe latifolia, A. obscura, A. pachyphylla, Asparagus aethiopicus, Bomarea edulis, B. oligantha, Opuntia Dillenii, and Solandra grandiflora.

## Greenhouse.

Among other things the following are conspicuous: Angelonia salicariæfolia, Coxcombs, Erica caffra, Hibbertia dentata, Peristrophe speciosa, and Primula Forbesii.

## Herbaceous Plants.

Asters in variety, Bidens grandiflora, B. leucantha, Callistephus hortensis, Campanula portenschlagiana, Colchicum in variety, Crocus asturiæ, C. nudiflorus, C. pulchellus, C. speciosus, C. zonatus, Kniphofias, Lilies, Sunflowers, &c.

## Orchid House Wall and Border.

Abutilon megapotamicum, Amaryllis Belladonna, Capparis spinosa, Gerbera Jamesoni, Gladiolus purpureo-auratus, Raphiolepis indica, Schizostylis coccinea, and Watsonia marginata.

## Shrubs.

Aralia spinosa, Arbutus Unedo, Clematis (various), Fuchsia macrostemma and varieties, Hibiscus syriacus, Hydrangea paniculata, Hypericum (various), Ligustrum lucidum, L. Quihoui, Spiraea mongolica, and Ulex nanus.

## NOTES OF THE WEEK.

## FORTHCOMING EVENTS.

October 7.—Royal Horticultural Society, meeting of committees, Drill Hall, Westminster; National Chrysanthemum Society's Show, Royal Aquarium (three days); National Chrysanthemum Society, meeting of Floral Committee; meeting of Scottish Horticultural Association; National Dahlia Society, committee meeting, Horticultural Club, 3.

October 16.—Annual Dinner of the United Horticultural Benefit and Provident Society, Holborn Restaurant.

October 20.—Meetings of National Chrysanthemum Society's Floral and Executive Committees.

October 21.—Royal Horticultural Society, meeting of committees, Drill Hall, Westminster.

October 28.—Croydon Chrysanthemum Show (two days).

October 29.—Kent County Chrysanthemum Show at Lewisham (two days); Highgate Chrysanthemum Show (three days).

**Royal Horticultural Society.**—The next fruit and flower show of the above society will be held on Tuesday next in the Drill Hall, Buckingham Gate, Westminster, 1-5 p.m. A lecture on "Experiments with Chemical and other Manures" will be given by Mr. F. W. E. Shrivell at three o'clock. At a general meeting, held on Tuesday the 23rd ult., thirty-six new Fellows were elected, making a total of 934 elected since the beginning of the present year.

## Royal Horticultural Society's Examination in Horticulture, 1903.

The Royal Horticultural Society will hold its annual examination in the principles and practice of horticulture on Wednesday, April 22, 1903. The examination will be held simultaneously in as many different centres in Great Britain and Ireland as circumstances may demand. A centre can be established wherever a magistrate, clergyman, schoolmaster, or other responsible person accustomed to examinations will consent to act on the society's behalf in accordance with the rules laid down for its conduct. No limit as to age, position, or previous training of the candidates will be imposed. The new syllabus is now ready, and intending candidates should send a penny stamp for a copy of it. Copies of the examination questions set by the society's examiners in previous years, price 1s., complete, can also be obtained on application to the Secretary, Royal Horticultural Society, 117, Victoria Street, London, S.W.

## United Horticultural Benefit Society—annual dinner postponed.

The annual dinner of this society, announced to be held on Tuesday next, has been unavoidably postponed. It will now be held at the Holborn Restaurant (Throne Room), High Holborn, on Thursday, the 16th inst., at 6.30 p.m. Arthur W. Sutton, Esq., F.L.S., V.M.H., will preside.

**A Dahlia conference.**—Arrangements are being made for the holding of a conference, under the auspices of the Dahlia Society, on the judging of Cactus Dahlias in September, 1903, on the afternoon of the first day of the annual exhibition. The conference will be opened by a paper from Mr. C. G. Wyatt. The exhibition will be held at the Drill Hall, Buckingham Gate, the arrangements being similar to those for the exhibition held recently, and the conference will take the place of the fortnightly lecture of the Royal Horticultural Society. Several new decorative classes will be added to the schedule for next year.

**The proposed conference on Cactus Dahlias.**—In agreeing to hold its annual exhibition again next year at the James Street Drill Hall, the executive of the National Dahlia Society have also wisely resolved to hold in place of the usual lecture a conference on Dahlia judging, thus bringing the address and discussion into close harmony with the nature of the exhibition. That course will doubtless tend to attract to the show many who take more than a passing interest in the Dahlia. Should the council of the Royal Horticultural Society determine to hold a vegetable exhibition in the same place next year a very fitting subject for a lecture might be "The Proper Cooking of Vegetables." With respect to the Dahlia judging conference, which Mr. Wyatt, of Salisbry, has agreed to open on the lines of a paper read some time since before the Royal Horticultural Society in relation to points in judging Cactus Dahlias, very much interest should attach to it, for the obvious reason that with the exception of Mr. Wyatt no one seems to have attempted to lay down any principles on which such judging should be based. Really in Cactus Dahlias we have to deal with some of the most difficult of florists' flowers. Hardly any other kind or variety is there that does not lend itself to what are recognised as floral requirements, especially in relation to solidity, substance of petal, and outline. Cactus Dahlias differ greatly in form and size, and have petals of the most peculiar form, and also in build or substance. Colouring has little to do with point judging, as all good Cactus Dahlia flowers are beautiful. It is therefore no easy matter to lay down any clearly defined rules of judging in relation to these flowers. Then in the past they have been almost exclusively regarded from the

show standpoint—artificially supported and set up. That is a false or misleading aspect by which to judge of their merits. Of one variety that will make a good garden decorative plant, and that should be a primary rather than a third rate consideration, there are twenty that have no such fitness. It is now high time in relation to all certificated new ones that garden decorative fitness should be made a primary consideration. Kaisers keep on pouring in seedlings during the autumn, and far too many of these obtain certificates of merit that have only large show flowers on weak stems, but are worthless in the garden. The result is that buyers of these new ones when they grow them are greatly disappointed. It would be no exaggeration to say that one half of the certificated seedlings of any one year are barely ever seen again. It is for this reason in any conference on the point judging of Cactus Dahlias that at least one-third of the points awarded should be for garden fitness. Then the more refined and beautiful the flowers so much the better.—A. D.

## Agapanthus umbellatus in tubs.

I saw a few days since, standing on the grass fronting a villa residence at Teddington, four very fine blue Agapanthus in tubs and in splendid bloom. I have seen larger specimens, but none better than these. They were in tubs 20 inches over and about 15 inches deep. The leafage was about 3 feet in diameter, and as each plant seemed equally flowered I counted the stems on one and found sixteen, all carrying quite large heads of rich blue flowers. These were specimens that would have fitly adorned the grandest garden in the kingdom; yet how seldom are good ones seen.

Immediately adjoining, in a similar garden, were several other fine plants in 12-inch pots in good bloom, but with these exceptions I see none others in thousands of similar or more pretentious gardens. These plants are not difficult to grow, and are half-hardy. While so beautiful and easy of culture, how many things not half so good or so readily grown are preferred.—A. D.

**Bush tree Apples.**—The remarkably fine examples of Lord Suffield, Bismarck, The Queen, and Lane's Prince Albert cooking Apples, shown at the Crystal Palace in bushels by Mr. H. T. Mason, of Hampton Hill, Middlesex, were grown on quite small bush trees only two years planted, with the exception of the Prince Albert, which came from older bushes. I saw these bush trees a few days since. Many then, especially Cox's Orange, were carrying fine crops of beautiful fruits nearly close to the ground. All the trees are worked on the Paradise stock at home, and they thrive remarkably well on the comparatively stiff loam of the district. The planting is unusually close, 6 feet by 7 feet, although for a few years there is ample room between them for such surface crops as Strawberries. When they are some seven or eight years old they are very thick. It seems to be the rule to plant out a breadth of newly-worked bush trees every year, and none seem allowed to remain unduly long on the ground. Pears on the Quince stock thrive as well as Apples do. The samples mentioned were of the very finest at the recent fruit show.—A. D.

**Hibiscus rosa-sinensis.**—Despite the dull, damp summer we have experienced, some plants of this tropical or semi-tropical shrub have flowered well in Battersea Park in the open ground, and kept up a succession of bright-coloured flowers for a considerable period. This Hibiscus, which is a native of China and Japan, was introduced into this country in 1731, and either the typical kinds or some of its many varieties are often to be met with in gardens. Among the different forms both single and double flowers occur, while they also vary considerably in colour. In one variety (Cooperi) the leaves are marked irregularly with bright and dark olive green, creamy white, and crimson, while they have also a reddish border. In tropical countries Hibiscus rosa-sinensis is largely planted for ornament. As recently as page 223 it is referred to in notes from a Jamaica garden, while here, if kept under glass throughout the summer, it needs to be fairly exposed to sun and air, otherwise the flowers will be but few.—H. P.

**Rudbeckia Newmanni at Waterlow Park.**—Excellent use has been made of this coneflower at Waterlow Park, Highgate, N. Planted in bold masses in various positions and equally varied aspects, convincing proof is given here that the plant thrives well in suburban London. Plants in this quarter of the northern heights are exposed to London fogs for quite a long period, and to come through the ordeal and succeed so well says much for the splendid constitution this Rudbeckia possesses. Just now these large groups are making a most effective display. The rich orange-yellow flowers with velvety maroon centre cone are developed in dense masses from late summer until autumn is well advanced.—D. B. C.

**Chrysanthemum early-flowering Pompon Mme. Ed. Lefort.**—This is very distinct. From the earliest days of September the plants are indeed a picture, and prove most conclusively what an excellent subject the early-flowering Chrysanthemums are for the hardy flower garden in the early autumn months. Although the plants rarely exceed 2 feet in height, they are of free growth. At the time of writing the plants are in full blossom. The whole of the flowers stand out well and make a free display of beautiful Pompon flowers with fimbriated florets. Their value is enhanced because it is quite unnecessary to disbud the plants to obtain the display referred to. The majority of the flowers, too, open at about the same period, and, in consequence, the effect is very striking. The colour, as described by the catalogues, is old gold shaded with red, but it is not by any means dull, as this description might possibly lead one to suppose.—D. B. C.

**Pergola climbers.**—The large pergola at North Mymms Park is so well clothed with diverse climbers that a list of some of them, as I saw a few days since, may be interesting to many readers. Still, climbers which do well on pergolas will do well anywhere, provided soil and aspect be favourable. They are as follows: *Polygonum baldschuanicum*, very vigorous and effective; *Solanum crispum* and *S. jasminoides*, both very beautiful, but should have the stems protected in winter; *Clematis Flammula*, *paniculata*, *Viticella*, the yellow-flowered *graveolens*, *montana*, and *Nellie Moser* and *Marcel Moser*, both fine autumn bloomers, and very beautiful ones. Of Honey-suckles, *Lonicera halleiana* is very good, and seems to be always in bloom. The vines are excellent. The old white *Jasmine officinale* is always good, as also is the winter-blooming *J. nudiflorum* and *Eccremocarpus scaber*. If the roots be protected in winter it is a fine flowering climber, as also is *Cobaea scandens* if similarly treated. Of course *Wistaria sinensis* is included, as also is the old Tea plant *Lycium europaeum*, and the noble leaved Dutchman's pipe, *Aristolochia Siphon*. A good foliaged climber also is *Periploca graeca*. Of course numerous Roses are included, such as Crimson Rambler, Paul's Carmine Pillar, Alister Stella Gray, Bouquet d'Or, and others. Generally for pergolas the stronger-growing and harder climbers are the better, because they are needed to cover up so much that is in supports unsightly. Strong growers may be kept in check with the knife. Weak ones may do for panels, but hardly to clothe pillars. For panels, such a plant as *Ceanothus Indigo*, the most beautiful blue flowered of all, for a plant of which Mr. Fielder recently obtained a first-class certificate at the Drill Hall, do admirably.

—A. D.

**Lælio-Cattleya elegans var. Fritz Sander.**—To add to the bewildering number of forms of this splendid natural hybrid flowers have just been received from R. H. Measures, Esq., of Streatham, of a new and very distinct variety, named as above in compliment to one of the partners in the firm of Messrs. Sander and Sons, from whom the plant was originally acquired while still in the imported state. Some doubt may be entertained as to whether or not this is really an elegans. It is possibly a cross between the two natural hybrids *L.-C. elegans* and *L.-C. schilleriana*. Anyhow the question may be allowed to rest at present. It is so near to elegans that it

is better classed as a variety of that than add to an already burdened nomenclature, at any rate until actual experiment conclusively proves its correct parentage. Meanwhile it is well worthy of placing on record from its handsome and distinct characters. A two-flowered spike has been received, the individual blooms of which measure 6 inches across the petals, which, with the sepals, are of a deep shade of magenta-rose, the petals being much the broader of the two, strongly undulated, and covered with parallel and netted veins of magenta. Their substance reminds one of *Cattleya Leopoldii*, but there is no spotting. The lip exhibits a strong contrast of colour. The whole of the front lobe is of rich crimson, flushed with magenta-purple, almost violet in certain lights. This colour extends in a broad stripe to the foot of the column and also to the apices of the side lobes, but is darkest immediately beneath the anther cap. The sides of the tube are white, with, at the base of the lateral lobes, a suffusion of light yellow. Except the yellow the colours are the same on the exterior surface and occupy the same areas, but if anything they are of a lighter shade. Around the whole of the coloured portion of the lip, the margin of which is beautifully frilled, runs a very narrow white border. The lateral openings so conspicuous in most varieties of *L.-C. elegans* are quite rudimentary, the median and side lobes having a practically uninterrupted outline. The column is purple-crimson.—*ARGUTUS*.

**Manettia bicolor.**—Early in July I saw a fine plant of this tropical American twiner, mentioned by Mrs. Gwytherne-Williams in her note on "Tender Shrubs and Trees" (page 193) as succeeding in the open in the Isle of Wight, in full bloom in a garden in the neighbourhood of Penzance. The example was 6 feet by 6 feet, and was covered with its brilliant scarlet and yellow tubular flowers. *Asparagus Sprengeri*, also referred to by the same writer, does well in the open in southern Cornwall, but not being a flowering shrub or climber was naturally omitted from the list of those subjects.—S. W. F.

**Erythrina umbrosa.**—How is it that this tree of surpassing brilliancy, mentioned by Mr. A. Kingsmill in his charming "Impressions of a Cruise Amongst the West Indian Islands," is not alluded to in either Nicholson's or Johnson's horticultural dictionaries? Has it another specific synonym? It is, when in flower, as Mr. Kingsmill rightly says, a never-to-be-forgotten sight. After the lapse of twelve years the vivid impression still remains of a blossoming branch flung across a glade in the high woods of Trinidad, the glorious orange-scarlet flaming against the perfect blue of a West Indian sky.—S. W. FITZHERBERT.

**Senecio Galpini.**—One of the most interesting groups of flowering plants at the present time in the Cape house at Kew is composed of this rare South African composite. It was discovered in the Transvaal about eleven or twelve years ago, and seeds of it were sent to Kew by Mr. Galpin. Whether in or out of flower it is very ornamental, the leaves being handsome enough to warrant its culture for their sake alone. Before it arrives at the flowering stage it forms a dense rosette of fleshy and glaucous leaves 1 inch to 1½ inches wide and from 3 inches to 6 inches long. When strong enough a flower stem is pushed up from among the leaves to a height of from 9 inches to 15 inches, and on this heads of rich orange-coloured blossoms are borne, the heads often being from 1½ inches to 2 inches across. The plants at Kew are growing in pots, but it has also been tried with success planted out in the rock-work in the Mexican house. Outdoors a number of plants are to be seen in a bed in the herbaceous ground, but the unusually wet summer has not been very favourable for them. For planting out in a sunny position on a rock garden it would no doubt be an acquisition for the summer months, especially in those places where Mesembryanthemums thrive. *Kleinia Galpini* is another name under which this plant has been seen.—W. D.

**Gerbera Jamesoni.**—In a warm, sunny border at the foot of the Orchid house wall at Kew this Gerbera has been flowering freely for several weeks past and has still a number of flower

buds to open. Although it has not been cultivated in European gardens for many years it has attained a fair amount of notoriety on account of its brilliant coloured flowers. It is recorded in the *Botanical Magazine* as having been first discovered by the collector Rehman about 1878, and afterwards by Mr. Jameson in the goldfield district of Barberton, and by Mr. Wood of Durban Botanical Garden, and by Mr. W. Nelson on the Latrobe River. It is figured in the *Botanical Magazine*, t. 7087, and in THE GARDEN for October 12, 1889, the figures having been prepared from a specimen grown and flowered at Kew, which had sent by Mr. Wood from Natal the year previously. In the description accompanying the coloured plate in THE GARDEN it is stated that Mr. Tillet of Norwich first introduced and flowered the plant in 1887. It forms a large mass of leaves arranged in a rosette-like manner on a thick root-stock. The blades are 10 inches or more long, the petiole being 6 inches or 7 inches long. In shape the leaves resemble to a certain extent those of the Dandelion, but are deeply lobed and heavy. The flower-heads are 3 inches to 4 inches across, on long, upright, slender stalks 12 inches to 15 inches high, and the ray florets, which are flame-coloured, are the chief attraction. In general appearance the flower-heads are very like those of *Mutisia decurrens*. For a warm border where there is plenty of sun this plant is an excellent subject, while for a sunny, airy greenhouse it is a fine plant for pots.—W. DALLMORE.

## NOTES ON HARDY PLANTS

### HEUCHERA.

**O**N page 194 of THE GARDEN mention is made of a hybrid Heuchera which I am said to have raised. However, like many other good hybrids have done, owing to my practice of allowing strange spontaneous seedlings to mature, it raised itself, having come casually and uninvited in a border.

Twenty years ago I recollect not more than three or four species of Heuchera in my garden; the best was *H. micrantha*, with large plumes of small white flowers showing red in bud, that colour being sometimes so pronounced as to have given rise to a synonym *erubescens*. Then there was *H. hispida*, syn. *H. Richardsoni*, a vigorous plant with tall panicles of colourless flowers and ornamental foliage marked with bronze. A third species was *H. cylindrica*, with larger green flowers growing more compactly and nearer the form of a spike. I think I also grew *H. americana*, which seems to have gone, being of little merit. The introduction of *H. sanguinea* from North Mexico about twenty years ago made quite a new era in the cultivation of the genus. I think Messrs. Ware had the credit of first offering it, and its pure soft red flowers and neat habit at once commended it to growers of hardy flowers, but it soon showed a serious failing, as in the northern counties of England, including Cheshire, it could scarcely be called hardy. It was much crippled and disfigured by a hard winter, especially if the winter extended into spring, and though it might survive the flowering which is due in May was much damaged if not destroyed.

*H. sanguinea* has become the parent of a very varied race of hybrids, all of them hardier than itself, and many well worth cultivating, but requiring selection. I got *H. sanguinea* as soon as it was in the market, and not more than three or four years afterwards I noticed a seedling coming up in a bed in which no Heuchera had been grown, so I presume the seed passed through the rubbish heap and was

introduced in a surface dressing of soil. When it flowered I had no difficulty in determining its parentage to be *H. sanguinea* × *H. cylindrica*, as its characters were distinctly intermediate: the flowers are large and pink, not without a suspicion of green, and the habit robust and very hardy. The flowering, which is abundant, begins in May and lasts to the end of August, when a large second crop appears and is generally destroyed by frost before the end of October when in its prime. It took some years to persuade visitors to my garden that this hybrid was of any merit; they preferred the colour of *H. sanguinea*, which they said was spoilt in the hybrid, and this is partly true; but its good qualities have been recognised by several of the leading herbaceous amateurs, and I cannot supply cuttings fast enough for the demand which has sprung up. If asked for a name I should propose to follow the good example of Professor Sir Michael Foster, and mark the parentage as he has done in several hybrid Irises, so the name, instead of Edge hybrid, under which I have hitherto distributed it, will be Sancy. I should add that this hybrid is fertile, and that I have raised two or three crops of seedlings from it. Some of these are of the deep scarlet of the best forms of *H. sanguinea*, others are dull white, but none are as robust or free-flowering as their hybrid parent. I have given away many of these promiscuously. The only form I thought worth notice was one with scarlet flowers as bright as the best form of the type, and rather larger, but I am not sure that I have kept it distinct.

Another hybrid which came in two or three parts of my garden soon after the first is *H. sanguinea* × *H. hispida*. It seems to have come also about the same time in other gardens, as it soon appeared in catalogues under the general name of *H. brizoides* or *brizeformis*. Some of these have the bronzed leaves of *H. hispida*; all are very robust in habit, being almost too leafy, and have many large and tall panicles of red-pink flowers, which last a long time, but are not produced in succession. This also is sparingly fertile, but does not seem to produce anything noteworthy. A third form of hybrid which seems more variable than the other two is *H. sanguinea* × *H. micrantha*. In this the flowers vary in size between those of the two parents, and are of different shades of red. Two or three years ago I saw in Essex a large bed of this hybrid in which there were hardly two plants with flowers alike. The forms seem to pass into *H. brizoides*, and as all these hybrids appear to be more or less fertile it is likely that the hybrids may have crossed. It need hardly be said that careful selection should be made before perpetuating any of the forms, which may very easily be done by cuttings. All the kinds are better for frequent renewals from cuttings, but the cultivation of the type in its best forms should have special attention. It is worth while to give it the warmest and most sheltered situations to save it from injury by frosts, as the embryo buds are easily destroyed in winter in the open border, hence we hear frequent complaints that the species flowers very sparingly. In cold gardens it is worth while to give the plants the treatment common with Tom Thumb scarlet Geraniums, taking cuttings early in summer, growing them in a frame through winter in single pots, and planting them out in April. If planted out from the store pots the check will interfere with their flowering.

Patient selection and artificial crossing would probably produce a strain as hardy as *H. hispida* with the bright vermilion flowers of the im-

proved type of the species. Neither the hybrid I have called Sancy nor any of the brizoid forms show any tenderness by exposure to winter or spring frosts.

*Edge Hall, Malpas.* C. WOLLEY-DOD.

### VERONICA LONGIFOLIA SUB-SESSILIS.

I was surprised to read in Mr. Wolley-Dod's note about this handsome plant that it appeared to him "absolutely barren both in seed-bearing and in pollen." Ever since the plant was sent out, and, indeed, before, for I was in a way concerned with the original example at the Pine Apple Nursery, the mealy, almost biscuit-toned, pollen was quite conspicuous to the naked eye, and against the richness of the blue flowers was remarkably so. I am sending you a small scrap of bloom, such as I now have, to show that there is pollen in abundance, and in consequence my former remarks as to imparting some of its fine colour to the more weedy members of the race were amply justified. Moreover, if you closely examine the lowest portion of the inflorescence sent you will observe evidences of a swelling ovary—though doubtless infertile, for I have never gathered a seed that I remember—in every instance. This at least would indicate that careful fertilisation should bring the desired result. At the same time, it is curious that the plants at Edge are all barren, and have always been so. If, however, the barrenness is fully established it would be interesting to know the experience of others in more northern districts. So far as I am aware there is but one stock of this plant in circulation, unless the second introduction by Mr. Ware, as mentioned by Mr. Wolley-Dod be such, and this a barren stock. In the scrap sent the anthers are the same colour as the blossoms until the pollen cases burst and reveal the delicately toned pollen already described. In a few hours the pollen is quite ripe for use.

*Hampton Hill.* E. JENKINS.

### THE NIGHT-SCENTED STOCK.

Two plants apparently can lay claim to this title, namely, the annual *Hesperis tristis* and the perennial *Matthiola bicornis*. I noticed that Mr. Pettigrew, writing in the spring on "Fragrant Flowers," mentioned *Matthiola bicornis* as an annual. The plant that I have under this name is certainly not an annual, but is of dwarf, woody, shrub-like growth. I obtained it this spring from a friend, in whose garden it had been growing for three years. It has been flowering continuously ever since the beginning of June, and now holds a dozen or more flower-spikes. Its small blossoms, of a dingy purplish red tint, are certainly not attractive to the eye; indeed, they are so inconspicuous that nine out of ten persons would probably pass the plant by without noticing that it was in bloom, but in the evening the scent that they emit is delicious and is rivalled by few flowers. A native of Greece, it is of doubtful hardiness, but in the southern counties usually comes through the winter unharmed. All who love fragrant flowers and live in the warmer portions of these islands should grow *Matthiola bicornis*.

S. W. FITZHERBERT.

## THE FLOWER GARDEN.

### SOWING GRASS SEEDS ON LAWNS.

**W**ITHIN reach of most of our large towns the difficulty of securing good turf at a reasonable price has led to a larger use of seeds for lawn making, and if good seeds are sown thickly enough

and the seed bed properly prepared a good lawn can be obtained in a comparatively short time. The best season to sow is in September, as early in the month as possible. When the seeds are

sown in September there is usually moisture enough to secure germination, and the sower would, after the ground was prepared, wait till rain was expected, but I prefer sowing on a fairly dry surface, so that the roller can be used. It is important for the ground to be thoroughly cleared of the roots of perennial weeds, and all stones raked off, and made perfectly level and firm by rolling. If necessary the ground should be manured before being dug over and levelled, but it is so easy to manure grass land with either phosphates or nitrates in a concentrated form that the question of manuring can be settled after the grass seeds are sown, but the ground must be perfectly level and perfectly fine to prevent a settlement afterwards. The seeds should be obtained from a good source, and sown quite thickly; in point of fact it is next to impossible to sow the seeds too thickly to secure a good lawn in a short time. Supposing the seeds are sown in September, and the roller is used occasionally, then a lawn will be fit to play upon by the following June, if not earlier. As soon as the seeds are sown rake them in and roll down firm again. It will be an advantage if a top-dressing of rich compost can be given which has been passed through a half-inch screen, though I have seen good lawns made without any top-dressing, especially in the case of small lawns near the house. Basic slag, 5lb. to the square rod, applied in autumn or early winter, and 3lb. to 4lb. per rod of nitrate of soda in spring, will soon alter the character of any lawn which is weak and worn and requires help. If the seeds cannot be sown in September, the sowing must be deferred till March or April, the ground cleaned and prepared during the winter, and if the work is well done in March the lawn will be ready for use in June, but firmness and smoothness are essential; on a firm surface the turf soon gets thick and the grass fine.

E. HOPDAY.

### GOOD GARDEN TULIPS (SPECIES).

It is a good sign of an awakened interest in the Tulip when we see such firms as Messrs. Barr and Sons, Messrs. Hogg and Robertson, and Mr. W. B. Hartland, the latter both of Ireland, all paying marked attention to the flower. At the present time it is well to direct attention to some of the lesser known species of distinct beauty. Generally speaking, it may be said that few bulbous plants under cultivation improve so much as the species of Tulip, particularly when grown and kept under observation for several years in succession. Indeed, taking the comparatively small bulb as collected—frequently incapable of flowering the first year—and carefully noting both its weight as well as its dimensions, the grower will view with satisfaction at least the notable increase in these respects after only a moderately generous season or two of cultivation in good loam. Very naturally, too, what is so marked in these ways is equally so in vigour of leafage and its flowering. This is not merely satisfactory from the general standpoint, it is more, because it so unmistakably demonstrates how well adapted is Britain and British cultivation to the special needs of these beautiful spring flowers. The following can be recommended:

*T. Batalinii*.—Not a large Tulip, but dainty, about 6 inches high as a rule, and with pleasing flowers of a soft delicate primrose tone, with a deeper shade in the centre. For its size it is quite free flowering.

*T. biflora*.—The typical species is not, perhaps, of much note, but the variety known as "major," with its clusters of yellow flowers, often early in March, is welcome. Frequently the clusters of flowers are as many as four on a stem, in which particular it differs from any other known species of Tulip.

*T. clusiana*, the Lady Tulip, has the outer segments of a cherry red tone, and the inner ones white, with violet centre. It is a pretty Tulip, rarely exceeding 9 inches or 10 inches high. An old inhabitant of our gardens and a native of the Mediterranean region. It is quite hardy, however, and should be planted 5 inches deep.

*T. Didieri*.—A handsome May-flowering Tulip, with large crimson-red flowers blotched with a darker colour at the base. This is a native of the Alps, and attains 15 inches high. There are other forms of this. *Alba*, white, and delicately scented; *lutescens*, pale yellow, sometimes freckled with red, a handsome flower; and *aximensis*, dark red, margined yellow. All are worthy of culture.

*T. Eichleri*.—Flowers brilliant scarlet and very handsome flower stems rather less than 1 foot high. Early April.

*T. Greigi*.—This has handsome spotted foliage and huge brilliant blossoms that when fully expanded are of great size, displaying the distinct blotch at the base. It is best in warm, sandy soils. Native of Turkestan. There is a golden form of this, lightly freckled with red.

*T. elegans*.—An April-flowering Tulip, graceful, pleasing, and brightly coloured. The former character is imparted to it by the pointed, slightly recurving petals. The form of this known as *Lutea*, which grows 18 inches high, is perhaps the finest deep yellow Tulip grown, producing its giant cups of pointed sweetly-scented flowers. There is a white form edged with carmine.

*T. flava*.—Creamy yellow, sturdy and vigorous, 20 inches high, valuable as a late flowering sort.

*T. gesneriana*.—There is hardly any need to refer to this kind of Tulip, which, as the first parent, so to speak, of a great race, is made much of in every garden in the land. Bold, brilliant, and noble, no Tulip is showier. There are many beautiful varieties.

*T. kaufmanniana*.—A rare species from Turkestan, and certainly one of the most handsome. The flowers are of large size, creamy white, with a few streaks of red on the outside, and a big blotch of yellow inside. A very hardy Tulip, and improves greatly with judicious culture in sweet loam and sand. Flowers early in April. Height, 10 inches.

*T. Lownei*.—A rare and pretty species, 4 inches to 6 inches high. Flowers, soft rose-pink with yellow centre, the outer petals greenish.

*T. Leichtlini*.—A very pretty species, particularly in the stage just before expansion. In this stage the three outer segments are of bright carmine-red, revealing a broad white margin, as the flower expands. The inner petals are white and somewhat rounded. Native of Cashmere.

*T. saxatilis*.—A rather pretty Tulip of a delicate rose tint, with bright yellow centre. Height, under 1 foot. Native of Crete.

*T. pulchella*.—A charming species from the Alpine region of the Tauras Mountains. Flowers glowing crimson-carmine with yellow markings.

*T. suaveolens*.—Large brilliant scarlet and yellow flowers. A dwarf Tulip, flowering in April. A gem for cutting.

*T. sylvestris*.—A well-known native, 16 inches or 18 inches high. Flowers of a pleasing yellow shade and sweet-scented. Fine for naturalising.

*T. violacea*.—Rosy carmine, shaded violet, perhaps the earliest of all species. Warm spot in the rock garden is best for this kind. Under 6 inches high.

*T. vittellina*.—A fragrant Tulip of much merit, the finely-shaped flowers pale yellow, shading to a creamy tone. Height about 16 inches to 20 inches.

To these others may be added of much merit. At the same time, those named form quite a representative list.

E. J.

direct attention to them at the season of planting. Never before has such a gorgeous picture of colour been seen at a London show as that in the Drill Hall in the early spring months. Not only for colour but also for size and fulness did these handsome flowers appeal to all who saw them. Any amateur can grow the Anemones just as well with a little care and some generous treatment of the soil.

Perhaps the best soil is the lighter loam, that known as sandy loam, and this of good depth. Equally good is any soil rich in vegetable matter, and particularly the darker soils that retain some moisture at a short distance from the surface. The soils that do not, as a rule, agree with these plants are heavy and retentive, such as close clays.

But the amateur may now make his preparations for planting, firstly, by digging as deeply as the conditions permit; and, secondly, by the addition of plenty of decayed manure and leaf-soil. When planting the tubers should not be buried more than 4 inches deep, and may be surrounded by sand or not, according to the class of soil being dealt with. In the lightest of soils this will not be required, while in those of a more heavy and loamy nature sharp sand is always helpful.

Generally speaking, October and November are considered good for the planting of all this tribe, and in those gardens where it is known that winter frosts do no harm to the young leafage no time could be better. In those low lying localities where the leafage suffers in severe weather the latter part of November will be early enough for the planting of the first batch. From this time successive batches of the tubers or roots may be planted until March and even later. Though in these late plantings it may be seen that the tubers are of reduced size, they not only quickly plump up when planted and in contact with the soil, but yield a welcome late display. Naturally the finest flowers are the result of planting good tubers at the most seasonable time. Never plant the tubers too thickly. For those of medium size, a minimum distance of 6 inches and for the largest size roots 9 inches apart each way will not be too much for full development. Happily for those who make a feature of massed beds in early spring these showy flowers are among the cheap and good things of to-day. Indeed, the strain is of the

highest excellence throughout, the colours of exceptional brilliancy, and the flowers of a size and fulness we had not seen hitherto. These flowers when seen at the Royal Horticultural Society's meeting were admired by all.

### THE BEST MICHAELMAS DAISIES.

Few flowers have been so improved during the past thirty years as the Michaelmas Daisy. It was then a commonplace flower, planted in some out of the way corner or among shrubs and left to take care of itself; but grown in a border by itself there is no hardy flower that can in any way compare with it during the last fortnight in September and through October.

There are many varieties, many synonymous or almost so, so that great care is necessary in making a selection, which should be done and the various heights noted while they are in flower. The trial which is being made at Chiswick this season should prove of great assistance to all lovers of this charming plant, as a very large collection is being grown; hence one good reason why the Royal Horticultural Society should possess a good trial garden.

Fortunately the perennial Aster are not at all fastidious as to the nature of the soil, thriving in almost any kind, in any position, and no reasonable amount of frost or wet will injure them. Support against rough winds is, however, absolutely necessary. Especially must this precaution be taken when they are planted in exposed positions. Merely bunching up the growths to one stake is ugly and slovenly, as the beauty of many varieties is in their growth.

I have for many years made a special study of Michaelmas Daisies, and nothing has given me greater pleasure, as my labours have been much appreciated by my employers and the numerous visitors which annually come to see them when in flower. By careful hybridisation we have been fortunate in raising and bringing before the public many improved forms, habit of growth and free blooming having been my object. I have flowered many thousands of seedlings, which of necessity must be the case to obtain really distinct novelties.

PART OF THE ASTER (MICHAELMAS DAISY) BORDER IN THE GARDENS OF ALDENHAM HOUSE, ELSTREE, HERTS (THE RESIDENCE OF LORD ALDENHAM).

### THE "ALDERBOROUGH" ANEMONES.

THIS is the name given by the Messrs. Reamsbottom and Co., Ireland, to their beautiful strain of Anemones. These have been so frequently seen during the early part of the present year and so unanimously praised that a brief notice at the present moment will suffice to again

Like many other things the more common varieties produce seed more freely than the better forms. For the benefit of those who contemplate forming a collection I will as briefly as possible relate our mode of treatment. We devote a long border facing east to the Asters. It is of good width and backed by shrubs, the soil was in the first instance thoroughly manured and trenched during autumn and left rough till the spring, then forked over and levelled. Having made a careful note of what I considered the best kinds in the autumn, these were procured and planted at a distance of 3 feet all ways, carefully arranging the heights. Cinder ashes were placed round each plant to prevent slugs eating them, and the surface well mulched with half-decayed manure.

Except watering in dry weather and giving frequent hoeings little other attention was needed till July, when the plants were staked. Several stakes are used to each clump, and the growths neatly looped up as required. We replant, trench, and manure the border every two years, dividing the clumps into small pieces, and each season additions as to varieties are made, the less effective kinds having to give place to better ones.

After flowering the old growths are left till spring, as these are by no means uninteresting. The seed of the better kinds should be gathered immediately it is ripe, and sown either in autumn or early spring, pricked out into boxes when ready, and planted in the open in April in a sunny position, when they will flower the same season. I append a list of varieties, all of which are of great merit, and should be included in all collections.

*Novi Belgii* section.—Bacchus, candida, densus, Ella, E. G. Lowe, F. W. Burbidge, Harpur Crewe, Maia, Margaret, Purity, Robert Parker, St. Brigid, Theodore, and Top Sawyer.

*Nove Angliae* section.—Mrs. J. F. Raynor, praecox, rosea, rubra, and William Bowman.

*Amellus* section.—Onward, Distinction, Framfieldii, amelloides, bessarabicus, and Stella.

*Cordifolius* section.—Elegans, Diana, albulus, major, and magnificus.

*Other varieties*.—Hon. Edith Gibbs, Hon. Vicary Gibbs, Freedom, Delight, Arcturus, Aceris, Autumn Glory, Annie, Brightness, Coombefishacre, Triumph, Councillor W. Waters, Captivation, Charming, diffusus horizontalis, ericoides, grandis, Grace Darling, Chapmannii, levigatus, Madonna, Minnie, Nancy, puniceus pulcherimus, Pleiad, Ptarmicoides, Shortii, Tradescantii, Turbinellus, umbellatus, and vimineus perfectus.

EDWIN BECKETT.

*Aldenham House Gardens, Elstree, Herts.*

AMID his multitudinous duties in this charming garden, Mr. Beckett has found time to raise and grow to perfection several batches of improved forms of Michaelmas Daisies. In no private garden can such a collection of varieties and well-grown masses of these favourite autumn-flowering perennials be found. For years it has been my pleasure to pay an annual visit to these gardens at a time when the Asters are coming into flower. With such a collection Mr. Beckett has the material for extensive cross-fertilisation, and not only has he paid attention to colour, but has striven to improve individual growth and freedom of flowering. Having selected the best varieties to operate upon, excellent results have been achieved, and before long the public will no doubt have an opportunity to share in the benefit of Mr. Beckett's labour.

With a view to obtain compact, dwarf, and yet graceful growth and a maximum of freedom in flowering, such varieties as Pleiad, the Hon. Edith Gibbs, Cordifolius, and Coombefishacre were chosen as seed-bearers. The former is well known as quite the best of very dwarf-growing varieties, reaching little more than 1 foot in height and bearing a profusion of lilac-blue flowers. The second-named is itself a seedling from the well-known and popular ericoides.

Last year twenty-four varieties were tested and given names. Of these no less than six owe their parentage to Pleiad, of which the following is a brief description:—

Esther is exceptionally free-flowering, growing into a compact, round bush 3 feet high. The blossoms are a pleasing lilac tint of colour.

Fascination does not grow more than 2 feet to 3 feet high, compact in habit, with quite small leaves. The florets of the cup-shaped blooms are widely set apart, the colour lilac-blue.

Captivation flowers freely, the colour warm lilac-blue. It is quite pleasing; 3 feet.

Anne grows but 2 feet high, and forms a dense round head, freely covered with its lilac-blue shaded blossoms.

The Hon. Vicary Gibbs is of upright growth, 3 feet high, and has quite small leaves. The cup-shaped blossoms are from half an inch to three-quarters of an inch in diameter. The colour—bright lilac-pink—is pleasing.

Minnie is one of the most charming varieties yet raised, growing from 2 feet to 3 feet high, and most profuse in flowering. The colour is lilac, changing with age to a deep rosy shade of the same tint.

From ericoides several charming varieties have been raised, notably, the Hon. Edith Gibbs. Single stems grow 5 feet in height, and as much as 3 feet in diameter at the base. The horizontally-produced side growths are semi-drooping at the point, forming an elegant bush. The blooms are three-quarters of an inch in diameter, and, like its parent, is most profuse in flowering. The colour is of the palest mane.

From the Hon. E. Gibbs seven attractive varieties have been raised. Enchantress is quite an acquisition. The colour is lighter than its parent, while it retains other characteristics, such as habit, growth, and freedom in flowering.

Ideal and Osprey are also seedlings from the same source. The former is pale blue, while the latter is a warm lilac. Both are free and good.

From the Hon. V. Gibbs, itself a seedling from Pleiad, The Pearl and Gloriosa were obtained. Both much resemble Pleiad in colour. The growth is erect, the blooms small, but half an inch in diameter.

Gloriosa is quite an acquisition to any section, the colour is so striking. When unfolding it is white, changing to lilac, and then to deep purple with age. The growth is erect and its flowers are freely produced.

From Cordifolius, C. magnificus was obtained, and, like its parent, is quite profuse in flowering. The colour is bright blue; 4 feet.

From Cordifolius Diana, Profusus was obtained, and, as its name implies, it is exceptionally free in flowering; in growth it is stronger. The colour—pale blue—is pleasing.

That sterling variety, Coombefishacre, has been largely used as a seed-bearer, and, as might be expected, with good results.

Triumph is perhaps the best of the batch, growing from 4 feet to 5 feet high, single stems growing so vigorously as to measure as much as 4 feet in diameter. The blooms are large, pale lilac in the centre, deepening to rose at the edge. It is an exceptionally striking variety and especially free.

Grace Darling and Brightness are both from the same source, and acquisitions too. The former grows 3 feet high, forming a close, round head, thickly covered with blossom. The latter is fully  $\frac{1}{2}$  feet taller than its parent. The blossoms are identical in form and size, but the colour is bright pink. Delight only requires to be seen to be admired.

E. MOLYNEUX.

#### THE RETURN TO THE GARDEN.

If we were in the Palace of Truth and compelled to speak exactly as we think, most of us, I fancy, would have to confess that the coming back to our gardens after anything like a growing time of absence is never an unmixed joy. Much more often are we conscious of a feeling of dismay—and why? What can it be that makes everything appear to have gone wrong? Why does the Fern bank look so rusty and the rockery so overgrown? Why have the best-loved plantlets hidden themselves away and the naughty ones become too pushful? Why, in spite of weeding and

gardeners and caretakers and waterers, are all the corners we like to see quite moist, as dry as bones, and those we would fain keep high and dry grown dank as ditch water? Why have the climbers that had started on their course so nicely gone off upon a wrong tack exactly in the direction we had not designed for them, and why did those glorious Gladioli or autumn Crocuses or Roses or whatever it happens to be that we particularly wished to see in bloom—almost timing the home-coming with that idea—take the opportunity of flowering just when we could not watch them, and now are showing us nothing but withered pods or reddening berries?

It is not the gardener's fault, poor man! He has been doing his best, and the garden looks all right to him; he has mown the lawns and swept them, and weeded the paths and tidied up the beds. What has gone amiss is this—*his* mind has been going into the garden, not ours, and we feel the difference. It is one of the curious things about gardens that, like dogs, they only belong and respond to one person in a family. Other members may be called into consultation, may advise, and may enjoy, but the garden—if it really is a garden—belongs but to one. The eye of that one absent and the face of everything is changed.

When one comes to consider the matter one finds there are many reasons to account for the disappointment that is felt upon returning to our gardens. In the first place, there is the inevitable march of the season and the short-lived character of many flowers; there is the well-known waywardness of plants, and there is, too, the alteration in the focus of our own pair of eyes. Whatever we are accustomed to appears by force of habit to be right—to seem right even if it should be wrong. Custom even beautifies the ugly. Old ugly furniture, old ugly clothes, old ugly pets, how blind we grow to their defects! Then comes some period of weaning, and we suddenly see them in the abstract. In a way, this is good for us, and very enlightening.

With regard to gardens it is always the people who care most for them, and especially the sensitive and imaginative who suffer most. Those who tend and watch things growing do not merely see them as they are, but also as they are going to be. Imagination leaps into to-morrow and all the other to-morrows, and to a great extent we can by daily, hourly fashioning and moulding control the future of our flowers so that they grow up as we would have them. "True love in every form, even towards animals and plants, is watchful and ever-seeing, never missing for a moment what is for their good." So wrote a flower-loving lady, who elsewhere confesses to her own not infrequent feelings of, shall we call it disappointment, for want of a better word?—it is a sort of shock—at the first sight of her own home garden after absence from it. Has it grown smaller, darker? What is wrong? Instead of puzzling over these questions, and above all, instead of grumbling, the wise among us will speedily set to work to re-establish the lost *rapport*. As soon as the gardeners are not looking—we do not wish to hurt anybody's feelings—the stems that have been tied too stiffly are unbound and shaken into freedom, the creeper that had wound itself about the flower bush is untwined and twisted in the way that it should go. A touch here, a bending there, a weed to pull up, a gentle changing. At first the garden scholars will be wayward. Like children after too long holidays they are out of hand. Leaves will sulk when turned and show their backs unbeautifully, but only for a time—a very

little time. A gleam of sunshine and a freshening shower will right them, and only smiling faces will greet the master's eye.

There is a pleasant fiction in some families—I could almost believe in it myself—that plants thrive through being looked at almost as much as through being looked after. Of course this is only another way of saying that the master's eye is ever the quickest and most watchful, anticipating needs and righting wrongs unconsciously.

One more factor that makes up for the vague feeling of disappointment we sometimes feel on returning to our gardens is the way we have of over-idealising them in absence. Over-fond and too-imaginative people are apt to suffer pangs even in the joy of meeting their dearest ones again after a period of separation. It is a mistake to put the absent upon pedestals. With friends, and lovers, and husbands and wives, and children, and flowers and gardens, the same idea holds good; we must not remember any of them better than they are.

Enough about disappointment. The return to our gardens is often also the occasion of the pleasant surprise. Some wayward wildling we have coaxed in vain for long we find with joy has established itself at last. Finally, in its own way, it is flourishing. And what a lovely border is here of Heliotrope! It was nothing when we left it; now, what a mass of bloom and fragrance, and how pretty the bronze-brown Clover, with the golden flowerets, that has leapt across the pathway to form a background. How the pink-dyed Gloire de Dijons cluster among the purple blooms of the Clematis, and how the crimson Phlox flowers are burning as if lighted from within; or if it is a month later in the year how the gaily-coloured Chrysanthemums are heartening up the borders where still the Dahlias toss their dainty heads, the monthly Roses are turning a paler pink, and the Mignonette is just a little off—but, ah, how sweet! How much there is to see and do!

Household matters may be calling us, accounts that have to be made up, and sums that have to be put down, but it is next door to impossible to turn aside and leave the garden we are so glad to see again and within whose boundaries we fain would linger. Already the shyness is rubbed off that had come between us and the garden folk. Now we shall work together, again; sympathy is re-established. Well is it with the garden world that once more feels itself beloved, bewatched, betended, safely living and growing under the care of those who understand and love it best.

F. A. B.

## THE ROCK GARDEN.

### THE ROCK GARDEN IN SEPTEMBER.

**C**OLD winds and heavy rains are already making their presence felt, and remind us that the summer is practically a thing of the past. Nevertheless gardens, and especially rock gardens, judiciously arranged with a view to successive and continuous effect, are still bright in spite of the inclement weather. Many plants mentioned in my notes for August are still in bloom at the time of writing (middle of September), and of these I may mention the very interesting *Enothera rosea*, *Prunella grandiflora* and its white variety, *Polygonum vaccinifolium*, *Androsace lanuginosa*, and *Senecio Grayi*. I will now mention plants which have since come into bloom and are still flowering, some of them for the second time.

#### CLIMBERS NOW IN BLOOM.

A glorious climbing plant is now blooming out of doors in West Cornwall, namely, *Solanum Wendlandi*. It is almost too robust in its growth to be mentioned as a plant for the rock garden, but there is no reason why it should not be used for covering a cliff or wall of either natural or artificial rock if the rocks are on a scale bold enough to accommodate so strong a grower. I was much struck with its appearance last week in a garden near Truro. The leaves are leathery, varying from 3 inches to 6 inches in length, and from 2 inches to 4 inches in width; it bears enormous clusters of blue flowers with a suspicion of mauve at the base, and each individual flower measures 2 inches to  $2\frac{1}{2}$  inches across. In Messrs. Veitch's nurseries at Exeter there are several fine plants in bloom, but there the plants were in pots and not out of doors. The plant is a native of Costa Rica, and therefore tender, but it is hardy in warm and sheltered places in the south-west. Other climbers now in bloom—which, of course, would be suitable only for very large rocks—are the various Clematises of both the *C. Jackmani* and the *C. coccinea* type. The somewhat new hybrids, Countess of Onslow, Duchess of Albany, and Princess Beatrice, are also now in bloom.

#### DWARF ROCK PLANTS NOW IN FLOWER.

*Campanula Hendersoni* has opened its fine blossoms during the last week or so: the deep blue flowers are  $1\frac{1}{2}$  inches to 2 inches across, and very attractive. The plant is only about 6 inches or 9 inches high. Of other Campanulas now blooming I may mention the pale blue *C. hirsuta* and the little gem *C. Erinus*. The latter has deeply-toothed leaves and deep blue flowers. Most Sedums have passed out of bloom. The yellow *Sedum middendorfianum* flowered till the first week in September, and its leaves, now a deep red, are ornamental still. *Sedum sibiricum* with its deep crimson flowers is still exceptionally bright, and equally attractive is *Sedum Ewersii turkestanicum*, both on account of its glaucous foliage and its pretty heads of pink flowers which are just opening. Of Thymes I have only noticed *Thymus carnosus* as being now in bloom. It is larger in all its parts than most of the genus, and its prostrate stems covered with spikes of fine pink flowers are very pretty. The same might be said of *Helianthemum lunulatum* with its compact growth of grey leaves, now studded with yellow blossoms, and of the orange *Erigeron aurantiacum*, which is just blooming for a second time. *Hieracium rubrum*, which is in full bloom, is certainly a shade deeper than its orange companion, but it is not red in spite of the name, and as it has

the rambling habit of the ordinary Hawkweed it should be used with care. Very pretty still is *Dianthus versicolor* with its crimson blossoms, and *Chrysogonium virginianum*, which for a second time this year is unfolding its deep yellow flowers close to the ground. *Asteriscus maritimus* is also an exquisite plant for the rock garden, but it is hardy only in very sheltered places near the sea. The purple *Verbena venosa*, though not hardy in the North, is perfectly hardy here, and is now at its best. A very choice and rare rock plant now blooming is *Senecio leucophyllus*, growing only a few inches in height, which has silvery leaves and deep yellow flowers. Last, but not least, among dwarf plants in bloom I may mention *Cyclamen*

A SEEDLING ASTER, EDITH GIBBS, RAISED BY MR. BECKETT IN THE GARDENS OF ALDENHAM HOUSE.

*hederifolium* and other autumn-flowering kinds, which prefer a partly shaded position to one in the full sun.

#### MEDIUM-SIZED PLANTS NOW BLOOMING.

The following plants can of course not be associated with the smallest alpines, but might adorn the bolder rocks. In a moist and half-shady place the blue and the white forms of *Gentiana asclepiadea* are just now very attractive, as are also the following fine forms of *Chelone*, viz., *C. Lyoni* and *C. obliqua* with purple flowers, *C. barbata* with scarlet flowers, and *C. glabra alba* with white flowers. More sunny positions are required by the scarlet *Zauschneria californica*,

the blue *Plumbago Larpentæ*, and the pink *Sedum spectabile*. A very bright yellow flower with grey tomentose foliage is the American *Chrysopsis villosa* Rutteri. Of a deeper yellow is *Buphtalmum salicifolium*, which has deep green narrow leaves. *Coreopsis rosea* is not so large as the better-known *Coreopsis lanceolata*, but its flowers, which are just appearing, are of a pale rose colour, and its foliage is very ornamental. Of purple flowers the most conspicuous just now are *Linaria purpurea* and the glorious Tyerman's Groundsel (*Senecio pulcher*). Asters, too, are unfolding their blossoms. Among the prettiest, and, for the rock garden, most suitable kinds, I will only mention *Aster dumosus*, *Aster acris*, and *Aster Amellus bessarabicus*.

#### TALL PERENNIALS FOR THE BACK OF A ROCK GARDEN.

Of tall herbaceous plants now blooming there is still quite a large number, but chiefly such as are more suitable for the border or margin of the shrubbery than for the rock garden. Especially might this be said of the numerous Sunflowers, Rudbeckias, Solidagos (Golden Rod), *Helenium striatum*, *Tritomas*, &c. All these can only be used in the rock garden when they form the background and when a barrier of some kind is interposed between them and the dwarf rock plants. Most effective tall plants and well suited for bold rocks are *Desmodium japonicum* and *Desmodium penduliflorum* (syn. *Lespedeza bicolor*), the former with pink and the latter with purple flowers. Their arching shoots, covered with flowers at this time of the year and gracefully projecting beyond some prominence, give a natural and pleasing effect. Much stiffer and more sturdy is the scarlet *Lychinis chalcedonica* or the purple Rudbeckias *R. purpurea* and *angustifolia*. Particularly elegant is the tall yellow Rudbeckia Golden Glow, but it requires plenty of room.

#### WORK IN THE ROCK GARDEN.

Work is plentiful enough, for now is an excellent time for rearranging plants or for making additions to old or constructing new rock work. As, however, these operations will be exhaustively dealt with in another series of essays on the subject of "Rock Garden Making" I need not go into details here. As the wet weather seems likely to continue, drainage in the rock garden should now

be attended to, especially for plants which love a comparatively dry position, such as *Opuntias*, *Androsaces*, &c. With regard to such Androsaces, as have their leaves in large rosettes, care should be taken that these rosettes of leaves rest on stones and not on soil, where they would probably rot off during a wet season.

*Elmside, Exeter.*

F. W. MEYER.

## THE ROSE GARDEN.

### HYBRID TEA ROSE MME. JULES GROLEZ.

**S**EVERAL notes have appeared in THE GARDEN about this excellent Rose, and, having grown a number of plants of it, I can thoroughly endorse all that has been written about its good qualities. Introduced by M. Guillot as long ago as 1897, it seems to have been missed by many of those who grow Roses solely for beautifying their gardens and not for exhibition. In a season like that of the past summer it is a great deal to be able to say that no other Hybrid Tea has endured the inclement weather so well as this variety, and if I were asked to name the twelve best Hybrid Teas it would most certainly be included amongst them. Though not by any means a strong grower it is a robust and sturdy one, and holds its blooms erect on very stiff stalks, and never requires disbudding. At the time of writing (September 16) mildew is rampant, owing to a great extent to the very low temperatures which we have been registering. I notice, however, that the Hybrid Teas with stiff shiny foliage are not much troubled by this scourge, and in this category I would place the variety under notice, M. Bunnel, *Souvenir de Mme. E. Cauvin*, and *Violoniste Lévéque*. Nothing is more pleasing to the eye than the young foliage of most of the Hybrid Teas, and the beauty of Mme. Jules Grolez in this respect is very marked,

being further enhanced by its thorns, which are a bright red. Although Mrs. W. J. Grant is perhaps more brilliant in summer, when autumn comes I far prefer Mme. Jules Grolez. Its beautiful silvery pink blossoms reflex in a most charming manner, as will be seen in the illustration, while its firm petals seem to resist rain and damp infinitely better than Mrs. Grant. But whatever the season may be, Mme. Jules Grolez is an abiding acquisition. It has, alas! a fault—it is scentless.

*Worcestershire.* —ARTHUR R. GOODWIN.

### BEST ROSES OF THE SEASON.

#### BEST TWENTY-FOUR OF ALL CLASSES.

A NOTE from a London suburban gardener may be of some service, although not necessarily so to your original correspondent. All the Roses mentioned can be thoroughly relied on if attention is given to initial preparation of the ground.

#### TWELVE STANDARD ROSES FOR THE GARDEN.

The chief points taken into consideration in forming this list are: (1) strong growth, (2) freedom of flowering during summer and autumn, (3) hardiness, (4) variety of colour.

*Caroline Testout.*—Well known; at time of writing (September) two standards in my garden carry forty-nine flowers in all stages of development; one of the best of its colour; pink.

*La France.*—Silvery pink; too well known to need description; must have a cool root-run.

*Ulrich Brunner.*—Cherry red; makes a fine standard.

*Prince Camille de Rohan.*—The best dark red Rose for the garden; none of the dark red Roses are very good in the autumn, but this one is the freest.

*Marquise Litta.*—Carmine; an excellent flower; good shape; if treated well can be relied on.

*Captain Hayward.*—The best crimson; very free, and always opens well.

*General Jacqueminot.*—Another sweet-scented old Rose that should be grown; bright crimson.

*Mme. Hoste.*—Pale lemon; the hardest of the yellow Teas; very free-flowering.

*W. A. Richardson.*—Makes a fine standard; all shades of yellow; never without a bloom with me from June to November.

*Viscountess Folkestone.*—Flesh white large flowers, and very free; one of the best.

*White Maman Cochet.*—A Tea, but quite hardy with me; good grower, and magnificent flowers.

*Antoine Rivoire.*—A Hybrid Tea; creamy white, deeper in centre; free-flowering, and a good grower; flower opens flat, but fine shape otherwise.

All these recommended for standards can be equally well grown as dwarfs, with the possible exception of White Maman Cochet, which is at its best as a standard. I would, however, add the following

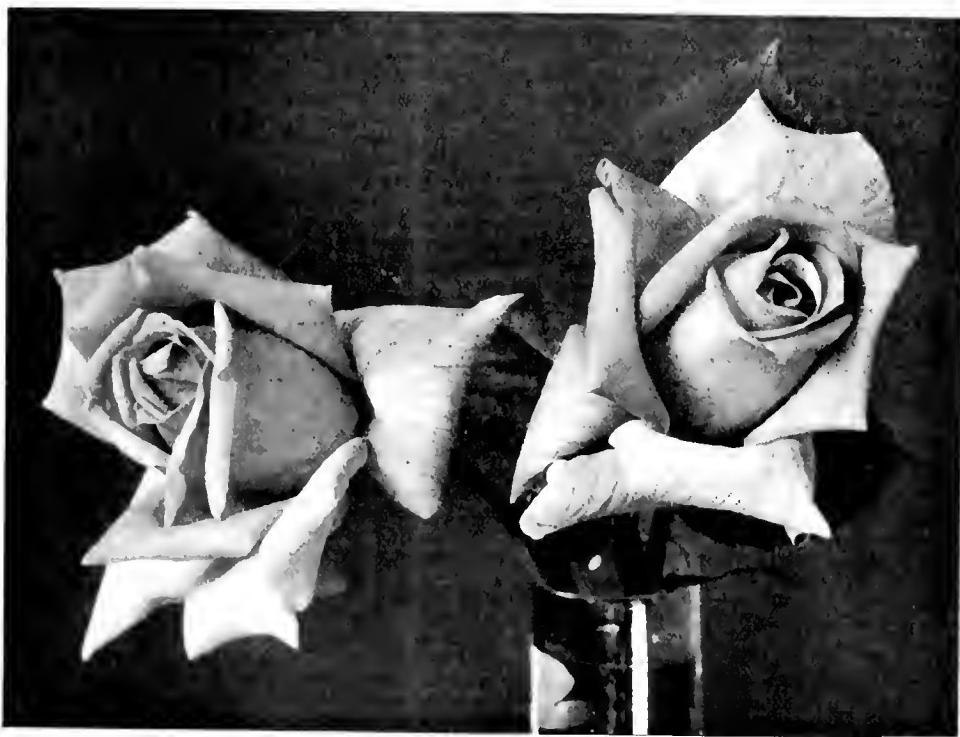

#### BUSH ROSES.

*Killarney.*—Blush pink; a Rose that does very well with me on a clay subsoil; its flowers are very beautiful.

*Mme. Abel Chatenay.*—A beautiful Rose, unique in its colouring and curious habit of twisting its petals like a Cactus Dahlia; a deep La France outer petal, deepening to salmon in centre.

*Mrs. John Laing.*—A well-known flower; good in every respect.

*Mme. Cadeau Ramey.*—A Hybrid Tea; very free-flowering; flesh tint, deepening to yellow.

HYBRID TEA ROSE MME. JULES GROLEZ (SLIGHTLY REDUCED).

at the base; has been very fine with me this year.

*Mme. Jules Grolez*.—A beautiful, though not large Rose; deep shade, clear pink.

*Grüss an Teplitz*.—A beautiful Rose; wonderful colour; very free-flowering; semi-climber.

*Maman Cochet*.—A fine Rose that has not been at its best this autumn, owing to the heavy rains, but it should be grown; for a Tea it likes rich, heavy soil. No garden should be without some of the

*China Teas*, such as *Mme. Eugene Resal* and *Laurette Messimy*, both excellent if one's choice is limited, and to finish my list of two dozen I will add

### THREE CLIMBERS,

and, still keeping in mind the original idea of autumn-flowering, *Mme. Alfred Carrière* is the best white; *Longworth Rambler*, bright pinkish crimson; and, as *Grüss an Teplitz* and *William Allen Richardson* have been already mentioned, I think I will add *Gloire de Dijon* to conclude my list.

I think your correspondent C. W. Crosby has rather misunderstood the original enquiry, or he would not have recommended such Roses as *Marchioness of Londonderry*, *Ulster*, *Bessie Brown*, *C. Gillemot*, *Helen Cambier*, *Kaisserin Augusta Victoria*, *White Lady*, &c.; they are not decorative garden Roses. If one has the space, the proper way to grow Roses for the decoration of the garden is to keep each sort distinct by planting it in a group or bed by itself. Treated in this way, all the following can be recommended: *La France*, *Caroline Testout*, *Viscountess Folkestone*, *Mme. Eugene Resal* (this is particularly good), and *Grüss an Teplitz* for dark red. All these Roses are fine bedders, and with the exception of the latter, which is rather taller in its growth, are of similar habit.

HERBERT E. MOLYNEUX.

*Brantwood, Bulham, S.W.*

### ROSES AT ROTHESAY.

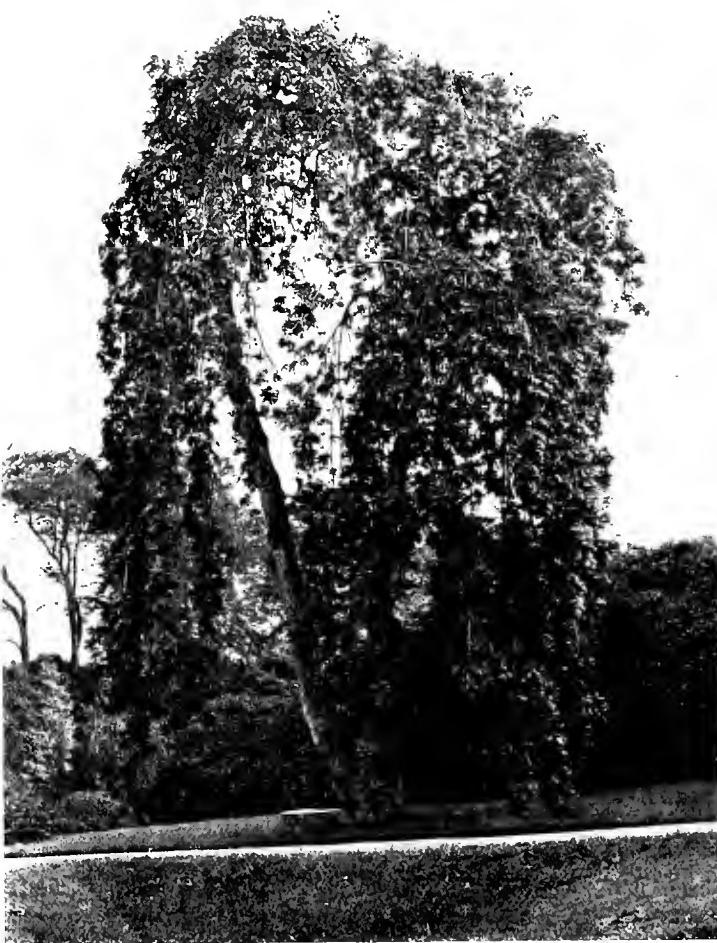

In a few weeks time many people will be preparing to plant a few Roses, and if they do not wish to be disappointed in their selection they will soon be placing their orders with their nurserymen. It is so difficult to select a few good varieties from the number which most firms catalogue that a few notes on one or two Hybrid Teas may not be out of place. This is not an ideal Rose growing district, being subject to late frosts and with a very large rainfall. A few varieties do very well, and some even better than I have seen them elsewhere. The following is a short description of a few:—

*Augustine Hamont*.—This is one of the newer Roses; the colour is of a deep rosy carmine on the outside of the petals, the inside of a silvery pink with a yellow base. The form is good, having a good depth of petal, the growth vigorous. This should be included in all collections where Roses are grown for cutting and decoration.

*Antoine Rivoire*.—The colour is a rosy flesh on a yellow ground, shaded with a border of crimson. It is a first-class garden Rose, the form good and the plant vigorous.

*Clara Watson*.—This is a first-class Rose for this

WEEPING ASH IN THE PALACE GARDENS, DALKEITH.

district, doing far better than I have seen it elsewhere; it is without doubt the best for this part of the country. It is a very pleasing colour, being of a pale salmon, tinted pink.

*Caroline Testout*.—The colour is a satiny rose, with a brighter centre, a fine large exhibition flower, but also a free bloomer. The plant is vigorous, and the flower of good form and very sweet scented.

*Grüss an Teplitz*.—This is a first-class autumn-flowering garden Rose, being very free flowering and of a semi-climbing habit. The flowers are in clusters, the colour being of a bright scarlet. The foliage itself is handsome—a bronzy green.

*Gustave Regis*.—This is a really charming Rose, exquisite in bud, which is long and pointed, the colour a deep canary yellow with orange centre, and a streak of crimson down the back of the petals; a beautiful buttonhole Rose.

*Liberty*.—A charming Rose, of a brilliant velvety crimson of an even shade throughout. The petals are well reflexed. It is a charming Rose in the bud, very free and vigorous, and beautiful for the garden or for decoration. It is spoilt for the exhibition table by being undersized.

*Mme. Abel Chatenay*.—This is just now (September) a charming picture, flowering here most profusely. It is of a carmine-rose colour, shaded salmon, the reflexed portion of petal being of a silvery pink. It is very sweet scented, and is one of the best Hybrid Teas for garden decoration, and should be found in all collections.

The above is not, of course, a complete list of the best Roses, but just a few that were noticed doing particularly well.

*Rothesay.*

G. M.

**LADY THORNYCROFT**, Steyne, Benbridge, near Ryde, Isle of Wight, writes:—The best autumn-flowering Roses in our garden here this autumn are *G. Nabonnand*, *General Shablikene*, *Marie van Houtte*, *Anna Olivier*, *Princess de Sagan*, *Mme. Alfred Carrière*, *Mr. Sharman Crawford*, and *Kaisserin Augusta Victoria*. All of these are full of blooms and buds, and are in the best of foliage.

*Princess de Sagan* is our only dark red Rose which looks in full health. It is altogether a most desirable Rose, each bloom remaining bright red until the petals fall.

*Mme. Alfred Carrière* is covered with blooms, and goes on flowering until well in November, and is a very charming Rose with delicious scent.

*Grüss an Teplitz* this year is not as good a colour as last year and has lost a great many of its leaves.

*Ulrich Brunner* looks very healthy and has some good blooms, but it is not a Rose I like at all.

*Mme. Cadeau Ramey* and *Mme. Abel Chatenay* are both lovely and have a few charming blooms.

*Sultan of Zanzibar*, *Fisher Holmes*, and *Prince Camille de Rohan* all look very ill indeed, but they were only put in last November, and have had a trying summer.

Of the *China Roses* *Laurette Messimy* and *Cramoisie Supérieure* are the best, each having a number of blooms.

*Alister Stella Gray* also is still in bloom, and *Wichuriana* is covered with buds and blooms.

*Gloire de Dijon* has not done well, but *William Allen Richardson* and *Rêve d'Or* are very good indeed.

**CAROLINE TESTOUT** has been, and still is, magnificent; *Viscountess Folkestone* the same; *Docteur Grill* is lovely now, as it has been all the

year. *Maman Cochet* and its white variety beautiful as usual. In the early part of the season *Margaret Dickson*, *Gloire Lyonnaise*, *Ulrich Brunner*, and *François Michelon* were finer than I ever saw them before. *Marie van Houtte*, *Augustine Guinoisseau*, *Mme. Ravary*, *Billiard et Barré*, *Francisca Kruger*, *Bridesmaid*, *Edith Gifford*, *Mrs. Cocker*, *Duke of Edinburgh*, *Duke of Wellington*, *A. K. Williams*, and *L'Ideal* have all done particularly well this year, and *George Nabonnand* is now splendid. It is the best of autumnales, but no use in the summer. *La France* and *Mrs. John Laing*, usually splendid in this garden, have done very poorly this year.

F. G. COLERIDGE.

*The Hermitage, Twyford, Berks.*

## TREES AND SHRUBS FOR ENGLISH GARDENS.

### WEEPING TREES.

**P**LANTING these with a niggardly hand is, after all, not what is wanted, that is, if we are to derive pleasure from their presence in combination with the general run of our park and woodland trees. Single specimens dotted about here and there, and planted ever so wisely, are by no means to be compared with those clumped or massed in threes or fives, and at irregular distances apart, a fact the truth of which dawned forcibly upon me when visiting a well-managed

and well-planted estate in the south of England. Generally, as seen, weeping trees like those of upright habit are planted singly, perhaps in appropriate enough situations, but in such a way as to give one the idea that the planter had this rigidly before him, that such a class of trees spoils the landscape, and requires to be very carefully dealt with and in unusually small numbers. Such ideas may have done well enough for the old school of planters, but nowadays hard and fast lines are not tolerated, and the departures from the strict routine of century-old ideas are nowhere more prevalent than in matters connected with trees and shrubs, their planting and after management.

A group of the Weeping Willow, some eight or nine in number, planted in no cramped or confined spaces, by the side of a fair sized lake, has a most pleasing and effective appearance, but they are planted far from any other trees and shrubs, and on the gently sloping, grassy bank, thus, I fancy, adding much to their charm and beauty. No single specimen of the same tree could have produced such an effect as this clump, which covered nearly a quarter of an acre, but yet did not look out of place, the size and outline of the grounds being boldly laid out and quite in keeping with the broad sheet of water. Within sight of these, but several hundred yards away, a mass of the red-stemmed Dogwood quite enlivened the end of the lake; while in a recess, where the margin of a plantation came nearly down to the water-side, were three fine old trees of the Hemlock Spruce, or rather what to me appeared to be a weeping form of this Canadian Conifer. These with their rich background of Scotch Firs had a truly imposing appearance, the long, cord-like twigs hanging gracefully down for more than a couple of feet. Even at their advanced size and age the trees were by no means cramped for room, although when viewed from the opposite side of the lake the trio seemed as if but one gigantic specimen. For small places such a method of planting would never do; although even then it is wise policy to have only a few well laid out clumps in preference to single specimens dotted about here and there, and which latter are hard to place so that they may look well and be in keeping with their surroundings.

To those with plenty of ground space I would say plant no, or very few, single specimens, but, instead, clumps or masses, particularly of weeping, fastigiate, or brightly tinted trees and shrubs, and these, if well arranged, will afford an infinitely greater amount of pleasure than single subjects, be they dotted about ever so thickly, and planted with more than a usual amount of care and attention.

That there are exceptions to the effect produced by single specimens generally will readily be seen from the accompanying illustration of a well-developed example of the Weeping Ash. This tree ramifies to a great extent, and is, perhaps, the best weeping tree for using as a single specimen, few others making a more interesting and distinct picture.

All over the country are to be found fine old trees of the Weeping Ash, such as shown in the illustration. Kent is abundant in weeping forms of the Ash, and a drive from London to Chislehurst is well repaid by the quantity of these as well as other rare ornamental trees that are to be found in the gardens and grounds. A tree of the Weeping Ash hardly 30 feet high might be pointed out, the spread of whose pendent branches is 50 feet in diameter, and that is not unusual when the tree is growing on rich damp loam. The golden form of the

Weeping Ash (*F. Excelsior aurea pendula*) is not desirable, at least I have never seen a specimen that would not have been the better of removal, so far at least as the appearance of the surroundings were influenced by it.

To sum up concisely, I may say that, generally speaking, weeping, upright, or other peculiarly-habited trees and shrubs look better in clumps of irregular size if the grounds are boldly laid out, while at the same time a few species, such as the Ash in question, which ramify extensively can with all appropriateness be used as single specimens. W.

#### A FAMOUS TREE.

(*PTEROCARPA CAUCASICA*.)

THERE is a special beauty about *Pterocarya caucasica* when full of foliage and covered with its peculiar catkins that makes one wonder why it has not been more extensively planted, especially as it seems to have been introduced from Southern Russia quite 100 years ago. I think, however, that the reason for its absence in the majority of gardens may be traced to the fact that it is one of the earliest trees, either indigenous or exotic, to push its foliage, and that both young leaves and catkins are often cut by spring frosts. The catkins, both male and female, are quite destroyed (this was the case this year), and, although young foliage breaks away again, the fact of the susceptibility to frost probably led to its exclusion in future planting operations under the impression that it was really more tender than is actually the case.

The subject of the accompanying illustration—which, so far as I can gather, is by far the largest specimen in England—was probably planted in the early twenties. I thought at one time it was considerably older, but the experience of the last ten or twelve years has shown that it grows and develops in size both of trunk and branch at a great pace. I know of no tree whose root-action is at once so vigorous and so extended, and it should never be planted in near proximity to anything that is likely to suffer from its underground activity. Strong fibres have been found quite 30 yards from the stem. Our tree was, unfortunately, planted on a site not far distant from fruit tree, flower, and Vine borders, necessitating the cutting of rather deep trenches to prevent its roots encroaching on these borders. Careful measurement gives the height of the tree 45 feet: girth of stem, 3 feet from the ground, 17 feet; and spread of branches (circumference) nearly 110 yards. I had not heard of the tree ripening its seed in England, and was unable for some years to procure a seedling, but in the summer of 1899 a tiny plant was discovered in a warm corner. This has grown into a healthy little specimen, and will be planted this autumn in a prominent position to perpetuate the memory of the parent tree, for this is doomed at no very distant date. Several of the largest branches are nearly horizontal in growth, and the strain, especially when they are clothed with foliage and catkins, is naturally very great. The tree is propped in all directions, but I fear some day the weight will prove too much for the props.

*Claremont.*

E. BURRELL.

#### NEW CARNATIONS.

A VISIT to Edenside (Mr. Douglas' nursery) in July was quite sufficient to prove that, good as are the Carnations already in commerce, better are yet to come, and amongst the new ones being sent out for the first time this autumn the following attracted my notice. I

might say they are all show flowers, but there is nothing miffy about their growth, and no doubt they are of equally good, if not better, constitution than those we have already had from the same source.

Lord Justice first attracted my notice, a fine fancy after the style of Queen Bess, but an improvement on that flower, heavily marked scarlet and lilac on deep yellow ground; Ormonde, another good flower, bright red margin; Seymour Corcoran, a new self of amber colour, of fine shape and form. Amphion took my fancy as one of the best of the new ones, a very lovely flower that can be highly recommended. Another good flower was Countess of Verulam, with a heavy margin of scarlet, an excellent bloom; and Gronow, very perpetual, that will make a stir on the exhibition bench if I am not mistaken. There were many others, but these I especially noted.

H. E. MOLYNEUX.

*Brantwood, Balham, S.W.*

[We are sorry two or three varieties were incorrectly spelt in Mr. Molyneux's excellent article last week on "Border Carnations." "Huella" should be Tenella, and for "Lanzan" read Lauzan.]

#### CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

#### ROOT PRUNING OF FRUIT TREES.

[To THE EDITOR OF "THE GARDEN."]

SIR,—I shall be obliged if you will answer the following questions re root pruning of fruit trees: What is the effect of root pruning (1) on Pear and Apple trees growing in the open or garden walls? (2) Peach and Nectarine trees under glass? Do you expect good crops of fruit the following year after pruning, and do you expect the fruit to be as good in size and quality? PRUNUM.

The question is frequently asked as to what is the value of root pruning, and when it should be done and how. Though a simple matter, the work to be a success needs a certain amount of care. It is also asked, Can good crops be expected the season following root pruning? And we say yes, certainly, but especially in later years the effect will be seen in better crops and finer fruit. Of course there are failures which often occur by what may be termed mutilating or crippling the roots. If this is done so that the trees suffer it stands to reason the crop will fail. It is foolish to cut the roots so severely as to injure the trees. Trees properly planted and afterwards transplanted if necessary are a mass of fibrous roots, and such trees do not require root pruning. It is those trees with a few strong roots and few fibres that require taking in hand. That transplanting is as effective as root pruning, and though such trees are never root pruned, a great deal depends upon the growth, the soil, and other details. Trees not pruned too hard but allowed to grow freely and crop well do not need root pruning; it is the barren ones with strong top and root growth that need it.

Trees planted in rich soil or soil heavily manured at the start are most likely to need root pruning. Of course this means food, but not in a young state, before they attain fruiting size, should quantities be given at the roots. Take young Peach and Nectarine trees under glass, the question is asked, What is the effect of root pruning? If the trees are not more than ten years old I would advise quite different treatment to Apples and Pears in the open; at the same time I do not advise root pruning for old trees under glass. It is far better to grow young trees than old ones.

(1) Apples and Pears on open garden walls are more readily root pruned than trees in the open, as the wall keeps them within bounds on one side of the roots, and by making a semi-circle round the other portion the work is not difficult. There is no better time to prune than now, that is, before the leaves fall, say from the end of September till the end of October. I have done this work even up to the end of the year in mild seasons, but by doing the root pruning now new fibrous roots form before the winter. The effect of root pruning on gross trees causes fruit buds to form freely next season, it prevents so much useless or non-fruiting wood, and encourages a more fruitful growth. The effect is less seen next season than in later years. I do not practise root pruning with trees fruiting freely, and with young trees, say, from two years to six years, I have found lifting and replanting more effective than root pruning, as young trees at the start are often inclined to make gross wood. They should, of course, be carefully lifted at this season just before the leaves fall and carefully planted. We see how well young trees in fruit nurseries succeed; there the trees are frequently transplanted, and this induces fibrous root growth. In root pruning it is important to get a good workable space, say, for instance, at least 18 inches of room in the trench, or even more with older trees. With young trees at least 3 feet space should be allowed from the wall to the trench. In removing surface soil it is advisable to save this to place next the roots that are cut, make firm the soil, carefully spreading out fibrous roots as the work proceeds. With older or large trees it is not necessary to do the work in one season, half may be done now, the other next year. It may be advantageous in poor soils to add new of a loamy nature, or such materials as bone-meal, wood ashes, or burnt soil.

(2) We now come to trees under glass, and here the work is equally important; indeed, young trees under glass often need root pruning, and much the same advice is applicable. With young trees I would advise transplanting, and in lifting or transplanting the roots must be cut so that in a measure transplanting is root pruning, but by simply root pruning the Peach and Nectarine there is no loss of crop the following season. The work is best done before the leaves fall or just at that period, and great care should be taken to preserve the small roots; large, coarse roots should be shortened back to within 18 inches of the tree. Replace these roots in an upward direction, and make them firm as the work proceeds. By doing the work now there need be no loss of crop or size of fruit next season. If the soil is dry and the roots thoroughly wetted keep at least 3 feet from the stem of the trees with forks and spades. It is an easy matter to get well under the trees and cut the strong roots, but great care should be taken that the soil is well filled in and made firm or sinking will follow. After the lifting or pruning trees should be kept as cool as possible, and with trees bearing much foliage it is a good plan to damp overhead daily for a time; this prevents the bark shrivelling. Do not allow the borders to get sodden, but the roots should be kept moist.—G. W.]

#### ROSA LEVIGATA.

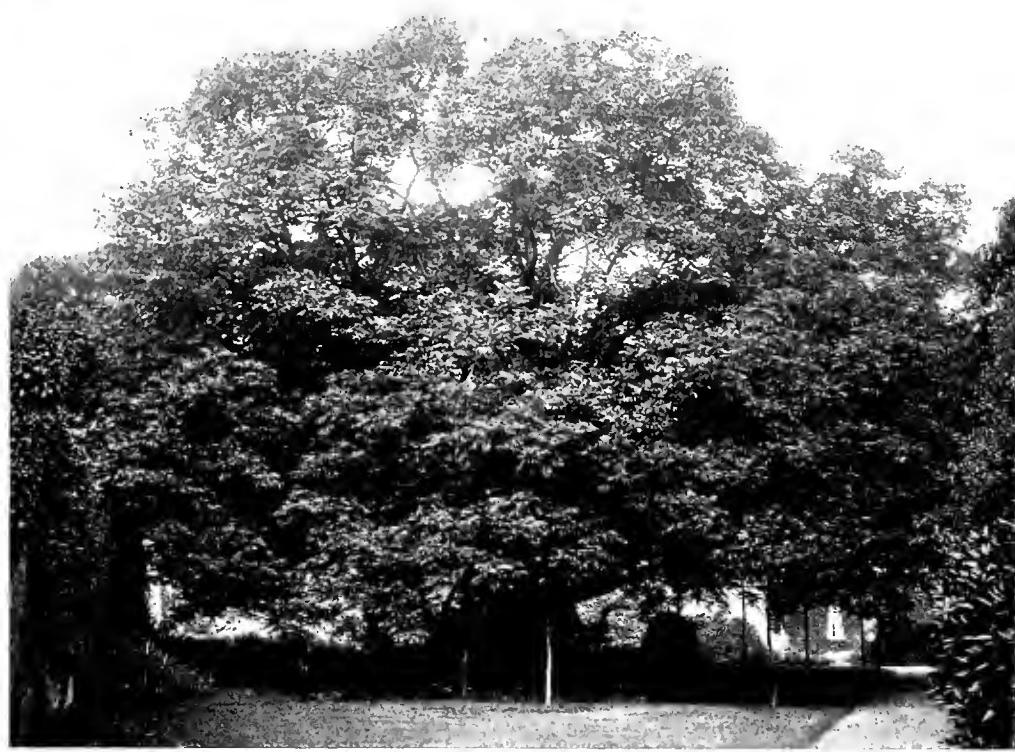

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Mr. W. Botting Hemsley's most interesting "History of the Cherokee Rose," a synonym for Rosa levigata (page 167), is the first detailed account of this lovely species that has met my eye. Much confusion has been caused by its numerous synonyms, and it is to be found growing under the names of R. levigata, R. sinica, the Cherokee Rose, and the Camellia Rose. It is probably not sufficiently hardy to flourish in the colder parts of this country, but in the south-west it succeeds admirably and presents a charming sight in May when covered with its great single white flowers. Besides having been grown so long and extensively

in Georgia as to earn the name of Cherokee Rose, it is common in the West Indies, Madeira, and some parts of India. Being thus widely distributed in various parts of the globe, it is not surprising that there are different forms of this Rose, some of which are superior to others. The finest I know came as a small plant from the North-west of India. This is growing at Kingswear, South Devon, and has thriven amazingly, being well covered with foliage to the base, which has a spread of 30 feet, while its highest shoots are 35 feet from the ground. It bears flowers which average 5½ inches in diameter, but some blossoms that I have measured were 6 inches across. An excellent illustration of this Rose, slightly reduced, from a drawing by Mr. H. G. Moon, appeared on page 29, vol. IX. A few miles distant a plant of the so-called Camellia Rose, which was brought from the Riviera, is growing, and I compared the flowers of this with those of the Kingswear Rose when both were in bloom, with the result that I found the blossoms of the latter to be nearly half as large again as those of the former, thus showing

the south of it, was flat, and on rapping this place it was found to be hollow. I think the outer bark was never cracked; but on slitting it up I found that it bridged over a space 1 inch, 2 inches, or 4 inches wide when the wood was bare, and was in process of being healed over by the advance of a callus from each side. This healing seemed to go on slowly till the wound was exposed to the air and the cavity a home for vermin and rot, but after the slitting up the callus grew freely and the tree improved in health. If this be of the nature of what you call sunstroke—in spite of the bark not cracking—can an explanation be given of the action of the sun, whether in killing the bark or the cambium or in stimulating the growth of a previously overshadowed tree? I have seen at least one case of the same thing in a transplanted Birch. STEPHEN A. MARSHALL.

[We presume that the cases referred to by you are the same as sunstroke, despite the bark not cracking. This cracking may be more pronounced in some trees than in others. As this question of sunstroke is at present as it were in its infancy,

THE FAMOUS PTEROCARYA CAUCASICA IN THE GARDENS OF CLAREMONT, ESHER, A RESIDENCE OF H.R.H. THE DUCHESS OF ALBANY.

the difference that exists between forms of the same species. Many cuttings have been struck from the Kingswear Rose and given away when rooted, but these have shown little vigour and take a long time to grow into good plants. It is quite another matter when this Rose is budded on the R. polyantha stock, as it then makes rampant growth and becomes a large plant in a few years, often blooming the second season, whereas cuttings rarely flower under four or five years. S. W. F.

#### "SUNSTROKE" OF TREES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I have in recent years transplanted out of copse woods a number of seedling wild Cherries, 15 feet to 25 feet high, and have been much puzzled by the stems of several of them showing signs of failure, which I think may be akin to what is described as "sunstroke" in your issue of the 6th ult.

The first thing I saw was that a stripe up the trunk of the tree, generally, but not always, on

we shall doubtless learn more of the matter later on, but at present it appears to us that the mischief originates in the cambium and in the more sensitive inner bark adjoining, as these portions are naturally more readily affected than the rougher bark on the outside.—ED.]

#### BULB GROWING IN ENGLAND.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Everyone with the interest of the country at heart must be glad to learn by the editorial article on page 189 of THE GARDEN that bulb growing is making such rapid strides in that portion of England which seems intended by Nature to compete with the neighbouring country of Holland viz., the Eastern Coast. With the general outcry concerning the decadence of agriculture, it is quite refreshing to read of something likely to yield such good results, for we have certainly for many many years paid far more to the foreigner for bulbs than we need have done if their culture had been seriously taken up in this country. That

home-grown bulbs are far more easily obtainable than they were a few years since has been several times brought under my notice of late, and that they may continue greatly to increase is my fervent wish.

In conjunction with the editorial article in THE GARDEN, the following sentence in the preface to the "New Guide to Herbaceous Plants," just issued at Kew, affords pleasant reading: "Mention must be made of the Kew collection of bulbs. These, though largely used to produce a decorative effect in the spring, are in great measure of botanical interest. They have for the most part been grown at Kew since 1886 from a small original stock by the same methods as are employed in Holland. At the beginning of summer they are lifted, harvested, and planted out again the following autumn." Anyone accustomed to see the spring display of bulbs will agree that they are equal to the best Dutch samples, and that they have been grown so long at Kew will surprise many, and at the same time prove that there is no insurmountable difficulty in the matter.

## GARDENING OF THE WEEK.

### KITCHEN GARDEN.

#### CABBAGE.

**A**LTHOUGH one of our commonest vegetables, the Cabbage is probably the most useful of all, as there is no season of the year if a careful and judicious system of treatment is practised when a good supply may not be had. In my opinion there are far too many kinds of Cabbage cultivated, many of which cannot be relied upon. I have made very extensive trials during recent years, and I have found nothing to equal or nearly as good as a true stock of Ellam's Early for the first planting; it is, as its name implies, very early and of excellent quality, the heads quite large enough for general use, and it seldom runs to seed. If I were to be restricted to one variety I should unquestionably keep this. Sutton's Flower of Spring is also excellent but later, and the head larger; it is of good quality and a fine market variety. Carter's Model is the best kind I am acquainted with for exhibition purposes during spring and summer; it is of perfect shape and just the right size, but the seed must be sown very late or a large percentage will bolt.

To ensure a succession of good heads several plantations in various parts of the garden should be made at this season. If the ground has been heavily manured for a previous crop it will be quite sufficient, unless the land is of a poor and hungry nature, then another good dressing should be given, and nothing is better than good farmyard manure. Mould up the plants well before severe weather sets in as it is the stems of the plants which are the most likely to be damaged. A large brown grub often eats off the autumn plants just under the surface; these should be searched for and destroyed, and the vacancies made good. Prick out a good batch of the smallest plants in skeleton frames or on a south border where they can be protected; they will often prove serviceable after a very hard winter. Coleworts, owing to the frequent rains, have made much progress, and the earlier plantings will soon be fit for use, but the later ones will probably prove to be the most useful. In many gardens a supply of

#### FRENCH BEANS

has to be kept up all through the winter. Frames filled from the late sowing should now be placed on the south border, but abundance of air must be admitted whenever the weather will permit. If covered with protecting material when frost is likely to occur these will continue to bear for a long time yet.

Seedlings from seed sown in heated pits will now be well above the soil, and the seedlings should be

carefully nursed, but at the same time endeavour to promote a stout sturdy growth. Fire-heat should only be given during cold nights. Earth up the plants to the seed leaf with light soil which has been warmed. Make another good sowing of the variety Canadian Wonder in 8½-inch pots; these should be well drained and filled with a light compost, raise the plants in a slight heat, but do not allow them to become drawn.

E. BECKETT.  
*Aldenham House Gardens, Elstree, Herts.*

### THE FRUIT GARDEN.

#### STRAWBERRIES FOR FORCING.

THE first point towards success in forcing Strawberries is to grow the plants well in the preceding season, and no subsequent treatment will compensate for defects in this matter. The plants at the present time should be developing healthy sturdy foliage; soft flabby foliage is the result of a compost too rich in humus, and is not desirable, as was pointed out when directions were given for potting. Watering must be attended to, and when it is wanted give thorough soakings, frequent driplets being almost useless. Keep runners regularly removed, and remove also side growths from the crowns, thus confining each plant to a single bold crown, for it is better to have a few strong flower spikes than a greater number of weakly ones. Should the surface soil become crusted, lightly disturb it with a pointed stick, at the same time clear away weeds. Allow the plants ample space in a sunny position to freely develop their foliage. We are trying The Laxton in a limited way, and the plants look remarkably promising, and appear to have a strong constitution. It will, however, have to be of extraordinary merit if it eclipses Royal Sovereign.

#### THE ORCHARD HOUSE.

Structures containing late Plums, &c., should be freely ventilated during the day time in fine weather. Admit air at night and keep the soil moist, but guard against an excessive moisture either in the soil or atmosphere, as it would be liable to cause the fruit to split and spoil the flavour. Such late Plums as Coe's Golden Drop, Reine Claude de Bavay, and Ickworth's Imperatrice will remain in good condition and considerably lengthen the Plum season if carefully gathered when ripe and placed between sheets of tissue paper in shallow padded boxes, and stored in a dry, cool room. Apples, Pears, Plums, &c., should as soon as they are relieved of fruit be moved out of doors and stood upon a firm bed of ashes or upon slates in a sunny position, where their roots should be protected from heavy rainfall.

#### POTTING THE TREES.

Trees with closely-confined rooting space, as pot sorts must necessarily have, quickly exhaust their soil, and those that need repotting should be attended to once their foliage is ready to fall. In the case of trees which it is undesirable to shift into larger pots, reduce their balls of soil sufficiently to admit of a layer of fresh compost being placed around them. This can be done with the help of a small hand fork, the outside roots being disentangled and shortened by a clean cut. Ensure perfect drainage, but do not use crocks needlessly, and ram the fresh compost firmly. This should be in a tolerably dry state, and consist of about three parts strong maiden loam and one part of dry horse manure, moderately mixed with crushed mortar rubble, bone-meal, and soot. Those trees that do not require to be repotted should have all the surface soil that can be removed cleared away, and be firmly top-dressed with fresh compost. Young trees that occupy small pots and have an abundance of roots should be shifted into pots one size larger. Carefully turn them out and slightly disentangle the side roots by pricking over the outside soil, and shorten the strongest so that more fibrous ones may be formed. Pot firmly, as advised for older trees, and give sufficient water to moisten the soil through. In purchasing trees it is advisable to select those that are established in small pots, say, about 9 inches in diameter, but

if trees are chosen from open quarters place them in as small pots as their roots can be conveniently got into, and after potting plunge the pots into a bed of ashes or similar material, so that the roots do not suffer from fluctuations of atmospheric conditions, and are encouraged to make growth before the sap is dormant. The following are excellent dessert kinds suitable for the orchard house: Transparent Gages in variety, Oullin's Golden, Golden Esperen, Jefferson, Kirke's, Reine Claude de Bavay, Coe's Golden Drop, and Ickworth's Imperatrice.

T. COOMBER.

*The Hendre Gardens, Monmouth.*

### INDOOR GARDEN.

#### PRIMULA SINENSIS.

THE plant should be removed from the cold frames to a light and airy structure where they can be protected against frost and damp. Wash the pots, and set the plants well apart to allow sufficient light and air to pass amongst them.

#### HUMEIA ELEGANS.

As the pots become full of roots pot on the plants, using a rich open compost of loam, dried cow manure, and charcoal. Thorough drainage is indispensable. Having tender roots great care must be taken in potting. After the plants are established encourage them to make free growth by giving plenty of water. These plants when kept too dry at the roots during winter are sure to be attacked by thrip and spider, which is fatal to their well-doing. A cool airy house or pit where the plants can be kept near the glass is the best position for them.

#### FUCHSIAS.

Cuttings that are rooted should be placed singly in small pots in a mixture of loam, leaf-soil, and sand. Keep them near the glass in a warm, moist atmosphere, to encourage a short jointed sturdy growth. Many of the newer varieties need but little stopping or training. A neat stick should be placed to the leading growth. Green fly and red spider are great enemies to the plants, but with the use of the syringe they may be easily prevented. Another batch of cuttings may be put in for succession. Heliotropes and Lantanas require somewhat similar treatment.

#### ACHIMENES

that have passed out of flower should gradually have less water as the foliage and stems show signs of decay. Remove the stems as soon as dead and store the pots upon their sides in a warm, dry place, where no moisture can reach them until the time of starting again. Later batches should be given liberal supplies of water, with frequent applications of weak liquid manure.

#### FREESIAS.

The earliest batches will now require the support of neat sticks. Take care not to place them too near the bulbs. Freesias will not stand forcing, and it should not be attempted until the flower spikes appear. Well ripened bulbs potted early, and kept near the glass in a light position where frost is excluded, will come into flower early in December. Watering must be done with great care, and when the pots are full of roots weak liquid manure will greatly assist them.

#### ROMAN HYACINTHS

may be potted in successive batches, so that a continuous supply may be secured. The early batches in frames that are showing buds may be removed to a forcing temperature, where in a very few days they will come into flower.

Various bulbs that are plunged in cocoanut fibre or ashes should be examined occasionally, and as the tops begin to show remove the pots to a frame and subdue the light for a brief period, allowing them to progress slowly until they are wanted for forcing. The application of heat depends on the time the different bulbs are required to flower Narcissus, single Tulips, and single Hyacinths take kindly to forcing.

## THE FRUIT GARDEN.

### GRAPES FOR MARKET.

**G**RAPE growing for market has of recent years made rapid strides; within easy reach of London by road and rail there are now numerous nurseries whose chief and, in some cases, only culture is that of the Vine. The accompanying illustration gives a good idea of the size of a typical viney in a market nursery, and also of the heavy crops that the grower annually obtains from the Vines, such crops that many gardeners would never dream of allowing their plants to bear year after year. With good and liberal treatment, however, it is astonishing what large quantities of good Grapes the Vine will bear for many years. By allowing the leaves to remain on the ground after they have fallen an excellent purpose is served, namely, that of preventing the dust from rising. It is common knowledge that if dust settles upon ripe Grapes it is impossible to dislodge it without destroying the appearance of the bunch, because of the delicate bloom that covers the surface of the berries, and which is so easily disfigured. The most popular varieties of Grapes with market growers are Gros Colman (black) and Cannon Hall Muscat (white).

### INSECT PESTS AND THE FRUIT CROPS.

#### WAKE UP FRUIT GROWERS!

ONE would think, judging from the information given of recent years respecting injurious insect pests, and the improved appliances in the way of insecticides and sprayers which have been introduced, that the foes would be entirely eradicated by this time, or else so reduced as to be of no account. But such is not the case. Either by the supreme ordering of Nature, or else through the neglect on part of fruit growers to take advantage of the facilities offered them by manufacturers and scientists, insect pests are just about as numerous as they ever have been. They come in greater or lesser numbers according to climatic conditions, and commit their ravages just as they did a generation ago, and are treated by fruit growers in much about the same philosophical way. Here and there one meets with a market grower who sprays his trees and wages war against his natural enemies, but the majority do not, and they accept the attacks in much the same light as they do an early spring frost or a spell of drought, as being matters over which they have no control.

While this spirit prevails insect pests will never be eradicated, and the men who make a fair attempt at it are sorely handicapped by the lethargy of the so-called philosophers who do nothing. This matter, like many others dealing with land cultivation in this country, is suffering from the want of combination. What is the good of a man spraying his trees and taking steps to keep down insect pests when his neighbour allows them free play. It is hard on the striving individual, but he is the victim of circumstances, because, unfortunately, there is no law which compels fruit growers to observe the importance of cleanliness.

With bright exceptions here and there the majority of fruit growers seem to look at the matter in this light. They have certain opposing forces to deal with, including spring frosts, cold winds, want of rain or too much of it, and insect pests. Sometimes Nature deals kindly

with them, they suffer through none of these causes and are thankful, but if on the other hand the fruit crop wholly or partially fails through unfavourable weather or living enemies they regard themselves as helpless to avoid the catastrophe.

Whatever may be urged against the climate this season—and there have been just reasons for complaint—fruit growers generally have not suffered through the ravages of insects nearly so much as in former seasons. The reason is obvious. The weather, which has been against the fruit, has not been favourable for insects, and so, for the fruit grower, some good has come out of evil. Cold nights have been against the foes, heavy rains have dislodged them from the trees, and the appearance of hardy fruits, such as Apples and Pears, is fresh and clean, though the season is nearly at an end. In the case of Damsons and certain Plums I must make exception, for aphis has played havoc with them. Early in the summer a cold easterly wind blew for days together, and the country people in my district said they knew what would happen.

They regard an east wind as the originator of blight, or they fancy that it is borne on the wings of the breeze from distant regions, but somehow it generally comes when these conditions prevail, and in spite of copious rains the leaves of Damsons and Plums have been curled, distorted, and blackened by the presence of the sticky pests. When the trees were "struck" fruit had set, and timely spraying with an insecticide might have saved the crop, but the opportunity passed by, the tiny fruits turned sickly and yellow, and then fell to the ground, along with all hopes of a crop.

In the case of the Apple crop, which is occupying particular attention, there are four pests that affect growers more than others, viz., American blight, Apple aphis, winter moth caterpillar, and the grub of the codlin moth. Fruit growers as a rule are afraid of the former, as they have cause to be. In the case of their young trees they keep a sharp look out for the pests, but for some unexplained reason American blight is allowed to flourish undisturbed on the gnarled branches of the old orchard trees, whose moss-covered limbs also provide harbourage for numerous other pests. The growers say that the old trees do not pay for cleaning. Perhaps not, but they forget that the white woolly matter which protects the American

blight is borne on the breeze, and from the old trees, which in themselves are not worth cleaning, the evil is spread to valuable young specimens in the vicinity.

So far as my observation goes aphis on Apple trees seems to be on the increase. This season it has been a source of trouble, and appeared after the spell of cold wind already referred to. It shows a preference for young newly-planted dwarf trees, and many plantations have suffered considerably. Little harm has been done where the trees were sprayed at once with a solution of quassia, but some growers neglected this operation, and in these cases the leaves that have not fallen are black and disfigured.

I am inclined to think that the winter moth caterpillar is not such a dreaded foe of the Apple as some people would have us believe, because if such were the case the damage done would be considerably worse than it is. In many instances this summer I have seen Thorn hedges simply defoliated by living masses of wriggling caterpillars, and yet the Apple trees in the neighbouring orchards were not seriously affected. All the same we know what the pest is capable of, and it is to the interest of the fruit grower to keep it down, but this is only half done. People used to grease-band their trees at one time, but this has been almost discontinued as being something less than half a measure, and some growers spray with Paris green, but I have never seen anyone yet turn the nozzle of his sprayer on to the hedgerow round the orchard, though thousands of caterpillars were fattening themselves there, and the place was a veritable nursery for the increase of the pest. It seems a useless operation to spray fruit trees to destroy a pest while the same thing is allowed to increase in thousands all round.

Just now the market is pretty well supplied with grub-eaten Apples. The growers prefer to call them "windfalls," because it sounds better I suppose, but if they are looked over it may be observed that the majority of them have the tell-tale hole, bored by the codlin moth caterpillar. This pest is the great bane of the Apple crop, but it is not a curse in every sense of the word. Every writer on fruit culture advises the timely thinning of Apples, both for the sake of the tree and also the remaining fruits, and, with a few exceptions, the advice is promptly ignored by Apple growers.

HOUSE OF GROS COLMAN GRAPES IN A GREAT MARKET NURSERY. THE GRAPES ARE RIPE, AND THE LEAVES LEFT WHERE THEY HAVE FALLEN TO PREVENT DUST.

The codlin moth grub mercifully does the work that growers cannot find in their hearts to do, though they will pick up the bored fruits and send them to market. When Apples are plentiful, as is the case this year in many districts, the ravages of the caterpillar in question are not felt to any great extent, but in a season of comparative scarcity, when it is desirable that every fruit should be kept on the trees as long as it will hang, the foe reveals its presence, and Apples fall just the same as if they were abundant. It is at such times that the grower has reason to regret that he took no steps to circumvent this persistent foe. But he probably forgets all about it before another season, and with these and other insect foes the fact remains that no concentrated effort is made to get rid of them, and until this is done it is not likely that there will be any material reduction in their numbers.

G. H. H.

## THE INDOOR GARDEN.

### CENTROPOGON LUCYANUS.

**F**OR those who are fond of winter flowering plants this Centropogon, which is a hybrid between *C. fastuosus* and *Siphocampylus betulifolius*, can be recommended as a most useful one of this class. Its flowers are produced over several months, from November onwards. They are tubular, rosy carmine in colour, and freely borne on short spurs along the current year's growth. *C. Lucyanus* was raised as long ago as 1856 by a French gentleman, M. Desponds of Marseilles. Amateurs should not find the least difficulty in cultivating it, providing they are able to accommodate it in a warm house. By warm house I do not mean a stove, but simply one having a temperature of, say, 60° at night. Cuttings will be plentifully produced in February if the tops of the old plants are cut off after flowering. They also root readily under the following treatment: Let the cuttings be 3 inches or 4 inches long, and if possible with a heel of the old wood attached, although this is not absolutely essential; place them several in 4½-inch pots filled with a light sandy soil under a bell-glass or propagating frame in a warm house. Every morning the interior of this glass covering should be removed and wiped quite dry, otherwise the moisture that has collected will be very liable to cause the leaves of the cuttings to decay and probably will also saturate the soil. This may seem a small precaution, but it is a very necessary one.

When well rooted they should be placed singly in 3-inch pots and taken out of the propagating case. As they have somewhat tender roots a light friable soil is necessary, and it must not be made too firm. A mixture of equal proportions of rough fibrous loam, peat, and leaf-mould, with a fair addition of silver sand, is suitable. Ample drainage is also essential. If the plantlets are kept near the glass their growth will be all the stronger and healthier. A moist atmosphere should be maintained always on sunny days, syringing the plants and well damping the floors, &c., when the house is closed in the afternoon. As soon as the small pots are well filled with roots repot their occupants into 4½-inch or 6-inch pots. Unless the plants are exceptionally vigorous I would prefer to make use of the former, and for this reason. As mentioned above *Centropogon Lucyanus* is by no means strong rooting, and if it should happen that the 6-inch pots were not well filled with roots, an occurrence not at all unlikely, the soil would most probably soon become unwholesome if very careful watering were not practised.

During normal summer weather the *Centropogon* may be grown in a cool pit, providing that this is closed early in the afternoon, so as to make the most of the solar heat, and well moistened. On the approach of cold weather replace the plants in the warm house, and they will before long begin to show flower. When fully in bloom remove to the conservatory, where they will prove bright and cheerful throughout the dull months. A. P. H.

### TIBOUCHINA MACRANTHA.

No one possessing a cool greenhouse should be without this valuable flowering climbing plant. It blooms throughout the greater part of the year, even during winter. The large, richly coloured blossoms of a deep violet-purple are very freely produced, although they do not remain fresh for so long a time as could be desired. On the roof of a light cool house it makes a brave show. It usually succeeds best when planted out, as indeed do nearly all climbers; when grown in a pot its growth is not nearly so free and vigorous.

During the winter time less water is naturally required than in the summer, for growth is less active. It is very necessary to provide ample drainage for *Tibouchina macrantha*, as plenty of water is required during the growing season. The want of effective and sufficient drainage is often the cause of failure to grow greenhouse climbers successfully. The soil obviously cannot be examined and the crocks readjusted if necessary as with pot plants, so that it behoves one to attend to this important matter at planting time. The subject of this note may be increased by inserting cuttings in summer of wood that is partially ripened, placing them in sandy soil under a bell-glass in a warm house.

A. P. H.

## MISCELLANEOUS.

### NOTES FROM SWANSWICK

**E**VEN in our old garden of unregretted memory—it was exactly the sort of enclosure, stuffy and yet draughty, which Roses most dislike—there were several Roses which did remarkably well. Mrs. W. J. Grant, which I much prefer to call by the pretty name of Belle Siebrecht rather than by the ugly and prosaic name before-said, was one, and Mrs. Sharman Crawford another, while there was a beautiful red Bourbon on a wall, the name of which was not known, but which I think may have been Mrs. Paul. It had been maltreated after the usual way of the awful "jobber," by being clipped all over, old and new wood alike, with his murderous secateur, but when it recovered and sent up some strong bright red shoots we got masses of bloom from it, great full-breasted flowers, with thick petals and of fine colour—a rich crimson-pink. Does this answer the correct description of Mrs. Paul? Roses seem to change their character when misunderstood and badly treated to an extraordinary extent, and only to come back to it slowly. Like another of

THE GARDEN correspondents, we found Kaiserin Augusta Victoria do nothing but make wood, and it is doing the same thing here, where a pillar plant between 4 feet and 5 feet high has only had one miserable bloom. The two pink Roses I first mentioned are doing grandly, and have had many flowers of perfect shape on quite small bushes. Grüss an Teplitz, in spite of being only turned out from a pot in spring, has grown immensely and flowered well. It is very thin, but a beautiful red, and the blooms die off neatly and respectfully and quickly. Some Roses never know how to retire gracefully. The white Clusters are simply horrible in this respect. It is hideous to see a tree some 20 feet high draped with wreaths of brown lumps, sodden and obstinate, and is almost too great a price to pay for the earlier brief beauty of the bloom-time. To Reine Olga de Wurtemburg the same remarks might apply as far as its behaviour here goes. I would not be without these four Roses on any account. Caroline Testout seems to be another thoroughly reliable bloomer, and, though its shape is not so aesthetic or pleasant as that of Belle Siebrecht—for its flowers are a shade cabbagy—still, it is very lovely, and not to be dispensed with.

The Mountain Ash trees have had a tremendous crop of berries this year, which brought first of all missel thrushes and then young bullfinches by the dozen to clear off every berry. Near here there are two trees growing within 50 yards of each other, and, so far as can be seen, absolutely

identical, even in size, and both with heavy crops. The birds have completely denuded one and have not touched the other. Why?

What a detestable weed Ivy can be in a place where it has been neglected. Seedlings of it are coming up by the thousand here, and the pale yellow *Meconopsis* is nearly as bad. The ordinary yellow *Coreopsis* has a firm footing, too, but is such a neat grower and persistent flowerer that its presence is seldom objectionable. It would be impossible to go over this garden without again remarking what observers have mentioned before—the way in which weeds caricature garden plants and try to follow up the deception. In the kitchen garden there are a number of Dahlias planted, just for this year and to save the roots, in a regiment equally spaced. While they were still small, the Sow Thistle, hugely indigenous, found out that it resembled them, and set to work to crowd up close to them and imitate them as nearly as it possibly could. Even now nearly every Dahlia has its closely adherent Sow Thistle satellite pretending to be part of it, and sometimes escaping detection. I am very ignorant of weed names, but there is a thing exactly like *Potentilla* that, similarly, only grows about where the *Potentillas* do. Only the Bindweed can find no affinity, but is so brazen it does not mind. No one seems to take much interest in *Oxalis*. I want to know whether *O. floribunda*, for which I have a great liking and which seems to me so very superior to any of the others as a garden beauty, should be planted in autumn or in spring, and none of the books tell me this. A clump of it has bloomed unceasingly since May, and the colour is a good gay rosy pink, much brighter and livelier than that of *O. rosea*, while the flowers are bigger and stay open better than those of any other I know. I am told the white *O. enneaphylla* is extremely good, but have not yet tried it. I mean to make a rather large planting of *O. floribunda* about and round some *Cistuses*. The latter are still quite small, and their flowers are just about the same pink as the *Oxalis* in question. The name I do not know, the original having been a find from a nursery garden, where it was anonymous.

Petunias have been a ghastly failure here in this sopping season. Five weeks ago they went all brown and rotten, and have never recovered. Last year they and the zonals were the only things that did not have to be perpetually watered, whence their measure of popularity, but their stickiness, smell, and excessive fragility of stem are all against them, and, since I never remember hearing anyone say they liked them, it is curious how they are, all the same, to be found in nearly all gardens.

M. L. W.

### THE PURCHASE OF ARTIFICIAL MANURES.

WHILE certain artificial or, as they are sometimes called, chemical, or light manures are, according to the leaflet recently issued by the Board of Agriculture, to some extent applied in autumn, it is in spring that farmers lay in the bulk of their supplies, and therefore it seems appropriate that a few suggestions should be offered at this season in regard to their use and economical purchase. There are three substances, and only three, that are valued in artificial manures, namely, nitrogen, phosphates, and potash. According, therefore, to the greater or less quantity of one or other of these substances the value of the manure will rise or fall. Some manures contain only one of these substances—for instance, nitrate of soda and sulphate of ammonia contain only nitrogen; superphosphate, precipitated phosphate, and basic slag contain only phosphate; and kainite, sulphate of potash, and muriate of potash contain only potash—while other manures hold two substances of value, as in the case of bones, which furnish both nitrogen and phosphates, or saltpetre (very seldom used, however, as a manure), which supplies both nitrogen and potash. Only one class of so-called artificial manure, namely, Peruvian or other similar guano, contains an important amount of all three substances.

In price lists, nitrogen is often expressed as

ammonia. The relationship between the two substances is, however, a very simple one, and need occasion no difficulty or uncertainty. 17lb. of ammonia always contain exactly 14lb. of nitrogen, or, what is the same thing from the farmer's point of view, 14lb. of nitrogen are the equivalent of 17lb. of ammonia. If, therefore, a sample of, say "Corn Manure," is offered as containing 4·5 per cent. of ammonia, this is the same as saying that it contains 3·7 per cent. of nitrogen. Sometimes, though not often, the figure is made to look more attractive by being stated as sulphate of ammonia, but this also need cause no difficulty, if it be remembered that 66lb. of this substance are equivalent to no more than 14lb. of nitrogen or 17lb. of ammonia. If, therefore, we take the above example, the figures mean one and the same thing, whether they are stated 3·7 per cent. of nitrogen, or 4·5 per cent. of ammonia, or 17·4 per cent. of sulphate of ammonia. But a manure merchant, who failed to effect many sales for a fertiliser, of ever so high-sounding a name, on a statement of 1 per cent. of nitrogen or 1·2 per cent. of ammonia, might be more successful with a certain class of buyer if he entered the nitrogen as equal to 4·7 per cent. of sulphate of ammonia, and yet the three figures all represent the same fact. Under the Fertilisers and Feeding Stuffs Act, 1893, the invoice must contain the minimum guarantee of nitrogen, stated as such.

Phosphates or phosphate of lime may also be entered in an analysis or price list in several ways, but as a rule this ingredient is either stated as above or as phosphoric acid. In an invoice, however, the statement must be made as soluble or insoluble phosphates, as the case may be. The relationship between phosphates or phosphate of lime, whether soluble or insoluble, and phosphoric acid is quite as simple as that between nitrogen and ammonia; 142lb. of phosphoric acid always form 310lb. of phosphate of lime, so that to convert the former into the latter one may multiply by 2·2, which, though giving an answer slightly above the truth, is quite accurate enough for all ordinary purposes. If, therefore, the analysis of a manure is returned as 12 per cent. of phosphoric acid, it is equivalent to saying that it contains fully 26 per cent. of phosphates. Similarly 30 per cent. of phosphates is equal to nearly 14 per cent. of phosphoric acid.

Potash usually exists in manure in the two forms of sulphate of potash and muriate or chloride of potash. It takes 94·2lb. of pure potash to form 174·2lb. of sulphate of potash, whereas the same amount of potash will form only 149·2lb. of the muriate or chloride. In the former case, therefore, to convert potash into terms of sulphate of potash, we multiply by 1·85, whereas in the latter case we multiply by 1·58. If, therefore, an analysis of, say, kainite is stated as 12·5 per cent. of potash, this is equivalent to saying that it holds over 23 per cent. of sulphate of potash; while muriate of potash guaranteed to contain 56·8 per cent. of potash is of about 90 per cent. purity. Just as a buyer may sometimes be led into purchasing a manure through its nitrogen being expressed as sulphate of ammonia, so may the contents of potash be made to look more attractive by being stated as sulphate of potash. In an invoice, however, the potash must be stated as such.

The rules for approximately converting the various terms into their equivalents may be thus summarised: To convert nitrogen into terms of ammonia multiply by 1·2; to convert nitrogen into terms of sulphate of ammonia multiply by 4·7; to convert phosphoric acid into terms of phosphates multiply by 2·2; to convert potash into terms of sulphate of potash multiply by 1·85; to convert potash into terms of muriate of potash multiply by 1·58.

Nitrogen and phosphates, and, to a less extent, potash, vary in effectiveness, and therefore in value, according to their source or origin. Nitrogen is never so effective as when in the form of nitrate of soda. It is not quite so active, and for some purposes not so valuable, when in the form of sulphate of ammonia, though under certain circumstances this somewhat slower action may be

regarded as an advantage. Nitrogen in, what is called, the organic form is in its least active condition, though here again the rapidity and effectiveness of action vary greatly. Nitrogen is in the organic form in blood meal, fish meal, bones, shoddy, &c., and yet as a source of plant food blood meal is more active than these other substances. It is claimed as an advantage for slow-acting manures that they last longer, which is true; but one applies manures not to last but to act. It is only where it is convenient to apply manure at somewhat long intervals, as in the treatment of orchards, that the more inert manures are worthy of much consideration. As regards phosphatic manures, it may be said that while soluble phosphates are all alike active, there is considerable difference in the value of insoluble phosphates. The insoluble phosphate of bone meal, for instance, is less effective, and for most purposes less valuable, than the insoluble phosphate of basic slag, precipitated phosphate, or even dissolved bones. Some of the insoluble phosphate of the last manure has once been soluble and has "reverted," and such phosphate is not much less effective than soluble phosphate. But raw bones as a manure have been longer known to British farmers than other forms of phosphate, and for this reason their price has kept relatively high.

#### THE MORE IMPORTANT MANURES.

*The purely nitrogenous manures.*—The most important are nitrate of soda and sulphate of ammonia, others in less general use being rape dust, blood meal, shoddy, &c. Other things being equal, nitrate of soda is specially suitable:—(a) For use in spring and early summer, as in the manuring of Hay, cereals, Potatoes and Mangolds; (b) for use on heavy land; (c) for use as a top-dressing; (d) for use in a dry district; (e) for use where immediate effect is desired. Speaking generally, sulphate of ammonia suits better:—(a) For use on crops that make their growth late in the season, for example, Turnips; (b) for use on light land; (c) for use on soil holding abundance of mild lime; (d) for use where it can be mixed with the soil (in contrast to top-dressing); (e) for use in a wet district. It is, however, often difficult to say for which of these two manures the conditions are most suitable; and then the question should be decided either by the relative cost of the substances, or by using a certain amount of both. If one of the organic manures can be bought at a cheap rate it may be used to some extent as an ingredient of a mixture.

Nitrogenous manures cannot be profitably employed on leguminous crops (Peas, Beans, Clover, &c.); and on a mixed crop of, say, Clover and grass, if the Clover is to be preserved against suppression, they must be used sparingly, if at all. They must also be used with caution on Barley, and especially so where a fine sample, rather than large yield, is looked for. Other crops, however, generally respond freely to the use of this class of manure. Nitrate of soda and sulphate of ammonia are apt to be lumpy, therefore the buyer should look carefully to the mechanical condition. Nothing should be applied that will not pass a half-inch riddle. Lumps larger than this will often kill plants with which they may come into contact. Nitrate of soda is generally offered on the basis of 95 per cent. of purity (= 15·6 per cent. nitrogen or 19 per cent. ammonia), while commercial sulphate of ammonia usually contains 97 per cent. of the pure article (= 20·6 per cent. nitrogen or 23 per cent. ammonia). Sulphate of ammonia is thus the more highly concentrated manure.

*The purely phosphatic manures.*—Of these super-phosphate and basic slag are the most important. The former is, speaking generally, more suitable for use under the following circumstances:—(a) Where rapid effect is wanted; (b) in spring; (c) for arable land; (d) for admixture with sulphate of ammonia. Basic slag is specially suitable:—(a) For use in autumn; (b) for use on grass land; (c) for use on land holding much peat or other vegetable matter; (d) for use on land addicted to finger and toe; (e) for use in orchards; (f) for admixture with nitrate of soda. Basic slag generally leaves little to be desired as regards

mechanical condition, providing the grinding be fine enough (80 per cent. through a No. 100 sieve—that is, 100 wires per linear inch, or 10,000 apertures per square inch)—should be the minimum requirement. Superphosphate is sometimes almost as dry and mealy as slag, but in other cases it is lumpy and sticky. Samples of the latter character are of reduced value, and should be avoided.

Superphosphate is of varying degrees of quality, the usual contents being 28 to 30 per cent. of soluble phosphate. Basic slag also varies in quality, the usual contents being 35 to 40 per cent. of insoluble phosphate.

Phosphatic manures are of special value in the manuring of Turnips, leguminous crops, Hay, and pasture. They are of less importance for Potatoes and Mangolds, and least of all for cereals. In the case of the last class of crops it usually happens that the plants are able to satisfy their requirements as regards phosphates, from the natural supplies in the soil, or from residues of former applications. Whether, on any particular farm, it will pay to apply a direct phosphatic dressing to a Corn crop can only be determined with certainty by means of a simple field experiment.

(To be continued.)

#### EDITOR'S TABLE.

##### A NEW PLANT FOR SHADY LAWNS. (*SELAGINELLA DENTICULATA*.)

I am sending you some small tufts, mostly composed of *Selaginella denticulata*, showing its adaptability for the purpose named. It grows freely in various parts of the grounds here, and has done so for many years, hence must be quite hardy. We can trace its origin to using some old potting soil when transplanting the choicer shrubs and trees. Up each side of the central walk in our conservatory are marginal boxes filled with the *Selaginella* in question. It is necessary to replant these boxes every few years so as to keep them green and fresh looking. We empty the contents on to our refuse soil heap, from which we get fresh soil for the purposes named.

*SELAGINELLA DENTICULATA.*

As is well known this *Selaginella* seeds freely when grown in a limited root space under glass, hence the whole heap of soil gets impregnated with the seeds as well as the small portions of the plant. In each position in which we have found it growing we can trace its origin to the way mentioned. Our soil is of a moist loamy nature, but as it overlays limestone is well drained. I am not foolish enough to suggest its use for lawns generally, but in the more shady portions of grounds its presence is sure to give some interest to many garden lovers whose tastes are catholic. It could easily be introduced in the positions I have indicated by cutting up into small pieces some straggling portions of the plant and sowing them where wanted. It would only be necessary to run a rake over the ground afterwards to let them in amongst the roots of the grass. As you may notice in the turf sent, the *Lycopodium* is outgrowing the grass, which in shady parts never grows very close.—H. J. C., Grinston, Tadcaster.

[A very interesting note indeed. Our correspondent sends a "turf" of it, quite mossy and most pleasant to the touch. This *Selaginella* is

well known, but those who do not know it can get some idea of it from the accompanying illustration.]

#### TUBEROUS BEGONIAS.

Messrs. Blackmore and Langdon, Tiverton Hill Nursery, Tiverton-on-Avon, Bath, have sent us a delightful gathering of tuberous Begonias, in both single and double varieties, all cut from plants growing in the open garden, and which were raised from seeds sown in January last of their own saving. Amongst the doubles are some lovely flowers : those of deep red, rich yellow, salmon pink, pink, buff-yellow, apricot, and white are particularly good ; the colours are distinct, and the flowers altogether refined and pleasing. We notice one most curious bloom—it is double, and the yellow petals are marked with green. The single flowers sent are very large and handsome, of rich colouring. We have seen nothing finer than Messrs. Blackmore and Langdon's scarlet singles. Enclosed also were blooms of a

NEW BORDER CARNATION MASTER F. WALL, cut from plants which have been flowering since the end of June. This Carnation is of a very pale blush, almost white, and is very sweetly scented. It apparently has a good constitution, and is a "non-splitter." Messrs. Blackmore and Langdon sent fruits of the new autumn-fruiting

#### STRAWBERRY ST. ANTOINE DE PADOUE.

These were deliciously flavoured, of a good size and firm, making a most acceptable dish for those who care for Strawberries in September.

#### ROSE MME. JULES GROLEZ.

Mr. Goodwin, The Elms, Kidderminster, sends a boxful of flowers of this beautiful and little-known Tea Rose. The colour is a pure rose, and the scent is powerful and delicious. The stems show that the Rose is very vigorous, the leaves large, serrated, and of a rich green, and the plant one to group in the garden.

#### EXOGONUM PURGA.

Messrs. De Graaff Brothers, Leiden, Holland, write : "We have much pleasure in submitting to your notice the flowers and foliage of Exogonium Purga, a very rare and beautiful climbing plant from Mexico, described in the *Botanical Magazine*, vol. iii., third series, fol. 42,811, by Mr. J. H. Balfour. The plant flowered last year with us all the summer, and did not finish until the frost cut its foliage down. Flowers are produced in large numbers, and the effect of a plant growing on a wall is magnificent. We hope these flowers will reach you in good condition."

[A very strong-growing and interesting plant, with dark leaves and long, warm purple flowers. Such a plant should be made note of by all who wish to add to their climbers.]

## NURSERY GARDENS.

### MESSRS. WEBB AND SONS, WORDSLEY.

SITUATED on the Kinver Hills the seed farms of Messrs. Webb and Sons—a short distance from Wordsley, near Stourbridge, where are the seed warehouses and glass department of this firm—form a brilliant bit of colour during the summer and autumn months, when masses of annuals are in flower. These are grown here in large quantities for the production of seed, and provide an excellent opportunity for comparing the different varieties, of noting their value and respective characteristics, such as habit of growth, profusion of flowering, time of flowering, &c., of noting the height to which certain varieties attain, and also of remarking the effect produced by such brilliantly coloured flowering plants as many of the annuals are—all of which particulars are of value to the good gardener.

It has for some years past been the custom of Messrs. Webb and Sons to invite a party of horticulturists to inspect their extensive seed farms and warehouses, and recently the annual visit was paid, Mr. Edward Webb and Mr. Stanley Webb kindly acting as guides to the party.

The Stocks made a bright display, and considering the season, which has not been to their liking, they were much better than one has generally seen this year. In most gardens this season there has been a very large percentage of singles. One of the most remarkable Stocks brought to our notice was the variety Celestial ; the double flowers are of sky blue colour, and produced remarkably freely. This will undoubtedly prove of value in gardens where these old-fashioned flowers are made use of, for its colouring is decided and distinct, a characteristic that is always of the greatest value in the flower garden. Vulcan, a late variety of a very branching habit, the flowers cherry red and freely borne, was also conspicuous. The Ten-week Stocks made a grand

there were Aurora, blue and purple ; Oriental, deep pink ; Sadie Burpee, white ; Primrose Queen (apparently the yellowest of yellow Sweet Peas) ; and Countess of Lathom, buff and pink. Stately Hollyhocks added to the general effect produced by these acres of flowers, and the Kinver air and soil apparently suit them perfectly, for they were uniformly good. Candytuft in masses of different colours, Mignonette, annual Lupins, and Canterbury Bells, all represented in great quantities and by good strains, gave further brightness and variety. The Shirley Poppies and French Poppies were very showy ; amongst the latter we remarked the varieties White Swan and Rosette, both double ; the last-named is a good pink. Carnations are cultivated here very largely, and amongst the enormous quantities of seedlings were blooms that had both good form and the best colours to recommend them.

Vegetables were equally well represented as the flowers. Cos and Cabbage Lettuces were remarkably fine : of the latter the best were All the Year Round, Summerhill, a very

A CORNER OF THE SEED TRIAL GROUNDS IN MESSRS. WEBB AND SONS' NURSERY AT STOURBRIDGE.

display : they were in great variety, the colours were good, and the flowers large. One variety of a primrose-yellow colour was most noticeable even amidst such a wealth of colour, and promises to prove of value.

The Nasturtiums made a beautiful show : the varieties were numerous, growing side by side in the trial beds, and of the most strikingly brilliant colours. Meteor (of the scarlets) and Golden King (of the yellows) appeared to be the best. All had come remarkably true from seed. We noticed a most unusual colour amongst them, one bed being filled with plants bearing flowers whose colour is perhaps best described as salmon rose. This is a good and novel colour amongst Nasturtiums, and when known will certainly become popular. The Sweet Peas it is almost needless to say made a rich display ; we were fortunate enough to see them just about at their best, and as there were 100 varieties under trial it will be understood that they made a striking show. All the best known and proved sorts were of course to be seen. Just to take a very few of the best,

crisp and sweet Lettuce, Wonderful, one of the best for exhibition purposes, and another resembling Model, but darker in colour and more compact. A most useful little Cos Lettuce is Wordsley Gem ; Monstrous White, another Cos variety, is large and of good colour. A splendid exhibition Cos Lettuce is one called Exhibition, and a selection from this promises to be even better. Messrs. Webb's collection of garden Peas is a most extensive one, and the trial of varieties severe. Talisman and Telegraph were yielding splendid crops, and the same also may be said of Senator. Besides the many named varieties grown, there are under trial a number of seedlings still unnamed of Messrs. Webb's own raising. Some of the most promising were of the following parentage : Daisy × Stratagem, Talisman × Royal Standard, Webb's Seedling × Sharpe's Queen, and a seedling × Peerless produced a splendid late Pea.

Such are a few of many interesting plants under trial for seed production in the Kinver seed farms of Messrs. Webb and Sons.

# THE GARDEN

No. 1612.—VOL. LXII.]

[OCTOBER 11, 1902]

## OWN-ROOT ROSES.

CORRESPONDENT writes as follows:

**A**—“I am most anxious to grow Roses on their own roots, and shall be obliged if you will tell me how to proceed to get them and the best varieties.”

To this we reply: Autumn is an excellent time to insert cuttings of the hardier groups, but the more tender Roses, such as the Tea-scented and Monthlies, root better in summer, though even these may be inserted now.

The following brief description of the ways generally adopted at this season of the year will, we hope, be useful to our correspondent and other readers of THE GARDEN.

Select a plot of ground in the open garden, not under hedges or walls as is so often advised. If the soil is heavy, trench it about 2 feet deep, incorporating at the same time plenty of drift sand or burnt garden refuse. If the soil be light, deep digging will suffice. No manure is required. What is wanted is a fairly retentive soil, yet free from stagnation.

The soil being made ready the next thing is to prepare the cuttings. These should consist of the current season's growth, well ripened, and if possible with a “heel” of the last year's wood. When we say current season's growth we mean that which was first produced this season. The second growth is quite useless, as it is not ripe. Smooth over the “heel” with a sharp knife. The cuttings may vary in length from 6 inches to 12 inches, but if possible procure them of the latter length, then one may plant them deeper, where they are more removed from outside influences. Do not remove any eyes, as frequently those at the base will throw up growths even when the tops are injured by frost.

We prefer to first prepare the soil and plant afterwards, even allowing some days to elapse between, as then the soil settles down. As the making of the cuttings proceeds they may be tied up in bundles and covered over temporarily with soil. Rather than plant the cuttings under unfavourable circumstances we should prefer to make them now; bury them entirely in some good soil in a protected part of the garden, then plant in March or April. Cuttings planted now have much to contend against, such as winter frosts, which will lift them out of the ground quite 2 inches or 3 inches. This must of necessity leave a space beneath the base of the cutting, and unless they are pushed down again most carefully

after frost has disappeared the cutting is ruined. If Bracken Fern or quantities of leaves can be obtained a thick covering of these will of course prevent this.

When planting mark out beds 3 feet wide, and plant in short rows 9 inches to 12 inches apart. The cuttings may be about 2 inches apart in the rows. Some dibble them in, but we prefer making a trench the depth of the cuttings and thus ensure the base of the latter resting on the soil. If an inch or so of good rooting material such as sand or old cocoanut fibre be placed at the bottom of this trench, this considerably assists the rooting process. When the cuttings are placed in position dig the soil up to them, tread very firmly, and then cut down another trench, and so on. It will be seen by this that the cutting is entirely buried; but this is not important unless they are fully 6 inches in the soil.

Cuttings of Tea and China Roses if made now should be inserted round the sides of 5-inch pots of sandy soil and placed in a cold frame. They will thus form a callus, and will emit roots if placed on a gentle bottom heat in spring.

As to varieties, all the smooth-wooded kinds of Hybrid Perpetual Roses root freely, and in fact almost any kind will do so *when well ripened wood is inserted*. Soft pithy wood is useless. A few varieties we have found to succeed well are Victor Verdier, Captain Christy, Pride of Waltham, Charles Lefebvre, John Hopper, Ulrich Brunner, General Jacqueminot, Baroness Rothschild, Jules Margottin, Dr. Andry, François Michelon, Mrs. John Laing, Etienne Levet, Prince C. de Rohan, Crown Prince, La France, Augustine Guinoisneau, Margaret Dickson, Clio, Paul Neyron, Helen Keller, Jeannie Dickson, Mrs. W. J. Grant, Heinrich Schultheis, &c.

The hardy ramblers, Rugosa Roses, Lord Penzance's Sweet Briars, most of the species and single Roses also root most readily. The Tea-scented, Hybrid Teas, Chinese, and Polyanthas will all grow freely from cuttings. For autumn insertion, as described, procure the cuttings if possible from pot-grown plants, otherwise only insert wood from outside or wall plants that can be obtained thoroughly ripe.

There is much to be said for own-root Roses, and several experiments we have made have resulted in plants of surprising vigour on their own roots, whereas those grafted were, in comparison, a failure. Marie van Houtte

on its own roots was as beautiful as anything we have had in a large collection of the best of the older and newer Roses this year. It is even now giving an abundance of large, finely-coloured flowers.

## KEW NOTES.

### INTERESTING PLANTS IN FLOWER.

#### Temperate House.

CINCHONA OFFICINALIS, Hedychium gardnerianum, and Lindenberga grandiflora.

#### Palm House.

Ixora coccinea varieties, Licuala grandis, Medinilla venosa, and Sterculia neocalaledonica.

#### Water Lily House.

Araujia grandiflora, Clerodendron disparifolium, Diehorisandra thrysiflora, Hedychium coronarium, and H. spicatum.

#### Orchid Houses.

Acineta Barkeri, Catasetum darwinianum, C. tabulare, Cattleya Acclandiae, C. Loddigesii var. Harrisonae, Cyaneochis purpurascens, Cypripedium Charlesworthii, C. crossianum, C. spicerianum, C. tonsum, Dendrobium Phalaenopsis var. statterianum, Epidendrum Armstrongii, E. raniiferum, Ionopsis paniculata, Miltonia candida, M. spectabilis var. moreliana, Neobenthamia gracilis, Odontoglossum andersonianum, O. aspirinum, O. grande, O. madrense, Oncidium Forbesii, O. varicosum, Polystachya luteola, P. rufinervia, Rodriguezia fragrans, and Stanhopea oculata.

#### T Range.

Echmea fulgens, E. f. var. discolor, Begonia (various species and varieties), Brunfelsia americana, Buphanes disticha, Caraguata lingulata, Clavija Ernsti, Daedalanthus parvus, Erica conspicua, E. mammosa, E. spicata, Haemanthus coccineus, Ipomoea rubro-caerulea, Mesembryanthemum blandum, Nerine atrorubens, N. curvifolia, N. Moorei, N. sarniensis and many varieties, Pentas carnea, Pingueula caudata, Pitcairnia karwinskiana, Spathiphyllum cannaeolimum, S. floribundum, S. Minahassae, Tillandsia duvaliana, and Tupistra grandis.

#### Succulent House.

Euphorbia splendens, Kalanchoe kewensis, Senecio subscandens, and Solandra grandiflora.

#### Greenhouse.

Acacia platyptera, Angelonia salicariifolia, Aster cordifolius elegans, A. ericoides, &c., Caryopteris Mastacanthus, Celosia pyramidalis, Kochia scoparia, Lantana (garden varieties), Primula obconica, Salvia splendens, Tibouchina macrantha, and other things.

#### Orchid House Wall and Border.

Amaryllis Belladonna, Punica granatum var. nana, Raphiolepis indica, Schizostylis coccinea, and Watsonia marginata.

#### Shrubs.

Colletia cruciata, Coronilla emerosides, C. Emersus, Lespedeza Sieboldii, Ligustrum lucidum, and L. Quihoui.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

October 16.—Annual Dinner of the United Horticultural Benefit and Provident Society, Holborn Restaurant.

October 20.—Meetings of National Chrysanthemum Society's Floral and Executive Committees.

October 21.—Royal Horticultural Society, meeting of committees, Drill Hall, Westminster; Horticultural Club, 6 p.m., discussion after dinner on "Fruit Trees in Pots," opened by Mr. T. Alfred Rivers.

October 28.—Croydon Chrysanthemum Show (two days).

October 29.—Kent County Chrysanthemum Show at Lewisham (two days); Highgate Chrysanthemum Show (three days).

October 30.—Penarth Chrysanthemum Show.

October 31.—Finchley and Leyton Chrysanthemum Shows (each two days).

**Anemone-flowered Dahlias.**—These represent a strain of dwarf single Dahlias, having, instead of the usual yellow button-like centre, a cushion of quilled florets, as in the case of a quilled German Aster, but not so perfect in form. They are of continental origin, and being of dwarf, bushy growth, fairly free, and throwing their flowers well above the foliage, there are possibilities of development in them, and this has been recognised by Mr. John Green, of the Norfolk Nurseries, Dereham, who has selected some twenty or so varieties for further trial; the best will be seeded from and every effort made to develop something worthy of perpetuation. The tastes of Dahlia lovers have broadened during the past twenty-five years.—R. DEAN.

**Anemone japonica.** Autumn-planted plants, especially of late, make but a spare growth the first season, and do not throw the fine blooms they otherwise would if fully established; then they grow tall and bloom abundantly and well. This should be borne in mind by amateurs who are sometimes led to think the plants were constitutionally weak when really it is not so. With me all the varieties do well on heavy and light ground alike, but light ground—and especially so where the position is open and sunny—favours early bloom. I cannot help expressing my regret that the type with its large deep rosy and somewhat double flowers is so little grown. I think that when well established and in vigorous growth it is one of the finest; but gardeners appear to prefer the rose-coloured *hybrida* and the white variety.—R. DEAN.

**Lespedeza Sieboldii.**—In places where frosts are not experienced early in autumn this plant is well worth growing, as it flowers during the end of September and October when the outdoor garden is losing its beauty. It is found both in China and Japan, and has been in cultivation for a considerable time. The root-stock is woody, and from this long shoots 3 feet to 4½ feet in length are produced, which here never survive the winter, being cut down to the ground-line by the first sharp frost. The flowers are rosy purple, and in long pendulous panicles from the upper half of each shoot. It thrives well in ordinary soil, and when planted to form a mass in front of the shrubbery is very effective, adding a touch of colour at a time when the flowering period of most shrubs is long past.—D.

**Cestrum Smithii.**—This garden form of Cestrum is quite distinct from any other member of the genus, all of which are far better known under the generic name of *Habrothamnus* than that of *Cestrum*. The best known of all is perhaps *Cestrum (Habrothamnus) elegans*, a half climber, which is particularly useful for clothing greenhouse walls, pillars, or similar places. The tubular-shaped flowers, which are borne in good-sized clusters throughout the greater part of the year, are purplish red. Besides this we have *C. llewellyi*, a garden variety in which the flowers are bright crimson; *C. aurantiacum*, with orange-coloured blossoms; and, lastly, that at the head of this note, *C. Smithii*, in which the flowers are deep

rose on the exterior, with the expanded mouth somewhat lighter in colour, and borne in the greatest profusion. It certainly affords a very pleasing variety from the others. The *Cestrums* belong to the order Solanaceæ, and the individual flowers are somewhat in shape in the way of *Fabiana imbricata*, whose resemblance to a Heath, both in foliage and flowers, has been before now noted in *THE GARDEN*, but like the *Cestrums* it is also a member of the *Solanum* family.—T.

**Blue Hydrangeas.**—I have just read the article on "Blue Hydrangeas" by Mr. Joseph Meehan, and I will give you my experience with *Hydrangea Otaksa*. The plant produced pink blooms, as it should, until it was three years old; then I put it in a large tub, placing quite a lot of coals—ordinary coals sifted from the stove ashes—in the bottom of the tub, when I repotted the plant in the autumn. When it flowered the past spring the blooms were blue instead of pink. I thought the plant took its colouring from the material I used for drainage. At any rate, the result created a demand for blue Hydrangeas. I intend to try the experiment again this winter.—MRS. CHARLES GREEN, in the *Florist's Exchange*.

**Andromeda mariana.**—The various evergreen Andromedas are much planted, partly because they are evergreen as well as for their racemes of white flowers. But with all their good qualities they are not more beautiful than the native deciduous one, *A. mariana*. Of beautiful growth and foliage, it bears in spring lovely white blossoms, looking like those of the Lily of the Valley, which the leaves set off beautifully. A peculiar characteristic of this Andromeda is that it nearly always flowers again in late autumn.—T. W.

**Flora of the Wordsworth Country.**—Mr. T. R. Hayes, alpine plant specialist of Keswick, some time ago read a most interesting paper before the Keswick and District Horticultural Association, entitled "The Flora of the Wordsworth Country." The lecture was made additionally interesting by a very large collection of Ferns, plants, and flowers. Speaking of the old home of Wordsworth, Mr. Hayes said there the Snowdrops, Foxgloves, Primroses, Celandines, and Daisies emerge from the grassy slopes in profusion. Surrounding the memorable well are Moneyworts, Polypods, Blechnum, Parsley, Shield, and Lady Ferns revelling in the ever-ceaseless spring. There are herbs and other beautiful lakeland flowers here—White Heathers, Roses, Jasmines, Rosemary, Violets, Gowans, and Columbines.

**Cotton seed.**—A remarkable feature of the trade of the past year has been the development of traffic in cotton seed, of which 150,000 tons have been shipped from Bombay in the fifteen months ending last June, compared with only 1,800 tons in 1898-99. The whole has been sent to the United Kingdom, where a brisk demand has sprung up for this previously almost worthless bye-product of the Cotton industry for such productions as the manufacture of oil and margarine. We regard this as very satisfactory. So far back as 1897 we strongly advocated a careful consideration of Cotton seed for the valuable oil it yields, as well as for its oil-cake as a cattle food and manure.—*Indian Gardening and Planting*.

**A novel idea.**—The director of the Peradeniya Botanic Gardens, Ceylon, has put into practice a plan which appears to the *Horticolle* to be an excellent one. At the entrance to the gardens has been placed a notice board upon which are notified each day the most rare and interesting plants in flower. Habitual visitors thus know where to go, and avoid much loss of time. Might this plan not be adopted in other similar establishments?—B.

**Three good new dwarf bedding Lobelias.**—The remarks of your correspondent Mr. Gumbleton, under the above heading on page 210 of *THE GARDEN* of the 27th ult., raise the question as to what is considered an ideal Lobelia. The two varieties Newport's Model and Chapman's King Edward both possess a distinctly large eye. On the other hand, in the flower of Mrs. Clibran the eye is very small. The size of the eye naturally

affects considerably the appearance of the plant as a whole. The smaller it is the more telling the blue will be, and vice versa. Many prefer a flower with a small eye for this reason, but after all it is perhaps matter that is best left to individual taste. I can quite bear out what your correspondent says as to Mrs. Clibran being the most profuse bloomer. Grown side by side with Newport's Model, as the writer saw them during this last summer, the difference in freedom of bloom was most remarkable. I understand Messrs. Clibran have been well satisfied with the reception this variety has met with since its introduction.—G. C.

**Toogood's culture of vegetables.** There is much valuable information contained in the 150 pages or so of this booklet, published by Messrs. Toogood and Son, Southampton, at the modest price of 3d. There are many useful illustrations dispersed throughout the book, which add materially to its value. A feature of Messrs. Toogood's book lies in the monthly calendars, where instructions are given as to seasonable sowings and plantings.

**Notes from Ireland.**—The absence of sunshine which has characterised the present month has seriously interfered with the usual brilliancy of our autumn tints, and has given our choicest bits of sylvan landscape a wintry and bedraggled look entirely different from the enchanting variety of golden and bronze shades usually seen in our Irish woodlands at this season. Autumn flowers—and summer flowers, too, for no one would think of denuding his beds or borders this year while a vestige of bloom remains—are with us in plenty, and seem to compensate in some measure for the lack of beauty in the deciduous foliage. At Glasnevin Gardens the display of border flowers just now is exceptionally fine. Mr. Moore's collection of Asters—comprising every known kind of sterling merit, as well as many new forms raised by himself and other eminent hybridists—are deservedly worthy of mention, and constitute in themselves a picture worth going a long journey to see. The same remarks apply to the Glasnevin collection of Tritomas, which certainly comprise a far greater number of distinct forms of this showy autumn flower than is generally supposed to be in existence. Beautiful as the Tritoma is as a bold border flower, it is perhaps in no place more effective than when seen in large clumps by the margins of lakes or through vistas in the landscape, particularly when its bright flaming spikes are seen standing out in relief against a dark background. I was particularly struck with the brilliancy of this subject recently in the charming grounds of Lord Duncaon at Bessborough, in County Kilkenny, where Mr. J. G. Weston uses it with marvellous effect in the brightening of the landscape. The Colchicums at Glasnevin are very lovely just now, and every form worth having is there. A considerable addition has been made to the rock garden within the past few months, in the recesses of which are already established hundreds of rare and beautiful alpines, which will no doubt be duly mentioned in future notes. The hardy fernery, too, has undergone considerable enlargement, and, as many horticulturists know, now contains one of the best collections in the kingdom. In one of the greenhouses I was pleased with the bright blue of a large group of *Browallia speciosa major*. It seems curious that this free-flowering plant is not more extensively grown, as I do not know of a more lovely blue at this season for greenhouse decoration, particularly when we remember that this colour is rather scarce just at this season. As usual, a brilliant display of bloom is to be seen in the greenhouses, Begonias, scarlet Salvias, and zonals constituting the principal features. The show of Orchids is rather small, but very effective. I was much struck with the beautiful white flowers of *Habenaria Susanne*, some of the spikes of which were fully 3 feet high. Some lovely plants of *Vanda cærulea* were in evidence, as also were several charming specimens of *Miltonia moreliana*, *Oncidium dasystyle*, *Odontoglossum grande*, *Cattleya gaskelliana*, *Cattleya schofieldiana*, and various *Culogyne* and *Cypripedium*.—T. SHAW.

**Romneya Coulteri in Sydney.**—“J. A.’s” note in THE GARDEN of August 16, page 120, reminds me of a wonderful plant I saw of this in Mr. Pitt’s (of Sydney) garden in the Blue Mountains. It not only formed a large bush, but spread over the ground by its underground shoots, so that it had to be kept in check by a free use of the spade in all directions. I asked Mr. Pitt if he could account for this rampant growth, and he suggested that its roots may have got into a cesspool which existed on the spot where it was growing, thus showing the plant is a gross feeder, and this may be a reason why one so generally sees this plant looking like an unfortunate person whose life is maintained on one meal a week.—PETER BARR, V.M.H., Cape Town, S.A.

**Saxifraga sarmentosa tricolor superba.**—A large bed of this striking and richly variegated plant is one of the features at the Norfolk Nurseries of Messrs. Hobbies and Co. (John Green) at Dereham. During summer the plants are put out on a raised bed, formed along the middle of one of the span-rooted plant houses in the nursery, and some distance from the glass. Here it grows freely and colours grandly, and even now throws out its Strawberry-like runners, and as soon as they have rooted into the soil they are taken off, potted into small pots, which are placed upon a shelf near the glass, where they are wintered, and here they grow into charming tufts for sale in the spring. It is a plant a little difficult to manage, but it is such a delightful subject that it is worth making the effort to keep it in good character. It is a plant for culture under glass, and they who succeed with it may reasonably take some credit to themselves for their success. Things easily grown are plentiful enough, but there should be enterprise enough in the breasts of some lovers of plants to induce them to make an attempt with subjects which require care, skill, and patience to secure proper development.—R. D.

**Phlox (decussata) Sylphide.**—In some catalogues this fine Phlox is known as La Sylphide. It is in very fine character in the gardens of the Royal Horticultural Society at the present time, and it well deserves the award of merit given to it by the floral committee. It is described as “a lovely pure white, of nice dwarf habit, flowers very large, excellent, free-flowering,” and this hits off the variety accurately. It is of such free growth that it sends up numerous shoots from the base, and these bloom successively. It is one of the best white perennial Phloxes in cultivation. Some would go the length of stating that it is the best, and they would not be far wrong.—R. D.

## CHRYSANTHEMUMS.

### EARLY-FLOWERING CHRYSANTHEMUMS AT TAMWORTH.

A MOST interesting and thoroughly practical trial of early-flowering Chrysanthemums is carried out by Mr. William Sydenham, in his gardens at Bolehall House, Tamworth, Staffordshire. Considerably over 3,000 plants in about 250 varieties have been acquired, and with these a trial of a very comprehensive character has been carried on for some time. Many sorts which were discarded by most growers years ago have in this trial come to light again, and when making comparisons it is easy to see that a certain proportion still deserve more extended culture. This is more noticeable in the case of the Pompon kinds, where such sorts as Anastasia, a pleasing rosy purple flower, is developed in profusion on a very dwarf and branching habit of growth. Little Bob, which some trade growers wrongly name Scarlet Gem, is still a valuable border plant on account of its dwarf and bushy growth and its rich deep chestnut-crimson colour, which becomes pale with age. The blooms are quite miniature. Blanche Colombe, white and free flowering; Flora, rich bright yellow; White St. Crouts,

St. Crouts, light pink; Mme. Picoul, rosy purple; Frederick Pelé, deep crimson-red, tipped gold; and many others, still prove their value for outdoor displays.

Mr. Sydenham’s idea in carrying out this extensive trial of early-flowering varieties was to test the large number of so-called early-flowering kinds. Therefore, on Saturday, the 27th ult., an invitation was given to those interested in popularising the early Chrysanthemums to be present, first, at a display of cut flowers, sent by growers from different parts of the country in competition for four silver cups; and, secondly, for the purpose of inspecting the trial of which so much has of late been heard. The importance of the event cannot be too highly estimated, as its result will be for the benefit of gardeners and gardening generally. The National Chrysanthemum Society was represented by Mr. Thomas Bevan and Mr. J. H. Whitty, chairman and vice-chairman respectively, and other members of that body. Subsequent to the luncheon—at which speeches eulogising the excellent qualities of the early-flowering Chrysanthemums were made, and on which occasion thanks were expressed to the host for his invaluable work in this direction—the guests proceeded to view the display. This trial largely exceeded the trial of early-flowering Chrysanthemums carried out by the Royal Horticultural Society at Chiswick in 1897. The plants were arranged in double rows of considerable length and in alphabetical order. By this means, with a printed list in one’s hand, it was an easy matter to make a careful inspection of the different sorts. The plants when placed in their permanent quarters in early May were planted about 3 feet apart, and the same distance allowed between the double rows of plants. The moist weather of the late summer is responsible for the taller growths of many of the plants, and on this account some were disposed not to give a proper share of attention to the taller sorts. That the Japanese varieties are the more popular nobody could deny, and evidence was not wanting of the partiality meted out to them. All the members of the Mme. Marie Masse family of Chrysanthemums were there. In addition to the pink-mauve blossoms of the parent variety, there were those of Ralph Curtis, creamy-white; Robbie Burns, salmon-cerise; Crimson Marie Masse, chestnut-crimson; and Horace Martin, the best of rich yellows in the early-flowering section. This is an ideal type of border Chrysanthemum, as the plant is bushy and branching, is not more than 2½ feet to 3 feet in height, and flowers profusely. The plants come into flower early in August, and continue blossoming until the very severe frosts bring their display to an end. An invaluable characteristic of the newer kinds is the manner in which the flowers are carried well above the dense mass of foliage. The trial, which may be regarded as a kind of informal conference, demonstrated very clearly and distinctly the superiority of the plants just alluded to over those in which the dense growths at their apex prevented the individual blooms from displaying themselves. Those with long foot-stalks made a bright picture in the landscape, whereas those without this advantage were much less effective in their display.

The less robust sorts were quickly noticed, and they are sure to decline in popular favour. There were instances in which a kind of fungoid disease—not the much-dreaded leaf-rust—appears to be inherent, and in consequence of this undesirable attribute, however pretty may be the flowers, the plants are sure to be discarded in favour of others with better constitutions, even if the blooms are not quite so refined and pleasing. The trial also proves how mixed is the stock of certain specialists. Acquiring the stocks from so many different sources has proved most conclusively the carelessness of some distributors. In some cases the names are generally recognised as synonymous, but there is no reason why Yellow L’Ami Conderchet should also be sent out under the names of Golden Drop, Golden Shower, and Golden Fleece. The trial will have the effect of placing this sport from L’Ami Conderchet under its proper descriptive name of Yellow L’Ami Conderchet. It is curious to

note how a plant may be lost to the public for a few years and subsequently come into notice under quite a different name. A pretty French novelty of the year 1895 was distributed last season under quite another, and, in this instance, an English name. Such an occurrence no doubt is accidental, but on the face of it the result represents a curious coincidence. Everyone present at the trial expressed themselves highly delighted with all they saw, and there is every reason to believe that an impetus will be given to the cultivation of the early-flowering Chrysanthemum for the hardy flower border as a result of Mr. William Sydenham’s efforts. A small committee of leading experts went carefully through the whole collection, proving the correctness of the different stocks, and also paying special attention to those which may be regarded as synonymous sorts. Glorious-weather favoured the function, so that everything was carried out under pleasant conditions. The event may be regarded in the light of a red-letter day in the history of the early-flowering Chrysanthemums, and all who participated in the event were well pleased.

D. B. CRANE.

## NEGLECTED GARDENS. IV.

### THE ROCK GARDEN.

TO-DAY the neglected rock garden must receive our attention. Here the neglect of years will be more apparent than elsewhere probably, for of all objects an overgrown and neglected rock garden is the most pitiable. It is not that rock gardens require more attention than other portions of the garden; rather, I should say, less, and a little work in them goes a long way, but that little is very necessary.

Let me describe the appearance of a really neglected rock garden. The rockwork itself has sunk or become disreputable and in ruins, the soil has become exhausted, and all the choicer plants choked and destroyed by a few vigorous and rampant-growing subjects such as Arabis, Alyssum, and some of the commoner Saxifrages. Seen in the spring time this old rockwork would be a beautiful garden picture, for the Arabis and the Alyssum and Saxifrages flower about the same time, and a grand display they would make being in such great quantity. But that would be the beginning and the end. From the time that these plants ceased to flower the rockwork would be without any display of colour for the rest of the year. Now a well-planted rock garden should have flowering plants for at least nine months out of the twelve.

How shall we deal with this neglected rock work? If not a natural feature in the garden—and few rock gardens, alas! are that—the most effective method is to remake it entirely, carting away the old soil and replacing it by fresh. Should there be by chance a few of the choicer plants left, they must be taken up with great care, as in many cases the roots of these tiny subjects run deep, far more so than the height of the plant above ground would lead the inexperienced to imagine possible. Of course, such a drastic measure as remaking the rock garden may be unnecessary. Much will depend on the number of years that it has been allowed to run wild, but in any case it will be found advisable to renew the soil as much as possible without loosening the rockwork.

It should be remembered, either with regard to the old rockwork or in rebuilding it—if that is undertaken—that overhanging portions, picturesque as they are, should never be allowed. Plants cannot thrive under such projections, and to form a structure or put plants where a kindly Nature cannot nurture them is bad. As far as possible every portion of the rock garden should be able to benefit by dew and rainfall, the lower portions as much as the upper. Neither should the rockwork be so placed that the rain and soil are washed from it. Plants cannot flourish—barely can they live—under such conditions, and certainly cannot display their true beauty.

As to the form it shall take, due regard must be paid to the lie of the land of the garden generally, and also of the surrounding country. If

these are flat a cliff-like rock garden is scarcely so suitable as one of a flatter and wider spreading nature. If steps can be introduced either in or leading to the rock garden they add much to the artistic possibilities. In replanting, the choice positions will not be accorded to those familiar things already mentioned that so lately overran the whole. These things are too beautiful and too useful not to find a welcome place in the rock garden, but they must be kept within reasonable limits. They should be placed at the outskirts, where a large clump of them will be effective and charming, and where they can be allowed a wider range than in the choicer positions.

There are so many delightful things that we would seek to find places for, many of them of as easy culture as the familiar subjects already named. The veriest novice need not fear to introduce them. And here I would say: Let him ever be on the look out to discover any dwarf plants that yield those large and important-looking blossoms that go so far to furnish and give character to the rock garden. Such plants are too often omitted, generally, I believe, through want of being known. To a few of these I would call attention as being especially valuable from a decorative point of view. For spring-flowering there is *Aster alpinum*, a charming plant with pale mauve composite flowers, and lasting in blossom for a considerable time. For summer blooming there are those large-flowered dwarf *Campanulas*, *C. carpatica* and *C. turbinata*, both white and blue in each variety. And to go on until the frost comes are the beautiful trailing (*Enothera*), which are well-nigh indispensable.

Other plants that can ill be spared from the rock garden, however small, are: *Aubrieta*, one of the most charming and hardy of spring-flowering rock plants, and to be grown either in the mauve or rose-coloured varieties (the two colours do not accord well at close quarters); *Lithospermum prostratum*, with its rich blue blossoms, which for charm of colour it is difficult to overrate. Nearly all varieties of the dwarf Phloxes are charming for restocking our rock garden. The best of all is known as *Vivid*, and is a variety of *setacea*. So good are these cheery-flowered plants that the only thing to regret is the fact that their flowering period does not last longer.

But it is easy enough to find many spring-flowering subjects to make beautiful the rock garden during that season. The difficulty is to maintain a display through the summer months. It is here where so many rock gardens spell failure; but, difficult though it may be to keep up a brilliant mass of colour during the hottest time of the year, it is by no means impossible. We may rely on *Lychnis haageana*, *Geranium argenteum* and *G. cinereum*, *Cerastium tomentosum*, *Silene Schafta*, and the white form of the pretty Fern-leaved *Corydalis*; *Dianthus neglectus*, one of the gayest little flowers that grow; *Dicentra formosa*, that begins to flower in spring and continues in bloom for months if the weather is not too dry; and, humble though it be, *Lysimachia Nummularia*, or, to give it the name known to thousands, Creeping Jenny, together with the golden-leaved variety; and, of course, there are many besides these.

There is another type of plant that always seems to me to be particularly happily placed when growing out of rockwork, especially when growing out of some steep bank or wall—I mean those plants that bear their flowers on very slender stems growing out of a thick tuft of foliage at the base—plants like the Columbine, *Polemonium*, and some of the *Spiraeas*.

If, during the first summer following the making or restocking of the rock garden, there exist bare spaces, it must be remembered that there is a wealth of hardy annuals of a dwarf character to fill the gaps. The annual *Campanulas* are quite in keeping with other subjects of the rock garden, so also are the annual (*Enotheras*, and really beautiful beside and among a host of others I would name *Kaufussia*, *Leptosiphon roseus*, *Iberis odorata*, *Phacelia campanularia*, and *P. tanacetifolia*.

F. M. WELLS.

(To be continued.)

## THE FLOWER GARDEN.

### DWARF BULBOUS IRISES.

**T**HREE are two periods when attention may be advantageously directed to any good group of hardy plants. These are—firstly, the natural flowering season; and, secondly, that time during which the particular group may be planted. Not a few of these dainty gems are especially suitable to the amateur gardener—the lady amateur even in greater degree perhaps—and particularly all those who delight in growing a few plants without much trouble. In the following notes the predominant colour only is given. To learn something of the beauty of these flowers one has only to be reminded of the groups exhibited each year before the Royal Horticultural Society by Messrs. Wallace of Colchester, Mr. Amos Perry, and Messrs. Barr and Sons.

These Irises may be grown in many ways. They are easily managed and grown in quantity for successional flowering, while not least in the list of recommendations is that the best and most showy are to be obtained at quite a cheap rate. Let us take some of the ways in which these things may be grown. Firstly perhaps, and most naturally to the gardener's mind, is that of growing them in pots and pans, and, indeed, in these not only may the plants be well grown but readily transferred to this or that apartment when in full beauty. When thus grown use moderate-sized pots, say those of 5 inches across, for these will take about six bulbs of flowering size. The shallow pan is singularly adapted for these Irises, and a good size is 4½ inches deep and 5½ inches wide at the top. In dealing with pots and pans it is frequently urged in catalogues that these dwarf Irises are "adapted to early forcing." If by early forcing is meant the growing of these things in much heat I can only say that nothing more quickly spoils them. In a cold house or even an ordinary frame these Irises may be grown perfectly, and, indeed, where even these do not exist there is still ample scope for their full enjoyment.

Perhaps one of the most delightful of all ways of growing these plants is in the window boxes so frequently attached to town and villa residences. Many of these window boxes are glass covered, and, fitted into the window, the latter may be

opened and the beauty or fragrance of the occupants enjoyed at will. Take, for example, the *Netted Iris* (*I. reticulata*), of the deepest and richest violet-purple, with the fragrance of the Violet, and keeping in good condition for a fortnight or even longer. This is quite a gem among the early Irises that come into flower in February. With the frame protection it is quite easy to have it in bloom in mid-February and for a month after, and certainly there is no more beautiful flower than this. To ensure a good succession in the best condition adopt the sectional window box, having three inner compartments for the convenience of changing, and one or two duplicate sets also. Another charming kind that has gained much favour in the last year or two is

*I. Heldreichii*, a lovely sky blue flower, with rich deep blue falls on which are a few spots. Not only is this quite a gem among the newer additions, but it is vigorous, early flowering, and very hardy, while it will bear transplanting with impunity, even as the buds are opening. In this way it is a great gain. Yet another way of growing many of these pretty Irises is by planting a few roots in shallow earthen, or, better still, in

### ORNAMENTAL BOWLS.

These can now be obtained in several sizes, and suit the plants mentioned. Soil is not necessary, but a light, clean mixture in which to grow the plants is now sold by nurseries and others. Grown in these bowls the flowering examples are readily transferred to any apartment, and, indeed, make pretty objects arranged on the dinner-table. Out of doors the plants are grown certainly by a few in beds, in pots, or occasionally on the rock garden. But we wonder how many of those who dwell in or near London have thought of filling their window boxes with them in place of the shrub mixture of *Euonymus*, *Veronica*, *Retinopora*, and the like. Given a set of these Irises, together with *Polyanthus*, *Chionodoxa Luciliae*, or the larger *Snowdrops*, and carpeting the surface with any of the free-growing mossy *Saxifragas*, and the owner of it possesses at once a garden of rare beauty and fragrance.

*I. bakeriana*.—One of the most exquisite of the early kinds, and in form not unlike *I. reticulata*. Upper petals sky blue, lower petals white, freely blotched with dark violet. It is sweet-scented, grows about 6 inches high, and flowers naturally in the early part of February.

*I. Danfordiae*.—This little gem rarely exceeds

THE MIXED BORDER NEAR THE RIVER (HAMPTON COURT).

3 inches high, and is golden yellow with few brown spots. Flowering late in February and after. This is one of the prettiest of the entire group as it is so distinct in colour. A bowl or panful of this always gives pleasure.

*I. Heldreichii*.—This, described above, must be mentioned here also.

*I. Histroides*.—A charming delicate porcelain blue flower, very beautiful and tender in colour. Late February and early March; 5 inches high.

*I. persica*.—White and palest blue, the petals blotched with gold and purple, fragrant, and 4 inches high. A form of this called "Mardin" has flowers of satiny or silver-grey tone.

*I. reticulata*.—There are several forms of this Iris, varying chiefly in the size of the flowers, but all are worthy of cultivation. Colour rich deep violet-blue with golden blotches. Violet scented, flowering in the third week of February, and 9 inches high. The variety known as Major has the larger flowers.

*I. r. Krelagei* is a dwarf form with reddish purple flowers. It is 6 inches high, and quite early flowering.

*I. Tauri* is a new addition to bulbous Irises, and forms a fitting companion to *I. Heldreichii*, which it most closely resembles in size, &c. The colour is of a more uniform tone, bright violet-purple, the nearly black falls having a few spots of white. February and March, height nearly 6 inches.

These are among the showiest and most distinct, and are preferred in the present instance because of their stature and the almost uniform season of their flowering.

E. J.

#### A MIXED BORDER AT HAMPTON COURT.

The majority of flower borders show one of three errors: Those planted by jobbing gardeners are of a stereotyped pattern; those planted by amateurs with more zeal than knowledge are wildly experimental and the flowers kill one another's beauty by injudicious proximity; those planted by wise men without taste have the plants treated as so many botanical specimens, and the labels look like miniature tombstones. But there is another kind of border that strikes the beholder with a sensation of surprised delight; such is the border at Hampton Court. No one but an artist could have thought out such a happy combination of colour: no one but a true gardener could have put each plant exactly in the right place to appear most attractive. The colours blend so harmoniously that at a distance the border seems as much a part of the old red building as the lichen on the branches does to a tree. There are no violent contrasts, although the colours range from deepest mulberry through bright crimson and scarlet to rose-pink, from deep orange to fawn and creamy white, from purple to palest blue. It may truly be called a mixed border, for hardy, greenhouse, and stove annuals and perennials grow side by side. The border is roughly divided into three by two paths, but looking sideways it seems all one, and as though its entire length were edged with a drooping greyish blue grass. In reality tufts of grass and Violas are planted alternately. In the first division the Violas have a red tinge, in the second they are pale yellow, and in the third mauve. Behind the grass and Violas comes a bank of flowers, the plants massed together, some recurring again and again, some only appearing once, the varieties of Coreopsis and Montbretias being an especial feature.

It is needless to enumerate every plant, but the following are of interest: Aster (*Callistephus*) *sinensis*, with large single mauve, pink, and white flowers; a brilliant pink Geranium named William Brown; the old-fashioned stove plant *Asclepias curassavica*, with orange flowers; the pink Verbena Ellen Willmott, *Hydrangea paniculata grandiflora*, in pots about a dozen together, with

BORDER FRONTING THE OLD TENNIS COURT (HAMPTON COURT).

large heads of creamy white blossom. *Impatiens Sultani* is beautiful, its bright cerise flowers softened by the variegated green and white foliage of dwarf Abutilons; scarlet Lilies (*Vallota purpurea*) grow next to *Francoa ramosa*, and above the *Francoas* bend graceful sprays of *Gaura Lindheimeri*. Two plants not often seen are here—*Mina lobata*, completely hiding its support with its *Convolvulus*-shaped leaves and drooping lemon and crimson flowers, and *Nierembergia gracilis*, with pretty white and purple veined flowers. Is anything now remembered of the Mexican minister and Spanish Jesuit they are respectively named after?

Behind this flowery bank the plants grow further apart in large groups of different combinations. There are Hollyhocks, Dahlias (the most noticeable being Maid of Kent, a scarlet and white flower), Cannas, *Plumbago capensis*, Sunflowers, *Eucalyptus globulus*, white and crimson *Cosmos*, *Iresine Lindeni* (grown on to be nearly as tall as the Hollyhocks), pink and white *Swansonia gallegifolia*, Tree Abutilons, Tree Heliotropes, large bushes of *Lantana hybrida* (most of these have parti-coloured crimson and yellow flowers, but one named *Delicatissima* has violet blossoms), and Fuchsias. Many of the latter have golden foliage, one with small silver green and pink veined leaves is called *Sunray*, one with long salmon-coloured blossoms is named *Mrs. Randle*, but the most curious is the new Fuchsia with the polyglot name *Erecta von Novelty*, its short pale pink flowers point upwards instead of drooping. There is *Phlox diffusa* in many shades, some a coral red like Etna.

Here and there is a climbing Rose, a scarlet *Tropaeolum*, or patches of Ivy-leaved Toad-flax on the side of the wall; where it is left bare it makes a beautiful background. The top of the wall is covered with hanging creepers, such as *Wistaria*, and white, purple, mauve, and claret-coloured Clematis. This border is so well kept that on the day this was written (August 28) there was not a dead flower to be seen. There are other interesting flower-beds and borders in the grounds, but the one described is the most picturesque.

WINIFRED SPURLING.

A PLEA FOR THE ENGLISH PANSY.  
THE moist, cool summer has been favourable to the development of both the English show and the fine fancy Pansies. But few comparatively in

the South now cultivate the English Pansies—the yellow grounds, white grounds, and selfs. There is a certain refinement about them of a very attractive character. There is a winsomeness about the refined white and yellow grounds which appeals to all who value the florist's quality in flowers, and having this season grown beds of the old-fashioned show as well as of the finest of the fancy varieties, I have come to the conclusion that there is much more of scope in the variations seen in the show than in the fancy type. Both the types have made a good growth and bloomed freely. There is a persistency in many of them that I miss in some of the newer Violas, which seem to go down rapidly after blooming freely for a few weeks.

The points of quality in the show Pansy may be reiterated with advantage. The outline of the corolla is nearly circular, in a perfect flower there is no serrature on the petal edges, the petals lying close and evenly one upon the other. They should be stout in substance, and of a rich glossy velvety appearance, two points gained after many years careful selection; the ground colour—whether yellow, cream, or white—clear and pure, and nearly or quite circular, so as to admit of an equal width of marginal colour or belting on the three lower petals of the flower. A Pansy, whether show or fancy, has five petals, and in the case of a yellow, cream, or white ground the two upper petals add their breadth of marginal colour to that of two of the lower ones, and thus there is a greater width of marginal colour at the top than at the sides of the flower. The belting or margin is a matter of considerable moment, that round the lower petals should be of exactly the same shade as that on the upper ones, and it should not strike into the ground colour, but be as even as possible along the inner edge. Lastly comes the blotch, a matter of great importance also. The attainment of this property occupied the fathers of floriculture many years; they had to transform the lines round the eye of the Pansy into a blotch. Latter-day florists have toiled to make the blotch dense and compact, seeking to get rid of any tendency on its part to shoot out its fine points of colour into the ground and so form a "starry" blotch. The eye of the flower should be gold or orange, solid, compact, and not running out into the blotch.

Self flowers of whatever colour should be of the same shade throughout, whether white, cream, yellow, crimson, maroon, blue, or any other shade,

and the denser and more well defined the blotch the better. How very difficult it is to get a perfect flower among seedlings is well known to those who raise them, and it is this fact which accounts for the slow increase of the named show varieties. I am bound to say that of the named varieties I cultivate they are, on the whole, of compact growth, free blooming, and continuous, and last autumn, after the fancy Pansies and Violas had ceased blooming, the show Pansies carried on the floral succession to a much later period. A selection of the best English show Pansies will be found as follows:—

**Yellow grounds.**—James Craik, John Kirkwood, Robert Strang, Busby Beauty, Dr. J. K. Campbell, P. C. D. Boswell, and R. M. Wenley.

**White grounds.**—Agnes Kay, J. McLellan, Jessie Thomson, Mrs. Brown, Mrs. M. Stewart, and Mary Stewart.

**Dark selfs.**—Leslie Melville, A. Lewis, Dr. Inch, and William Fulton.

**White selfs.**—Annie Muir, Bobby Harper, Busby White, and Mrs. Gladstone.

**Primrose and cream selfs.**—Annie D. Lister, Mrs. W. D. Crosbie, Allan Primrose, John Kidd, and May Stewart.

**Yellow selfs.**—John Henderson (extra fine), James Bell, Busby Yellow, Maggie Milne, and Mrs. John Hunter.

The show Pansy, in regard to raising new varieties and cultivating them, is essentially a northern flower, and it is always well when a collection is secured for the south to have the plants from a northern locality. If planted in the autumn the bed should be a rich loam, with some grit mixed with it, and the bed should be raised 4 inches above the ground level to allow of drainage when drenching autumn and winter rains fall. A few sprays of Fir placed on the windward side of the bed will be found a great protection from wintry and March winds. The finest blooms are obtained from well-established plants put out in autumn. If it is advisable to hold over the plants and plant out in spring it is well to pot and winter them in a cold frame, planting them out in March, and disturbing the roots as little as possible. The cultivation of Pansies in pots to secure fine exhibition blooms, and also for show as pot plants, was much followed fifty years ago, but is now practically a lost art, and yet it is a process which tests the skill of the cultivator to the utmost.

Propagation is done by means of cuttings taken in May and June from the young growths produced from the centres of the plants, and if they can be inserted in a bed of sandy soil in a cool shady spot, and a handlight be placed over them, they soon make root, or they can be pricked off in such a bed made up in a cold frame, or in pans of suitable compost, and kept shaded from the sun. Another plan is to top-dress the plants with fine soil two or three times during the summer, which assists them greatly and encourages the production of young growths, and in September lift and divide them, planting the strongest out in well-prepared beds and the weakly ones in a nursery bed to grow on. A free-growing variety will produce a good quantity of stock.

Red spider and aphides are troublesome at times, and especially in periods of drought and drying winds. The plants should be kept growing as vigorously as possible, and a favourite insecticide with some of the Scotch florists is Taddy's snuff, which they sprinkle on the affected shoots. Mildew is often very destructive to the Pansy tribe, and sulphur, in the form of a fine powder thoroughly dissolved in water and applied by means of a syringe, is found a good remedy, though some apply the powder in a dry state.

R. DEAN.

a lot of money out of it." Then he went on to say: "I am by some blamed for giving a new name to an old Rose," and asked my opinion. I said that under the circumstances he was quite justified. I did the same myself when working on Peonies. If I found a real good thing without a name I gave it a provisional name, which in time often became the permanent one, as it was no uncommon thing to have the same variety under half a dozen names. Then he told me the history of the Rose. Not having my American notes, your readers must be satisfied with the facts. An old gentleman—a great rosarian who continually imported all the new European Roses—died, and his family said to my informant: "Take any of these Roses you please, and, as there were no names, I selected this particular one and discovered its great value as an indoor Rose. I exhibited it under the name American Beauty, and the trade bought it freely at a good price. I had a large stock and did well out of it." Someone sent a plant to France, and the correct name was attached, but its trade name was too well established, and the demand for the flowers under its adopted name was universal. Single specimens with a stem 5 feet to 6 feet often commanded 2dols. to 3dols. On the man's part there was no desire to claim America as the birthplace of the Rose; therefore any Americans who say the Rose was raised in the United States are ignorant of its history. It was christened in the United States. Its correct name at the time its adopted name was given—American Beauty—was unknown.

Cape Town. PETER BARR, V.M.H.

## NOTES ON HARDY PLANTS

### ASPERULA LONGIFLORA.

**A**SPERULA LONGIFLORA, though not new, seeing that it was introduced from Hungary in 1821, seems to have fallen into neglect, but it is one of the few Asperulas which are most valuable for cutting. I think it is even better than *A. hexaphylla* for this purpose, and it well supplies the place of *Gypsophila paniculata*, which it anticipates in its season of flowering. Recently I have observed it more often at flower shows, and a good bunch is attractive when thus shown. As I know *Asperula longiflora* it is pure white, but the description given in a good current work of reference gives the flowers as "whitish, yellowish inside, and reddish outside," but I believe this is erroneous, unless the one in cultivation is a purer variety than the original. It also grows taller than the height of 6 inches given in the books. The flowers are long, quite pure, their graceful habit making them suitable for many purposes in arranging cut flowers. I saw a good breadth of it in an Edinburgh nursery the other day, and I was informed that it had brought in a large sum of money from the cut flowers alone. *Asperula longiflora* is a hardy perennial, and is easily increased by seeds or division. It flowers for a considerable time in summer, and in this abnormal year lasted well into September.

### GYPSOPHILA PROSTRATA.

THE dwarf *Gypsophilas* are beautiful plants for the rock garden or for the front row or edging of the herbaceous border, though the trailing habit of *G. prostrata* and *G. repens* makes them really more suitable for the first of these places. One of the best of these dwarf *Gypsophilas* is *G. prostrata*, which when in flower looks very pleasing with its green leaves and reddish or pinkish-white flowers. It is unfortunate there is in some nurseries and elsewhere confusion between *G. prostrata* and *G. repens*, so that anyone ordering one may receive the other. This is partly due to the fact that *G. prostrata* of Allioni is synonymous with *G. repens* of Linnaeus, while the true *prostrata* of Linnaeus is distinct, and is the one to which I am now referring. It likes a light soil with a little chalk or lime in it. It comes well from seeds, but

I have not been very successful with cuttings of this pretty rock plant. Its best place is really on the rockery in full sun, and in such a position that it can hang from the top of a large stone, which it will cover in summer with foliage and flowers.

### STATICE DODARTII.

THIS Statice is referred to as *S. auriculæfolia*, but the one I have seen in several gardens under the name of *Dodartii* is taller, also differs a little in the breadth and length of the foliage. It may only be a variety of *S. auriculæfolia*, but if so it is distinct enough when seen beside it to warrant its retention. These Sea Lavenders are pretty plants, and with the exception of a few species, such as *S. latifolia*, are very scarce in private gardens. Several of the species are not good perennials, and are not hardy enough for our winters, but there are still a good many, such as the one under notice, which are well worth growing. *S. Dodartii* grows fully a foot high, and has pretty lavender-blue flowers. These may be dried for winter decoration, but they also look well in the border in autumn. These Sea Lavenders are usually propagated by seeds, but it does not seem generally known that the greater number will increase readily by means of root-cuttings.

### ASTER EDNA MERCI.

THIS Starwort, sent out by Mr. Amos Perry, of Winchmore Hill last spring, promises to be useful on account of its colour and moderate stature. We have for some time been in want of some varieties of the *Novi-Belgii* type, but with pink or red flowers. The *Novæ-Angliæ* varieties are a shade too tall for some positions, and in exposed places are difficult to keep up during autumn gales. In Edna Mercia we have a variety of *Novi-Belgii* approaching the colour we desire. It is not red, but may be called a warm pink or rose. This year the flowers are small, but I anticipate that they will become larger when the plants are better established. The height this season in light soil is just 3 feet, but it will likely grow a few inches more another year. A. Edna Mercia has been in a reserve border for trial, but I am so much pleased with it that it will be transferred to a more conspicuous position.

### LIATRIS GRAMINIFOLIA VAR. DUBIA.

I AM pleased to see that this fine *Liatris* has been given an award of merit by the Royal Horticultural Society's floral committee. It deserves all you say of it in your report in the issue of the 27th ult. It is quite hardy, and has increased at the root considerably since I got it from Baden-Baden about two years ago. The use of the *Liatrises* in the garden is much to be commended, especially such as bloom so late in the season as this one. This variety of the Loose-flowered Button Snakeroot, or Fine-leaved Blazing Star, by which the typical *L. graminifolia* is known in the United States, is among the best of a good but somewhat neglected group of hardy flowers. I do not suppose we are ever likely to become familiar with the *Liatrises* under the name of *Lacinaria*, favoured by our American cousins, but under whatever name we may grow them they are pretty plants. A nurseryman of wide experience once told me that the *Liatrises* prefer pure sand, but one at least, the popular *L. spicata*, occurs in moist soil in its native habitats. *L. g. dubia* grows, however, in sandy soil.

### CISTUS ALGARVENSIS OR HELIANTHEMUM OCYMOIDES.

ONE would be glad if the recent mention of this lovely plant, by Mr. A. T. Goodwin, should lead to its being more cultivated, although I am at present a little uncertain about its hardiness except in favoured places. I have thus not yet ventured to try it outside, but it makes a charming plant in a cold frame, where it is most beautiful with its silvery-grey foliage and pretty yellow flowers, each petal having a large spot of deep chocolate-brown at the

## HISTORY OF THE AMERICAN BEAUTY ROSE.

REFERRING to the answer to "H. L. Brown" on page 120 of THE GARDEN, August 16, it was my good fortune when in the United States of America to meet and chat with the man who gave the name to this Rose, and, to use his own words, "I made

base. According to the "Index Kewensis" this plant should be called *Helianthemum ocyoides*, but from a garden standpoint it is better recognised as a *Cistus*. A good bush of it in the open must be a glorious thing. The flowers are very fleeting, the petals falling to the ground in the course of the afternoon, and the bush is flowerless until the next morning.

### ERYNGIUM ALPINUM.

SOME Scottish growers of hardy flowers cannot understand why this fine Sea Holly does so badly in the South, and a remark by "G. J." in the course of a delightful article recently induces me to say that there is no difficulty with *E. alpinum* in the greater part of Scotland. It is no uncommon thing to see large clumps of it in gardens, and I know of more than one nursery where it is well grown without anything but ordinary care. There is, however, still some confusion about its name, and in not a few private gardens I have seen it named *E. planum*, a small headed species, in no way equal to the fine *E. alpinum*. The cooler conditions which prevail with us in the North seem to suit it well, but the curious thing is that it is not satisfactory at Edge Hall, a garden which, to say the least of it, is not one where there is either excessive heat or drought in almost any year. I do not think that it likes a very retentive soil, any more than it likes a very dry one.

S. ARNOTT.

*Carsethorn, by Dumfries, N.B.*

### ALPINE ARTEMISIAS.

If not so showy as many other Alpines, the above rank high among the most interesting of this class, being invaluable as plants for covering dry or exposed and unsightly spots on the rockery, walls, banks, or borders. The poorer and dryer the soil the finer will be the beautiful silvery or silvery white colour of foliage and stems, giving the whole plant most noble and distinctly uncommon appearance. All those enumerated are easily grown, and are quite hardy if planted in a suitable spot, but if planted in rich soil they grow most rank as long as fine weather lasts, suffering and growing wretchedly during damp and sunless weather, often disappearing during winter. Both the dwarfer, as well as taller growing kinds, also do well treated as pot plants, and the sometimes tender *Artemisia arborea*, which is, by the way, one of the best of the taller growing class, is very useful for conservatory decoration, provided it has always the necessary light, is not crowded in with other plants, and is carefully watered during the winter.

*A. nitida* or *A. pedemontana*, the hardiest and one of the best and most useful of the genus; with a fairly rapid growth it produces from a woody creeping stem several branches of prostrate habit and elegant pinnate, silvery white foliage. The flowers are globular, yellow, produced in racemes.

*A. Mutellina*.—This species and the next form are perhaps the prettiest of this class, which the German Tyrolese give the appropriate name of Edelraute. It has creeping or decumbent stems, and is of slow growth, forming with its pretty numerous silvery leaves, covered with silvery glistening hairs, a fine carpet; it does not lose its handsome appearance even during the dreary months of the year. The flowers are erect,

globular; the upper ones sessile, the lower ones racemose. When seen on the Alps (not by any means a common plant) at an altitude of 6,000 feet to 7,000 feet, but adapting itself readily to the climate of lower altitudes, as it is often found in the valley, it is most attractive to the eye, and it is feared that, like the Edelweiss, it will share the same fate of extinction at the hands of tourists. The flowers of this plant have a peculiar sweet scent, and are used for the flavouring of certain alcoholic drinks. Under culture it is not always a success. Planted in fissures, however, of rock, in peat and sand, and given a sunny position, it invariably thrives.

*A. Baumgartenii*.—A rare form of the former, its difference is principally in the arrangement of

In habit it resembles none of either the former or the following; it is without the glistening silvery white shine, but the colour of the foliage is a most snow white, while the flowers are small and yellow. A fine plant for sunny and dry spots.

*A. Villarsii*.—This has much longer leaves than *A. vallesiacum*, but resembles that species in everything else. A native of the Pyrenees of France.

*A. Roelzii* is from the Spanish Pyrenees. It has creeping stems of a decided silvery grey colour and yellowish flowers.

*A. spicata*.—A pretty plant with simple stems 4 inches to 6 inches in height. The foliage is sessile, finely cut, of a silvery grey colour, clothed with fine silvery hairs, the flowers being erect, globular, yellow, one of the few requiring quite the opposite treatment of most other species, thriving in a cool, fairly moist spot on shaded rock-work. Local on the Alps, Jura, and Carpathians, but quite easily grown.

*A. granatensis*, like *A. Mutellina*, easily grown, always developing well its handsome silvery silvery foliage.

G. REUTHE.

### TULIPA RETROFLEXA FOR NATURALISING.

IN reference to the article in THE GARDEN on "Naturalising of Bulbs in Grass Land" I should like to draw attention to the excellence of *Tulipa retroflexa* for this purpose. It comes up year after year with no signs (as yet) of deterioration, the flowers being perhaps a trifle smaller than those in cultivated beds, but not noticeably so. It is also in other respects a most desirable flower, very bright, showing up well at quite a long distance. I have had it growing in grass now for five years.

### TREES & SHRUBS.

#### THE ALDER.

**I**N view of the vast tracts of barren marshy ground, which in their present condition are yielding little or nothing to their owners in Great Britain and Ireland, the question may well be asked, Can nothing be done to reclaim such and render them both profitable and useful? It has sometimes been suggested to plant these places; at other times we are told that they are incapable of producing timber trees of a proper size to pay the expense incurred in the planting and yield a profitable return.

No doubt there are a few species

of trees unsuitable for planting in marshy ground, but happily there are several others that can be planted with success, and one of the best is the common Alder. This hardy native tree not only grows, but thrives in such ground,

and attains a useful size in a comparatively short time, and as its wood is keenly sought after and commands a ready sale, I can confidently recommend it to the notice of the planter. Although the Alder grows in marshy ground where few other trees can exist, yet to grow it successfully the ground should be drained as well as circumstances will allow.

Some places of this description are liable to be inundated by water for a considerable time

ALDERS IN MARSHY GROUND.

flowers and in the more elegant foliage. Mountains of Transylvania; rarely seen in English gardens.

*A. glacialis*.—A high alpine, although often found very low in valleys of the Central and Southern Alps. It is of low and slow growth, the stems, scarcely attaining a height of 1 inch to 2 inches, are covered with a mass of silvery, glistening silvery leaves, covered with hairs of the same colour. The flowers are golden yellow. A local but fairly common plant on the Alps of Vaud in Switzerland.

*A. nana*.—Another high alpine of very dwarf, slow growth, producing small silvery leaves without the characteristic silvery and hairy covering. The flowers are yellow.

*A. vallesiacum*.—A very distinct species with more finely-cut leaves of pretty silvery white colouring.

during winter. Such land, however, I have planted successfully during March and April, and when once the Alder gets established the annual flooding with water appears not to hurt the trees in the least. This class of ground varies so much in character that the mode of drainage must be settled in detail on the spot. In cases where there is a good outlet a single drain cut at the most advantageous spot will sometimes dry a considerable area, while at other times the drains require to be cut at a distance apart of 6, 9, 12, and 15 feet, the depth of these to be regulated in a great measure by the depth of soil above the water line. The soil excavated here should be spread over the surface, which will improve the texture of the ground and add a little to its depth. Ground prepared in this way may be either planted or the seeds sown broadcast upon the surface. The Alder is so hardy that self-sown seeds soon make fine trees. When once the trees are thoroughly established they make

The inferior, useless class of ground capable of growing the Alder to a profitable size, and the facility with which it can be established at small cost, either by sowing the seeds or planting, ought to induce landed proprietors to plant these barren bog lands with it.

W.

#### HYDRANGEA PETIOLARIS.

THIS charming shrub is better known under its old name of *Schizophragma hydrangeoides*. It is also called the climbing Hydrangea, but is shown in the illustration as a spreading shrub. The tall, somewhat slender stems send out roots which cling to the wall, and the whitish or pinkish flattened flower clusters, as shown by the illustration, are produced with great freedom. It is a native of Japan and has been introduced many years, but never seems to have become popular. Such a charming group, however, as that shown in the illustration

partial shade are often very large. The flowers, which come in clusters, are pure white, and often 2 inches across.

H.

#### SOUTH AFRICAN FRUIT CULTURE.

##### EXPORT AND LABOUR.

THE following accounts of the state of fruit culture and the "Labour Question" in Cape Colony are mainly compiled from the Government Reports, written by Mr. Eustace Pillans, which he was good enough to lend me for the purpose. The second article is a valuable paper by Mr. Pillans, which I have added in its entirety.

GEORGE HENSLOW.

##### THE HISTORY OF FRUIT CULTURE AT THE CAPE.

In the report of the agricultural assistant, Mr. Eustace Pillans, for 1893, he observes that the department had kept in view the necessity of introducing varieties of fruit not yet spread throughout the colony. Though it would have been better had they been introduced in the ordinary way of commerce, but it was necessary for the Government to take the initiative, so as to induce fruit growers to substitute good sorts for the prevailing "bastard seedlings."

The following were the principal items of importation for this purpose at that date: Two cases of the best Smyrna Fig cuttings, twenty varieties of Oranges and Lemons—350 examples in all—were imported from Naples. A small importation of bitter Seville Oranges was made to ensure getting an immediate supply of fresh seed, the object being to raise a better stock for grafting instead of using Lemon stocks as before for that object. A supply of pips for raising stocks for Apples, Pears, and Cherries were also secured.

On enquiry it was found that nearly all the best varieties of fruit to be found in the Covent Garden sales were already in the colony; but the orchards were not planned with the view of market production, being only, as it were, "amateur" gardens, containing a limited supply of one or two varieties each. This "old-fashioned, messy little way of orcharding," wrote Mr. Pillans, "must give way to orchards being measured

by Morgen, and not be a little back garden place behind a dwelling-house. By such means only can the orchardist hope to share in the fruit trade."

"The department enlisted the services of Mr. H. E. V. Pickstone, a skilled Californian orchardist, in order to give practical demonstration of the best methods of pruning fruit trees at such centres as should enable the greatest number of growers to attend and compare notes."

Since this was written the above experiment has proved the greatest success. Representative men have come from all parts during the past nine years, and 700,000 trees have been planted. In 1894 the Government planted 240 Pear, Apple, and Plum trees of pedigree sorts, and the best kind of stone fruits; but this was only a beginning, and far from being representative of all the fruit sorts suited to the Western climate and to the necessities of the exporter. From the small portion planted at that date large numbers of named scions

A LITTLE GROWN SHRUB: HYDRANGEA PETIOLARIS (SCHIZOPHRAGMA HYDRANGEOIDES) IN THE WOODLAND IN THE ROYAL GARDENS, KEW.

rapid progress, and in order to attain success the trees should be grown rather thickly. The planter's object should always be to produce fine clean wood, free of knots or blemish of any kind that would lessen its value in the market. I have sometimes found certain classes of home-grown timber to be rather a drug in the market at any price, but in all my experience I have never found any difficulty in selling a lot of really good Alder at a fairly remunerative price.

Although the Alder is highly suitable for planting in marshy ground, yet it is by no means confined to such, and can be grown to a profitable size on ground of ordinary texture, especially such as is of a damp character. I have grown some very fine Alder upon damp clay soil resting upon a cold clay subsoil, and as such land had failed to give a profitable return by tillage it was planted with Alder and Oak, both of which grew remarkably well, the former, however, giving by far the quicker and better return.

should do much to bring it under notice, and owing to its rambling nature it is a shrub for rock gardens and similar places, as well as in the woodland.

#### RUBUS NUTKANUS.

THE Rubus family is a most charming one, and *R. nutkanus* and *R. spectabilis* are happy among the natural vegetation of steep and stony banks. Those who wish to create pretty effects should make a note of them for planting in rough places, especially by woodland walks or in corners more or less shaded by large trees. *R. spectabilis* has flowers produced singly: they are large and of a purple-red colour. It grows vigorously, and has stout thorny shoots and large leaves, which are much like those of our native Bramble. The Nootka Bramble (see illustration) is of a different habit, being dwarfer, more bushy, but spreading freely into a handsome mass of leaf and flower. The leaves on plants in

were distributed for grafting and for budding. Under the heading of "Fruit Exports for 1894" Mr. Pillans observes that the farmers were becoming quick to recognise where their interests lay, for it was evidenced by the large extent to which certain kinds of fruit disappeared from the export shipments, and their place taken by others which were found to be better suited for transport and fetched better prices.

Mr. Pillans then refers to a serious drawback, viz., the pernicious custom whereby amateurs and outsiders took upon themselves to buy up job lots of fruit, pack them anyhow, and rush them on to the Covent Garden sales as "Cape fruit," to the utter ruin of whatever prestige our best fruits, selected and packed by the best men, may have previously gained.

Since the above was penned, at the present time, 1902, matters have improved, as it was soon found to be detrimental even to the "amateurs'" interests; but even now this has not been quite suppressed.

Mr. Pillans next calls attention to the rise of fruit growers' associations in the West; as he observes, the great thing to be avoided was the dead level of a stolid conservatism and satisfaction with the old unimproved methods practised from time immemorial. Perhaps the most noteworthy sign of improvement was the growing dissatisfaction with the average Cape seedling sorts, raised haphazard, the fruit of which, although lacking all the qualities that the buyer has a right to look for, was then still being sent to market, merely for what it would fetch. The miserable prices obtained for these inferior qualities failed to cover the rail, and he adds that it was more than probable that the improvement signalled in 1894 was due rather to a spirit of emulation, for which thanks were due to the associated meetings and the public exhibitions.

In his report for 1895 Mr. Pillans alludes to the results of the planting really good sorts of trees in the Government grounds.\* This growth was most satisfactory. Farmers, not only in Cape Colony, but in the Orange River Colony and the Transvaal, began the practice of sending unknown fruits for determination. Moreover, a strong feeling was rising against the propagation of the nameless seedlings of inferior qualities which had hitherto been so common everywhere.

\* In this climate young trees blossom and fruit in the fourth or fifth year.

He also records the fact that in 1895 there was a perceptible improvement in the stocks of fruit exhibited for sale in Cape Town; though there was not then, nor is there to-day (1902) any serious attempt to improve the dessert forms of Grapes. Indeed, in 1895 there was no improvement in dessert fruits other than Grapes.

Unmistakable signs of improvement were to be seen in 1895 in a few private establishments. In one—that of Messrs. Malleon and Dicey at Hex River—

200,000 selected orchard trees were planted, and

without deriving any

In his report for 1896 Mr. Pillans mentions that additional ground on the Government property at Constantia was planted with the best kinds of Pears.

It must be borne in mind that the climatic conditions of the eastern side and of Natal are very different from the western, so that Mr. Pillans wisely called the attention of the Government to the desirability of establishing at least two typical orchards in the eastern province, namely, one for the coast level at or near East London, and one for the higher plateau, preferentially at Queen's Town. These were established, and at the present time (1902) have proved to be very successful and useful. The plan adopted was as follows: A portion of unprepared or wild ground was rented of the owner by the Government for ten years. The lessee undertook to fence, clean, trench, plant, and prune the trees. The amount was five acres. After four years the trees began to bear. The owner—who undertook to keep the orchard clean, and to allow access to all the farming public to inspect and learn from the cultivation—was entitled to the fruit, and the whole finally reverted to him. The total expense to the Government was covered by £300.

The following contributions to the *Cape Times* and *Argus* during March of this year are here inserted as bearing upon the subject of this paper:

#### VITICULTURE AT THE CAPE.

The most important agricultural pursuit in Cape Colony has, until late years, undoubtedly been viticulture for the purpose of wine-making. We must go back to the middle of the seventeenth century for the earliest days, when we find that the Muscatel Grape was used in 1681. The first brandy was made in 1687, the total number of Vines in cultivation in the settlers' vineyards and those of the Dutch East India Company being upwards of half a million.

The Huguenot settlers gave an impetus to viticulture after 1688 by introducing greater skill in the art of wine making and in increasing the varieties of wines of superior quality. As the Vines came from the South of France the Grapes were especially rich in sugar.†

Hence the Cape became famous for its sweet wines, and "Sweet Constantia" became a favourite in London. It is only recently that some of the less sweet northern French varieties

NOOTKA BRAMBLE (*RUBUS NUTKANUS*). (From a drawing by H. G. Moon.)

assistance from the Government. As another instance, Mr. P. J. Cillee, of Wellington, devoted himself to the Prune industry. The trees were supplied by Mr. Pickstone, who revolutionised the old order of things, and established in the Colony what did not exist before, viz., a nursery capable of dealing with the prospective fruit farm demand.

† The climatic conditions, which resemble those of the South of Spain, and also the system of short pruning, *en gobet*, have no doubt a certain amount of influence in developing sugar.

from which light wines are made have been introduced. They were used for sherries, and required fortifying with spirit to ensure keeping.\*

In 1710 the Vines amounted to nearly 3,000,000, but in 1891 there were 78,500,000, yielding nearly 5,000,000 gallons of white, 1,500,000 gallons of red, and 1,500,000 gallons of brandy. Raisins also amounted to 2,500,000 lb.

It is in the drier western province where the vineyards are, the Vines resembling small Currant bushes of English gardens, the climatic conditions being perfect. The soil is mostly decomposed granite on the slopes of the mountains, but in lower situations there is a deficiency of lime. The product of the vineyards of the Cape is said to surpass as to quantity and quality that of any other wine-producing country in the world. Europe's yields vary from 14½ to 42 hectolitres per hectare, whereas in Cape Colony Coast Department these amount to 86½, and inland to 178.

The Groot Constantia Wine Farm is a centre where everyone interested in Grape growing may see the newest processes in operation. It was bought by the Government and managed by a colonial, who has brought the vineyards to a high state of efficiency. It is a financial success, and is rapidly becoming a centre of instruction in new and improved methods of working. This wine farm consists of about 300 English acres; fifty acres are under vines, and about thirty are under general cultivation. The best varieties of European Vines are now all grafted on the phylloxera-proof American stocks. The wines made are six in number, two white, two red, and two sweet wines. The best stored wine is now valued at £1 10s. per leaguer, instead of £5 and £6, common prices in 1893.†

(To be continued.)

## THE FERN GARDEN.

### A LEMON-SCENTED FERN.

THE MOUNTAIN LASTREA (L. MONTANA SYN. OREOPTERIS).

**I**T is a very curious fact that this Fern, despite its extreme abundance in many parts of Great Britain, is one of the rarest of all in culture, and yet it is in many respects one of the most interesting Ferns we have, and has yielded a great range of beautiful varietal forms. In the first place, it is one of the few Ferns existent which has a really pleasant odour, strongly reminiscent of Lemons, whence its popular name of the Lemon-scented Fern. Although mainly a denizen of mountains, or, at any rate, hilly districts, it is by no means restricted to such, as we have ourselves found it in Epping Forest and also in Kent in quite lowland situations, while in our western counties it fringes the lanes in quantity. It is, however, on the hill-side, bordering the slopes of mountain streams, or on rougher and drier ground, with projecting rocks interspersed, that we find it in quantity pushing up its clumps of pale yellowish green fronds in profusion. At first sight it bears some resemblance to the common Male Fern, growing as that does in shuttlecock fashion from central crowns, but, apart from its different tint and characteristic odour when passed through the hand, it differs from that species by its lanceolate bipinnate fronds having no naked stalk at the bottom. The Male Fern has a frond commencing some distance up the stalk, with longish side

divisions, imparting somewhat of a trowel shape to it, but *L. montana* begins with rounded lobes right at the base, and these gradually lengthen for two-thirds of the length, and then taper gradually to the tip.

On examining the fronds with a lens they are seen to be sprinkled with tiny yellow-stalked glands, and it is these which yield the perfume when bruised by friction. The spore-heaps are more numerous and smaller than in the Male Fern, from which, however, it is easily discriminated by the frond formation.

#### TASTES AND ANTIPATHIES.

It is generally assumed to be little amenable to pot culture, but we find that with a little attention to its particular tastes it does very well in pots, and, probably from its odour and perhaps from its flavour, is peculiarly immune from the attacks of vermin. As regards its particular tastes it differs from most Ferns in liking a pure yellow loam of a friable, crumbly nature instead of the usual compost of loam and leaf-mould. As we have seen, it is by preference a hillside and not a wood Fern, and this implies good drainage. Its antipathies are lime or hard water containing lime and drought at the roots. Dry air it can stand, as its natural habitats imply, but drought at the root is fatal. If, therefore, we plant it out of doors we must give it an open, loamy station in a position where it gets plenty of light, but is not subject to drought, while in pots, given the proper soil and good drainage, it will hold its own well. It is thoroughly deciduous, the fronds dying quite down to the ground in the autumn even under glass, hence a good plan is to bury the pots outside in the soil for the winter, mulching them lightly with the old fronds or a little leafy debris. As regards propagation, it is a particularly difficult Fern to raise from spores, few growers succeeding, a singular fact when we consider the multitude of self-sown seedlings which we may find in the chinks and crevices of its native rocky habitats.

#### A VALUABLE HINT.

We have, however, discovered that the old clumps of roots, or rather root-stocks, if kept close and damp have a peculiar faculty of developing young plants from bulbils in a remarkably short time. On two occasions we have found very fine varieties—*L. m. cristata* Drury and *L. m. plumosa* Drury. The first was a huge clump, and when we divided it up for distribution—it had thirty-three crowns—we threw the mass of old and apparently dead root-stock into the corner of a Todea frame, where in a few weeks it became literally green with a grass-like crowd of typical youngsters. The second find, in August last, only afforded a small piece of such unpromising material, but as we write (at the end of September) fine plants have appeared from pimple-like buds developed on the caudex. The abundance of the common or normal form renders such trouble needless, but it is otherwise with the splendid varieties, crested or tasseled, plumose or finely-cut and foliose, dwarfed and congested, twisted and curled which have turned up to reward the Fero hunter, and which, as we have said, are difficult to raise from the spore, hence this hint is valuable though quite accidentally suggested.

#### VARIETIES.

It is remarkable that in the first half of the last century, although *L. montana* was well known as a species and was presumably subjected to the same search for varieties, the quest was so badly rewarded that it gained the character of being one of the most constant Ferns we have. Then, however, Mr. W. M. Barnes and others in the Lake District, where it is peculiarly plentiful, discovered one or two good things, and, encouraged by their success, prosecuted the search so assiduously and so successfully that eventually it turned out to be one of the most sportive, several scores of very distinct and fine forms being added to our collections as wild finds, while in the skilled hands of Mr. Barnes a few improved crested types were acquired in addition. This being so, we strongly counsel greater attention being given to this species, since there are many situations on gentle-

men's estates and in private gardens where it would thrive out of doors or indoors, and where a collection of good types would undoubtedly "pay its rent" in the shape of interesting attractiveness.

CHAS. T. DRURY, F.L.S., V.M.H.

## GARDENING OF THE WEEK.

### THE FRUIT GARDEN.

#### PEACHES AND NECTARINES.

**N**OTWITHSTANDING that these fruits were later than usual this season, all but the very latest are now gathered. The nets may be removed, and all shoots cut away that are of no further use. This will the better expose next year's bearing shoots to the sun and air, and by lightly passing a Birch broom over the leaves as soon as they are matured they will readily fall, and the wood will be benefited by full exposure. This is a suitable time to renovate defective borders and also to lift or prune roots that are causing mischief through having penetrated too deeply into the borders. Instructions were given in a former calendar for carrying out this work. The planting season is close at hand, and planting should be carried out as soon as the trees have lost their leaves, or, in the case of those that only have to be moved from one position to another in the same garden, as soon as the leaves begin to fall. The importance when planting trees of spreading the roots in layers near the surface of the border, making the compost firm about them, loosely securing the trees to the wall or trellis so that they settle with the recently disturbed soil, and lightly mulching with short litter should not be overlooked. Outdoor Peach and Nectarine culture deserves more attention than it receives, and we find in low, moist situations that it can be more successfully followed than can Apricot culture.

#### GATHERING FRUIT.

The gathering of Apples and Pears will now call for frequent attention if each variety is, as it should be in order to have it in its best condition, gathered at the correct time. The time to gather can be easily ascertained by gently lifting the fruit to a horizontal position, when the stalk will readily sever from the tree if it is in a fit state to gather. For storing purposes the fruit should be gathered when it is perfectly dry, and unsound specimens be separated from the bulk and first used. Every necessary care should be taken not to bruise the fruit, and for this reason the baskets should be lined with wood wool or some similar material. Late varieties of both Apples and Pears should be allowed to hang upon the trees as long as possible, otherwise their value will be greatly impaired through shrivelling. The Pear Flemish Beauty, however, must be forcibly removed from the tree in order to obtain its best quality.

#### STORING FRUIT.

Much depends upon the fruit room and the system of its management as to how fruit keeps. It should be carefully ventilated until the sweating has passed, when it should be closed, although air must be admitted on occasions. It should also at all times be kept dark, cool, and of an equable temperature.

T. COOMBER.  
*The Hendre Gardens, Monmouth.*

#### INDOOR GARDEN.

#### THE PLANT STOVE.

MANY plants in this structure will benefit now by a thorough overhauling and cleansing. Where labour cannot be spared for sponging I have found the following mixture a check for mealy bug, and it will also impart a glossy appearance to the leaves:—Boil 1lb. of soft soap for about ten minutes in one gallon of soft water. Use half a pint of this mixture in four gallons of water, adding 8ozs. of petroleum. Lay the plants on their sides and thoroughly syringe the foliage. Sufficient fire heat will be required in order to maintain a night temperature of 60° to 65° and a day maximum of 70° to 75°, allowing the temperature to rise with

\* Taken from Wallace's "Farming Industries of Cape Colony," 1896.

† The four best prices in the present year (1902) are as follows: Hermitage (a red "claret"), £1 6s.; Cabernet Sauvignon (a red "Burgundy"); Sauvignon Blanc (a "Hock"), £1 6s.; Sweet Constantia (a liqueur), £1 10s.

sun heat. Allamandas, Bougainvilleas, &c., passing out of flower must have less water, as they require a rest to enable them to start early next season.

#### CROTONS.

From plants having served their purpose for house decoration cuttings should be struck. The varieties with broad leathery foliage are the best to withstand a prolonged stay indoors. The narrow leaved varieties are never so satisfactory, especially in winter. The pots should be full of roots, and the plants be prepared for the change by gradual transfer through lower temperatures in order to withstand the rough treatment they may have to endure.

#### DRACENAS

should be treated somewhat similarly. Brilliantly coloured varieties have generally a weaker constitution than the green-leaved sorts. Sucker growths of

#### PANDANUS VEITCHI

should be taken off when they can be obtained and potted up in an open porous compost of sandy

by making rough shelters such as skeleton frames either with timber or turf on a southern aspect, and every available foot of space will be well occupied in this way. Protecting material, especially dressed canvas covers, ward off severe frost, and practically keep the crops safe against an ordinary winter, and after filling the cold frames, which in many places are none too plentiful, choose fine weather, and prick out fairly thick such as late sown Endive, Lettuce, Parsley, Red and White Cabbage, Cauliflower, and the like. Lift fully-grown plants of Endive and Lettuce into good balls of soil when quite dry and place in cold frames, cool orchard houses, or even open sheds, when they may be blanched as required.

Continue to earth up and blanch Celery, Leeks, and Carrots during the middle part of the day when dry. Spare no pains to break up the soil finely, and place it firmly round the growth of the first-named, as by so doing the keeping qualities will be much more certain. Make sure before doing so that the roots are in a thoroughly moist condition, as good Celery cannot possibly be expected when allowed to suffer for the want of water. Early Celery in many places has run to seed this season, and in some places, I am sorry to say, to an alarming extent, even when every possible attention has been given. Generally speaking this is caused through a check of some kind, and no doubt in this case it was owing to the ungenial weather which we experienced after the plants were put out into the trenches.

#### TOMATOES.

Plants which have been treated for bearing during the winter should now be strong and sturdy and well established in their fruiting pots. These will have been brought forward in cool houses, and should now be placed in heat; this should be done gradually, getting them acclimatised to their new position as gradually as possible, and endeavour to keep the growth short jointed, and the foliage and the atmosphere of the

stored in quite cold places; also Vegetable Marrows and Globe Artichokes, which will much prolong the season. Sow frequently small salads in boxes under glass.

*Aldenham House Gardens, Elstree.*

## NEW AND RARE PLANTS.

### A NEW LILY OF THE VALLEY.

CONVALLARIA MAJALIS PROLIFICANS.\*

**W**E have written more than once about this new Convallaria, and now offer our readers an illustration of it with the following description. The illustration shows a pot of the Convallaria, and the plants are numbered. No. 1 is a common spike flowering with bunches; Nos. 2 and 3 are young small plants flowering commonly without bunches, but the few well formed flowers are usually of a size not hitherto seen, and there are twenty flowers on one stem. On a flower-stalk of No. 2, which stands behind No. 4, nineteen flowers can be seen. No. 3 is rather stronger; in the place of the lowest flower a small cluster of flowers is already formed. No. 4 is a weak plant, but is flowering with two flower-stalks, whereon are bunches of flowers. No. 5 is a plant with two flower-stalks flowering as before without leaves, which may often be seen; the leaves are in this case growing very slowly. In Nos. 4 and 5, both bunch-flowering, the flowers are not yet open. Of No. 4 the flower-stems may be seen with difficulty. The flowers, which are milky white, have a very strong and delicious perfume. The illustration gives a general view of this new but remarkable Convallaria, which, when more cultivated and improved, will very probably produce still larger flowers and heavier flower-stalks, and in 1903 the Convallaria majalis prolificans Vrengdenhill Perfection may be at least twice as strong as now. This Convallaria is well suited for decorations; the flower-clusters of strong plants can be separated from the flower-stalks and used separately for decorative work, bouquets, &c. One flower-stalk of such a strong plant is in itself a bouquet, and where now three or four sprays of the common Lily of the Valley are used for a button-hole, one flower-stalk of this New Perfection will in future be quite enough.

For the present this illustration suffices, because flowering crowns are not yet strong enough to make good pictures, and because this variety will be still further improved in each successive year, and therefore a complete collection of pictures of it will be made in 1903 and 1904 and offered for inspection. The flowers are already, considering the circumstances, unusually fine. This New Perfection, Convallaria majalis prolificans, Mr. J. Vrengdenhill considers to be a useful market plant.

—J. VRENGDENHILL.

### RECENT PLANT PORTRAITS.

THE Botanical Magazine for October has portraits of the following plants and flowers, mostly bloomed at Kew:—

*Streptocarpus Mahoni*.—Native of British Central Africa. This is a beautiful and free-blooming species allied to *S. Saundersii*, and producing bunches of bright blue flowers somewhat resembling those of a large Lobelia.

*Anemone cernua*.—Native of Manchuria and Japan. This is a curious species, with nodding reddish brown flowers, introduced to cultivation by Herr Max Leichtlin, of Baden-Baden.

*Masdevallia schroederiana*.—Native of Peru. This is also known as *M. fulvescens*. This is a singular and rather highly-coloured variety of this curious family of cool house Orchids.

\* Translated from the *Weekly Floral Paper for Flower Bulbs, Cultures, &c.*, of June 14, 1901, Haarlem, Holland.

A NEW LILY OF THE VALLEY (CONVALLARIA MAJALIS PROLIFICANS).  
(Half natural size.)

loam and charcoal, and plunged in a propagating frame with a good bottom heat, where they will soon root.

#### SUMMER-FLOWERING CHRYSANTHEMUMS.

Plants that have finished flowering should be cut down and placed in a cool light pit or frame to encourage them to grow away freely and make a clean strong sturdy growth. Weak drawn-up cuttings seldom produce good plants or blooms. Late decorative varieties, specially grown for giving a display at Christmas and onwards, should be arranged in a light cool house or pit, and given air whenever the weather is favourable.

JOHN FLEMING.

*Wexham Park Gardens, Slough.*

### THE KITCHEN GARDEN.

EVERY preparation must now be made to ensure the safety of the more tender kitchen garden crops against severe weather. Very much may be done towards this end, even without the aid of glass,

houses should be kept as dry as possible, and air more or less should be given every day, and to ensure a free set the flowers should be fertilised daily. Water at the roots should be given only when the plants absolutely require it, and this at all times during the winter months should be warmed to the temperature of the house. Plants which are in full bearing should also have the temperature increased, and the fruit as soon as it shows signs of colouring should be cut and placed in a warm temperature to finish ripening. Any plants which still have fruit on them outside should now be pulled up, and unless the fruit is colouring it is a capital plan to take off the foliage and hang up the plants head downwards in the warmest place available, under glass for preference. The fruit will derive much benefit from the nourishment stored up in the growth, and the quality will be much better than if cut and coloured direct from the plant.

With any signs of frost see that the heads of Cauliflowers turning in are well protected. All French and Runner Beans should be picked and

*Gloriosus Mackinderi*.—Native of British East Africa. A very bright-coloured and beautiful variety with medium-sized flowers. Seed was sent to Kew from Mount Renia in 1900, which bloomed in a greenhouse in 1901.

*Iris Leichtlini*.—Native of Bokhara. A curious and beautiful variety closely allied to *I. Eulefeldii*, with brown and rosy purple flowers.

The first number of the *Revue Horticole* for October contains a portrait of the beautiful tailed Butterwort *Pinguicula caerulea*, with large rose-coloured flowers. I think, however, that I have seen them of a much deeper and finer shade of rose than here portrayed. It is not hardy in this country, requiring the protection of a greenhouse. The October number of the *Revue de l'Horticulture Belge* has a good double plate of an ornamental tender Fern named *Davallia bullata*.

W. E. GUMBLETON.

### APPLE ROYAL LATE COOKING.

THIS Apple, of which we give an illustration, was raised at the Royal Gardens, Windsor, many years ago, and was only known locally until exhibited at one of the Royal Horticultural Society's meetings. Its fruits were then recognised by the fruit committee, who gave it an award of merit. Since it has gained much in popular favour, and is now admitted to be amongst the best of our late winter culinary Apples. It has also been well spoken of as a dessert variety late in the season when dessert Apples are scarce. It is much superior in flavour during March and April to any of the imported Apples then sold as dessert varieties. The fruit is large and greenish yellow in colour. The flesh is tender, juicy, and sweet. The tree is hardy, strong, and sturdy in growth, and bears freely as an orchard or a garden tree. It is one of the latest varieties, keeping well until Apples come again, and when better known will become a great favourite.

APPLE ROYAL LATE COOKING. (Two-thirds natural size.)

hasty glance could be taken at the fine collection of hardy plants, but I was glad to see by a few blooms still remaining on Hollyhocks that the strain grown is an excellent one for garden use.

It is not of the florist's type, in which the individual flowers are so tightly packed with petals that they are like round balls, and that the play of light within and among the petals, which gives richness of colour, is lost, but these have the distinct guard petal which adds much to the beauty of the flower, and the rather looser inner petals with the glowing colour gained by their more free disposition.

There is a fine strain in these grounds of the useful mahogany-striped autumn-blooming *Helenium*, known as *Helenium grandicephalum striatum*. The dark striping is more conspicuous and of better colour than in the usual variety. The value of *Chrysocoma Linosyris* (now classed among *Asters*) as a showy autumn plant was well proved by a handsome patch. The hardy Fuchsias were in quality and extent of the collection.

### DAHLIAS AND HARDY PLANTS AT

MESSRS. CHEAL'S NURSERY AT

CRAWLEY, SUSSEX.

AVISIT to this excellent nursery cannot fail to be a pleasure and an advantage to all who value good garden flowers and shrubs. My visit was a little late to see the Dahlias at their best, for lying, as the nursery does, on the level land of the weald of Sussex, the recent frosts, that had spared us dwellers on the sandy hills, finding us dry and therefore less vulnerable, had destroyed much of the foliage and bloom of Messrs. Cheal's Dahlias, though enough was left to show the fine quality and extent of the collection.

Among the Cactus Dahlias, some already well known on the show tables were conspicuous for quality and freedom. The sharp pinch of frost had served one useful purpose, that of proving comparative hardiness, and some of the best kinds for colour and quality proved to be among the hardiest. Mrs. Mawley, of clear lemon colour, was one of the best; other beautiful flowers were Mrs. McKergow, buff-apricot; Floradora, blood-crimson; Regulus, crimson; Countess of Lonsdale, copper-salmon; and Alfred Vasey, salmon-apricot, a very free bloomer. Mrs. A. Perkins, lemon and white, is a very pretty flower.

They are delightful plants of latest autumn that should not be neglected by those who have gardens anywhere south of London. On the South Coast and the best climates of the British Isles they are hardy, and form large bushes, growing from old-established wood; but elsewhere they do excellently treated as herbaceous plants, cut down after flowering and growing afresh every year from the root. The four most useful are Riccartoni, gracilis, globosa, and exoniensis.

Time, unfortunately, did not allow of an examination of the shrub and hardy fruit quarters for which this nursery has so high a repute.

### ARTIFICIAL MANURES IN THE GARDEN.—III.

If the hints given in the preceding articles have not missed their mark two things will have been made clear—(1) that the economical use of artificial manures means the application of the particular substances called for by the crop grown and needed by the soil in which it is growing; and (2) that the use of special manures—that is to say, manures specially mixed for certain crops—may often be exceedingly expensive, though it is certainly very frequently a great convenience. On this point a good deal more might be said, but the illustration given in the issue of June 7, which is a typical one, ought to be sufficient to prove the statement. The manure referred to is expensive, even if the soil and crop imperatively call for the ingredients supplied, while if any of them are unnecessary their use is, of course, unprofitable.

The next point of interest is the method of using these manures. It has been pointed out that the use of the expensive nitrogenous manures is not necessary in the case of plants belonging to the order leguminosæ. This curious fact is of comparatively recent discovery, though the practical fact that Clover (a leguminous crop) always left the land on which it was grown in good condition has long been known to farmers. Except in the early stages of growth then, when the power of absorbing nitrogen from the air has not yet been acquired by the plants, there is no benefit to be derived from the use of sulphate of ammonia or nitrate of soda. But in all other cases these manures are of great value in stimulating growth, and they fully merit the high esteem in which they are held by gardeners and farmers. In the case of such crops as Onions, Leeks, Cabbages, and Greens generally, and any crop in which vigorous growth of the leaf or "body" of the plant is desired, nitrogenous manures have a most beneficial effect, and the result of an application is often so marked as to seem marvellous. The proper time to apply it is when the plant is in active growth or just before this stage is reached. There is no loss in giving sulphate of ammonia a little earlier, but nitrate is extremely soluble, and if a period of wet weather followed on the application, and the plants were not in such a state of growth as to be able to take it up, it is probable that a large portion would be washed away out of the reach of the roots and so be absolutely lost to the cultivators. The results following small applications of these manures to greenhouse plants and flowers generally are so well known that nothing need be said on this head.

Phosphatic manures are more specially necessary for root crops, such as Turnips, Carrots, Beet, and Parsnips, but there are few vegetables that are not the better for an application when the supply in the soil is not ample. Of potash manure we have already spoken; if the claims of its advocates are well founded the views formerly held concerning it will have to undergo considerable modification, for experiments tend to show that even on soils where, theoretically, there are ample supplies of this ingredient, a dressing of kainit or muriate of potash has the effect of increasing the crop considerably. It is certainly much called for in the case of Potatoes, and, like phosphates, is beneficially applied to Peas. The time to apply it is early in the year, or even in the autumn previous. There is no advantage in giving very heavy doses of artificial manures. In the case of flowers there is grave danger of injury from the excessive use of nitrogenous dressings, and care is necessary—small doses given frequently are infinitely superior to a large quantity applied at one time. Further, even when no injury results, the manure given in excess would, as pointed out earlier, be washed away and lost. In the case of phosphatic and potassic manures the same thing does not hold good. They would still remain in the soil and be

G. J.

available for another crop, but there is no reason why the money spent for them should not be kept in the pocket until they are needed. Gardeners do not measure by the acre, but as a general rule it may be stated that the dressings of nitrate of soda or sulphate of ammonia vary from 1cwt. to 3cwt.; of superphosphate, 3cwt. to 5cwt.; guano, 1cwt. to 3cwt.; kainit, 2cwt. to 3cwt.; and muriate of potash, 1cwt. to 2cwt. For convenience sake, when dealing with small areas, a dressing of 1½cwt. may be considered as amounting to 1lb. to the square rod (5½ yards by 5½ yards).

W. Y. N.

## ORCHIDS.

### ODONTOGLOSSUM CRISPUM VAR. LUCIANI.

**A**CUT spike with four flowers of this grand variety was shown by Mr. A. Warburton, Vine House, Hasleden, Lancaster, at the Royal Horticultural Society's meeting on June 10. It received a first-class certificate in March, 1897, when shown by Mr. Linden, but since then the flowers have improved in size and substance. The ground colour is white, with large blotches of claret-purple, the colour showing dark purple through the back of the flower. In point of value it is the highest priced Odontoglossum yet sold. One plant recently changed hands for the record price of 700 guineas.

### NOTES FROM THE DELL.

(THE RESIDENCE OF BARON SCHRÖDER.)

A MORE interesting and charming garden than that at The Dell, the residence of Baron Sir J. H. W. Schröder, Bart., C.V.O., it would be difficult to find. The collection of Orchids is of world-wide fame. No other contains so many rare or valuable kinds in such abundance; in fact, many Orchids are at The Dell which importers can never hope to obtain again. In the Orchid houses plants of more than ordinary interest, apart from their intrinsic value, are in every department. In the warm *Dendrobium* house the original varieties of *Dendrobium Phalaenopsis schrederianum*, first sent home by Forbes, are now in bloom. Since Baron Schröder first acquired these plants through Mr. Lee's sale they have flowered annually, and curiously enough, in spite of the immense numbers imported, on the rediscovery of this fine Orchid by Sander, of St. Albans, and subsequent consignments, these plants are among the finest varieties known, rivalling and even surpassing the best forms in colour, size, and substance. Forbes originally is supposed to have sent but two plants, which found a place in the Kew collection, but by some means Mr. Lee, of Leatherhead, acquired a plant or plants, and on the sale of that gentleman's stock they were acquired as stated.

In another house are some grandly flowered examples of *Dendrobium formosum giganteum*, the largest and finest variety of the true type. The huge shining snow-white almond-scented blossoms are most effective, particularly when the plants are disposed as at The Dell. Many

of them are simply attached to pieces of wood surfaced with sphagnum.

One of the large *Cattleya* houses—a lofty structure—contains a specially fine assortment of *Cattleyas*, *Laelias*, and *Laelio-Cattleyas*. At this season comparatively few are open, but from the numerous sheaths on the *Trianae* and *labiatae*, &c., there will soon be a good display. A magnificent specimen of *Sobralia macrantha alba* also forms a feature in this house, as does a large and handsome plant of *Cattleya bicolor*, well deserving a varietal name, as it is probably the best variety in cultivation, with substantial buff-orange sepals and petals and a broad massive lip of crimson amethyst.

A narrow lean-to house leading to the cool houses contains a representative selection of Vandaceous plants, superbly grown, with leafy stems. Among them can be noticed the best varieties of *Vanda suavis* and *V. tricolor*. It is a pity that this class of Orchid is so unaccountably neglected by many Orchid lovers. They are easily grown, are constantly in flower, and the glossy foliage renders them attractive at all seasons of the year.

Want of space precludes a detailed description of this incomparable collection. Rare forms can be seen on all sides intermixed with splendid specimens of *Oncidium macranthum*, *loxense*, *serratum*, *superbiens*, &c., *Odontoglossums* *Edwardii*, *ramosissimum*, and the unique *O. liliiflorum*.

with huge leaves like an elephant's ears, the bullate surfaces of hoar silver broken by divisions of olive green; *New Beauty*, dark velvet green, shaded with crimson and zoned with silvery white; *Silver Mammoth*, with huge shapely leaves of shining silver white softly relieved with rose; *Ibis Rose*, best described as rose-pink in colour, but glistening in certain lights; *Helix*, with curiously-shaped attractive foliage, the basal lobes circling round and round in a corkscrew-like form; *Silver Grey*, olive green, with an intermediate zone of silver-grey, the ground colour powdered with silver; *Comtesse de Tellerson*, with foliage in varying shades of green, from a soft emerald tint to deep olive. A house devoted to *Nepenthes* cannot be passed over, on account of the size and rich colouring of the pitchers and the number covered by each plant. Fine varieties of *Nepenthes mixta*, *mastersiana*, *Chelsoni*, *Curtisii*, *rafflesiana*, *northiana*, &c., are particularly conspicuous. It must not be imagined that the glass houses alone receive attention at The Dell.

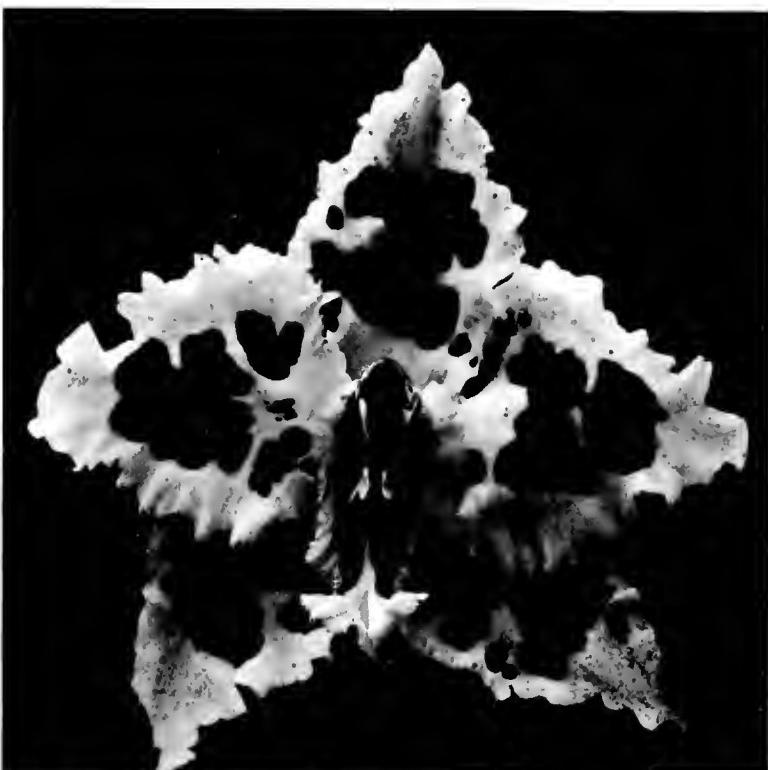

Thoroughness in every gardenering detail is an essential at this charming place, and though the acreage of the outdoor grounds cannot be called large, so effectively are they planted that their extent appears to be more considerable than it really is. Each shrub and tree is a perfect specimen of its kind, and so placed as to display in full its particular characteristics and beauty.

Rhododendrons are in profusion. A huge bank of them encircles a great part of the garden, with the choicest varieties as isolated specimens. The well-kept lawns are planted with specimen Conifers, including grand pieces of *Cedrus Deodara* and *C. atlantica*, clothed from bottom to top. Two splendidly grown trees of *C. Deodara alba spica* are prominent by reason of their size and great beauty. Cedars of Lebanon were also noticed, and a superb plant of the Japanese Umbrella Pine (*Sciadopitys verticillata*). A rather sheltered position has been given it. Superb Hollies are also a speciality at The Dell—a more uniform and beautiful set of plants it would be hard to find. The choicest variegated forms, silver and golden, are admirably foiled by the green kinds with which they are intermixed.

The rock and alpine gardens are full of the choicest hardy plants appropriate for this fascinating branch of gardening. This department, as all others, is beautifully kept. Unfortunately, in brief notes such as these, it is impossible to do even bare justice to this excellent garden, so admirably managed by Mr. H. Ballantine, the kind and genial head gardener. Situated on the borders of Berkshire, it is placed amid some of the most beautiful natural scenery in England. One aspect calling for especial mention overlooks Windsor Forest. The undulating ground forms a

natural dell, and is thickly covered with Bracken, Oaks, Hawthorns, Hollies, &c.

ARGUTUS.

FLOWER OF THE FAMOUS ODONTOGLOSSUM CRISPUM VAR. LUCIANI.  
(Natural size.)

Among the crispums, *O. c. apiatum* was pointed out, a nice healthy plant in the best condition; also *crispum*, The Dell variety, *c. schrederianum*, &c., together with *Pescatorei schrederianum* and *P. vitchianum*.

A marked feature in the cool houses, and one which might be followed with advantage in every similar place, is the presence of numerous Begonias of the Rex type planted beneath the stages and along the edges of the paths. That both position and temperature suits them is obvious from their vigour and luxuriance, and their brilliant colours add immensely to the attractiveness of the houses. Mention in particular may be made of *Begonia Tresco Abbey*,

**When to plant the Larch.**—Old-World foresters tell us that the Larch is one of the easiest trees to transplant of the many they handle, and such is the experience of plauters here if the trees be set at the right time, which is early in autumn or very early in spring. If deferred in spring until the buds burst planting is very risky. In my own case, had I some of the trees to plant, I would do the work towards the close of this month—September—planting carefully. Pruning is a great help, and of no loss to the tree, which grows the bushier for it.—*Florists' Exchange* (New York).

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

## A WHITE CAMPANULA IN PAVEMENT.

[To THE EDITOR OF "THE GARDEN."]

**S**IR.—I am sending you a photograph of a plant of the lovely *Campanula pyramidalis alba*, which is growing in the garden of a friend of mine (Mr. Freestone, the postmaster of the village here) who is a most enthusiastic amateur gardener. What makes this plant so interesting in its present position is the fact that

A BELL-FLOWER (*CAMPANULA PYRAMIDALIS ALBA*)  
SEEDLING IN PAVEMENT.

it is growing on a close pavement of blue brick as will be seen from the photograph, and is self raised. Undoubtedly the seed was carried (from parent plants growing in the garden) either by the wind or by birds, and found a lodgment in the joints of the brickwork and germinated there, which took place during the summer of last year. Beyond taking care that it should not be eradicated as a weed, the only attention the plant received has been to secure the growths to the pillar of brickwork between the two doors, and to throw down a little extra water when the pavement has been washed down, which latter falls sharply away from the house. It has formed a very pretty picture growing in so conspicuous a position,

and I have seen many poorer specimens of this beautiful plant grown in pots for conservatory decoration.

F. J. CLARK.

Wistow Gardens, Leicester.

## BULBS AND OTHER PLANTS FROM ABROAD.

[To THE EDITOR OF "THE GARDEN."]

SIR.—The editorial leader on "Bulb Growing in England" in THE GARDEN of the 20th ult. serves to direct one's attention to the large sums we pay the foreigner for different plants, many of which might be equally well grown in this country, whilst on the other hand there are some that try as we might would not prove a remunerative crop. For instance, the value of the Bermuda-grown *Lilium Harrisii* is owing to the fact that the bulbs are ripened and reach this country when the plants out of doors here are still green. English summers, too, would not suit the Tuberose, which comes to us in large quantities from the United States, and in a much lesser degree from South Africa. The last-named as a rule reach here in early autumn, while the American ones seldom arrive before Christmas. Again, *Lilium auratum* is commercially a failure, both in England and in Holland, hence we are obliged to draw our supplies from its native country, Japan, from whence large quantities of many other subjects are received.

From Japan are sent, besides *Lilium auratum* just mentioned and its varieties, huge quantities of *L. speciosum* and *L. longiflorum*, and in a lesser degree *L. tigrinum*, *L. Batemaonie*, *L. elegans* in variety, *L. Alexandrae*, and others, as well as Tree Peonies, all grafted on a stock most prolific of suckers: Fern Balls made up of the creeping rhizomes of *Davallia bullata*; dwarf trees of sorts just now much in vogue; the various forms of *Acer palmatum*; and *Iris Kämpferi*, or rather of this last great numbers used to be sent till a couple of years ago, since when, owing probably to the poor prices realised when sold by auction, very few have made their appearance. Holland, at one time regarded as the sole bulb-producing country, still sends vast numbers to England, though the prospects of our growing many of them in years to come is certainly hopeful. From Holland we receive many *Liliums* (not *auratum*), *Hyacinths*, *Tulips*, *Narcissi*, *Crocus*, *Gladioli*, and a host of other bulbs, shrubs grown especially for forcing purposes, clumps of *Lily of the Valley*, *Dielytras*, *Spireas*, and so on. Belgium contributes vast numbers of Indian Azaleas, hardy flowering shrubs, particularly hardy Azaleas, sundry bulbs, and Palms for decorative purposes. Germany sends *Lily of the Valley* eyes for early flowering, miscellaneous plants in general, particularly large quantities of small trees and shrubs, and above all the bulk of many kinds of seeds, for seed growing is an important industry there.

France also adds to the list, for it supplies great numbers of young trees and shrubs, *Gladioli* bulbs, *Freesias* from the southern part of the country, Roman *Hyacinths* from much the same region, as well as from parts of Italy, while the large quantities of *Lilium candidum* which are on the market here in August and September also come from France. The United States of America nearly monopolise the Tuberose business, while they also send a good many *Gladioli* bulbs. Bermuda has for long made a feature of *Lilium Harrisii*, and while many other things have been tried nothing half so valuable from a commercial point of view has cropped up. *Freesias* grown there attain a very large size, but do not flower in a satisfactory manner, but the double yellow *Oxalis*, known as the Bermuda Buttercup, does well. South Africa supplies Tuberoses, *Lilium longiflorum*, apparently an increasing industry, and various bulbs, most of which are collected in a native state, not cultivated. The West Indies often contributes barrels of *Amaryllis equestris* and *Pancratium* bulbs, but as the call for these is so limited the business in them is not likely to develop to any great extent. Brazil sends Caladiums and various Palm seeds, while the huge quantities of Kentia seeds are usually shipped from Australian ports. Smyrna supplies different

bulbs, particularly *Chionodoxas*, *Galanthus Elwesi*, and to a lesser extent other subjects in the same way. From the Black Sea region we occasionally get a large importation of collected bulbs of *Lilium szovitzianum*, but these are apparently much scarcer than they were a few years ago. This by no means aims at being a complete list of the different subjects that we obtain from over the seas, but rather to call attention to the fact that most parts of the world contribute thereto, even when Orchids, which are drawn from many sources, are omitted. We learn the gratifying fact that bulb growing in this country is greatly on the increase, and hope it will gradually develop into an important British industry.

H. P.

## ENGLISH BULB GROWING.

[To THE EDITOR OF "THE GARDEN."]

SIR.—When at Aldenham recently I had an opportunity of seeing examples of English-raised *Hyacinths*, and certainly the specimens bear out all that is said on page 189 of THE GARDEN as to the future of home-grown bulbs. Never have I seen bulbs of such weight for the size as those shown me by Mr. Beckett, and as firmness and individual weight of each bulb are most important in the production of quality in *Hyacinth* blooms, there seems no reason why in a few years other growers should not take up the raising of home-grown bulbs. It is interesting to see the growth from the start of the tiny bullet to the after expansion into full flowering examples, and is an illustration of what may still further be done in developing this industry, providing suitable soil is at command. The bulbs in question were raised at Terrington St. Clement, in Norfolk, by Mr. W. J. Balderson, a former employee at Aldenham, but now a successful cultivator of English-grown bulbs.

E. MOLYNEUX.

## SEASIDE HORTICULTURE.

[To THE EDITOR OF "THE GARDEN."]

SIR.—Among the many attractions of seaside resorts that have been provided for the pleasure of visitors during recent years there are few that have made so much progress as the laying out of lawns and flower gardens along the promenades facing the sea. Many years have elapsed since my first visit to Boulogne-sur-Mer, and though I have frequently passed through the town, mostly in the small hours of the morning, I have not made a prolonged stay in this old-fashioned watering-place for more than twenty years until last month. The Etablissement des Bains is no longer known by that name, but is now called Le Casino, and its grounds are of course laid out in a manner conducive to the pleasure of such as visit it during the daytime. But the chief improvement to be noticed at Boulogne is unquestionably the excellent way in which the sea front between the Boulevard St. Beurre and the sands has been converted into an attractive promenade. Two long rows of green turf with a wide central gravel path, broken at intervals by side paths, have been formed, and on these are arranged beds of flowers of various shapes and sizes. At regular intervals these beds have between them vases on pedestals filled with flowers, mostly zonal Pelargoniums. An octagonal band stand occupies a position about midway down the promenade, with a gravel walk around it, allowing a free circulation of a large number of visitors who throng to hear the music. The full width of the promenade may be put at about 130 feet, and numerous garden seats are provided for the weary. Round the band stand is a border freely and effectually planted, the back row consisting of single Petunias of various colours trained to sticks about 3 feet high, next is a row of double salmon-coloured zonals, then one of pale pink zonals, and the front row of blue Lobelia.

Quite an imposing effect is obtained by several large raised oval beds, in the middle of which are white Marguerites and foliage plants, surrounded with bright scarlet zonals and an edging of silver-leaved zonals. Here and there variety is obtained by planting some of the beds with Ageratum, others

with Verbenas, Petunias, &c. In one case I noticed a very effective contrast in a bed being planted with a pale pink single zonal, edged with French Marigolds.

The gravel paths between the grass lawns on which these beds are cut are of good width, and the crowd of visitors that thronged the promenade in preference to plodding along the sands show how much such attractions are appreciated, and that such improvements help considerably to popularise those seaside places both at home and abroad where the municipal authorities undertake them.

C. H. P.

## EDITOR'S TABLE.

## ANTIRRHINUMS.

Miss Ethel Case sends flowers of seedling Antirrhinums of pretty colourings. We hope our correspondent will continue to experiment and get good selfs, tall and graceful.

## NEW ASTERS.

Mr. Perry sends from Winchmore Hill three beautiful varieties of perennial Aster, or Michaelmas Daisy, flowers which give warm colouring to the autumn garden. One is named A. Amellus Perry's Favourite. The flower is about as large as a crown piece, and a soft bright purple, with rich orange centre on disc. It is one of the largest we have seen of the Asters, and we welcome its bright and clear colouring. A. Perry's Red is very distinct, entirely unlike the variety just described. It is evidently very free-flowering, and the flowers, though small, are rich in colour—a deep telling amethyst. Another pretty variety sent is Edna Mercia, a small, neat flower, bright yellow in the centre and light amethyst florets. It makes a bright little bush in the garden.

## THE BLACK BRYONY.

A correspondent sends this beautiful native plant, botanically called *Tamus communis*. It has shining green Smilax-like leaves, and a profusion of berries; but many readers will know this wilding, and the illustration will help those who do not recognise it in the hedgerow.

## LOPELIA SYPHILITICA HYBRIDS.

Mr. E. Ladham, the Shirley Nurseries, Shirley, writes: "I thought you might like to know a little about our race of *L. syphilitica* hybrids, flowers of which I enclose. I may say that the flowers are more effective on the plants in the open than when cut. About six years ago Mr. B. Ladham crossed *L. cardinalis* with the hardy *L. syphilitica*, the result being a batch of purple forms intermixed with many apparently of the type. The next cross was from one with rich purplish crimson flowers, itself a hybrid, back on the type (*syphilitica*), the best again being worked on this species. As a result we now have to the third and fourth cross a very mixed lot, a few reverting almost to the types of both parents, whilst others take intermediate and what were probably latent colours. The best of these are now selected permanently and those of sufficient merit are being named. The reason for employing *L. syphilitica* so persistently was, of course, to get the hardy nature of this species, which I am glad to say has been strongly infused into not a few of the hybrids. There are many others besides these herewith sent, but some are cut up for propagating purposes, whilst one or two are so very fine that we cannot spare a bloom, being desirous of getting as much seed as possible from them. They are at best very shy seeders."

[We are much interested in Mr. Ladham's work in this direction. The Lobelia cardinalis is a beautiful garden flower which we should have thought others would have tried to cross to get a

race of flowers of varied and good colouring. The hybrids sent were delightful, a rich assortment of colours, all pure and distinct, and most welcome in the autumn garden. One, a deep blue, was conspicuous among scarlet, pale pink, warm maroon, and other shades. Such hybrids are quite worth a distinct name, and we hope Mr. Ladham will continue his interesting work.]

## SOME GOOD COLCHICUMS.

Colchicums, often called "autumn Crocus," are amongst our most beautiful flowers now in bloom. Strange to say, they are not often seen outside the garden of the amateur, who makes hardy plants a speciality. I have visited large gardens where hardy plants have been grown extensively, but have failed to see a single Colchicum. They will

succeed in almost any position or soil, though they will succeed better if the natural surroundings are somewhat like that of their natural habitat, at least in the matter of soil. I do not think a heavy clayey soil is altogether suitable, but I have seen our native *C. autumnale* happy in a wet, boggy meadow. I have also seen it thriving on its banks. At the present season they look extremely well planted in the grass, which has been kept cut during the summer and now

allowed to grow a few inches. In the mixed hardy border or cosy nooks they also look well, as they also do in broad pockets in the rock garden. There is some uncertainty with many gardeners as to the correct time for planting Colchicums. I have known them taken up immediately after flowering. This must be a mistake. I think the proper season is after they have completed their growth, and just as the foliage is turning yellow. This applies to all the family, whether autumn, winter, or spring species of *Crocus*. If they are taken up and thoroughly harvested and again planted during August I believe they will always do well. I am aware that some good growers do this annually, but I fail to see the need for this except where the soil is bad. In such cases it is undoubtedly necessary. A small collection planted some four years ago is now a mass of flower, and many thousands of tiny seedlings come up each spring. They have become somewhat crowded, and will be lifted at the proper season. These autumn Colchicums are followed by *Croci*, which flower far into winter, and the one astonishing thing about these *Croci* is their hardiness; 12° or 14° of frost will cause the flowers to lay flat on the soil, but immediately the sun shines they are up and fully expanded, and none the worse for the night's ordeal. These *Croci* and Colchicums always look well in the wild garden, especially so in the neighbourhood of Birch trees. When planted in broad patches under and near the silver stems of this beautiful tree they have a fine effect.—T. ARNOLD, *The Gardens, Cirencester House*.

[With this came a small but delightful gathering of Colchicum flowers, and we hope our correspondent's note will draw attention to a beautiful but neglected group of autumn flowers. They must be rightly placed to get the full charm of the clear, soft colouring, not planted in patches in a mixed border.]

## BOOKS.

**Villa Gardens.**\*—There must be thousands of persons in the suburbs of the metropolis that move year by year into new houses with what the builder is pleased to call a garden attached, but which in reality is more often than not a piece of rough ground without form and empty. During the past four years in my neighbourhood alone there must have been no fewer than 2,000 new houses erected, every one of which has a piece of garden ground belonging to it of greater or lesser extent, according to the house. Almost the first consideration that occupies the mind of a newcomer is how to lay out his garden, and twice during the time mentioned I have had to face the problem. Most persons seem to do the work themselves, and with little or no originality as a result. A few whose time is perhaps more valuable and whose purse is longer employ a jobbing gardener, and the result is about the same. The gardens are painfully monotonous, and exhibit a total absence of ingenuity both in the laying out and in the planting. Less than twelve months ago on taking possession of a new house with a piece of ground of unusual size for a suburban villa I thought it wise to consult some of our well-known authors in order to get an idea of what to do for the best. I had heard of Kemp's well known "How to Lay Out a Garden," but being out of print could not come across a second-hand copy. I have several hundred gardening books in my library, but in not one case is there such a thing as a design for laying out a garden great or small. At this juncture a friend lent me Mr. Robinson's "English Flower Garden," in which there are several plans, but these are mostly of large gardens in the country. However, I got from that work a hint which helped me considerably in my difficulty; but it is an expensive book, and in many cases would answer little or no purpose, especially in small gardens of from 50 feet to 100 feet in length, such as the suburban amateur usually gets allotted to him. Quite recently a

THE BLACK BRYONY (SLIGHT REDUCTION).

new book has come under my notice, and I hasten to call attention to it, as it most certainly fills an important gap in garden literature, and if known must prove to be of service to many owners of small gardens, who have to consider the question of laying them out either with or without professional aid. It is entitled "Villa Gardens: How to Plan and How to Plant Them," by W. S. Rogers. This is a nicely printed inexpensive book with illustrations, the most important being a series of nine examples of plans for small gardens, each accompanied by a perspective sketch, which considerably helps the amateur to form an idea of the general effect when completed. In addition to this part, which in my opinion renders the book unique, and which more than justifies the appearance of a new gardening book, there are chapters on what to plant, on garden walks, rock gardens, the summer-house, and various garden accessories, such as seats, arches, &c. To anyone moving into a newly-built house in the suburbs such a book has only to be known to be very highly appreciated.—C. HARMAN PAYNE.

## SOCIETIES.

### NATIONAL CHRYSANTHEMUM SOCIETY.

THIS society's early autumn exhibition of Chrysanthemums was held in the Royal Aquarium on Tuesday, Wednesday, and Thursday last, and a good general display resulted. Dahlias were extensively shown in the non-competitive exhibits. Some excellent bunches of Chrysanthemums were shown, but the large single blooms were not remarkable.

Group of Chrysanthemums and foliaged plants: First, Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham Common, who showed good blooms; the Crotons, Dracenas, Palms, &c., added greatly to its appearance; second, Mr. R. C. Pulling, Monkham's Nurseries, Woodford.

Twenty-four Japanese blooms: First, Mr. J. Brooks, gardener to W. J. Newman, Esq., Totteridge Park, Herts, with very good blooms. Especially well shown were Mrs. T. W. Pickett, L. Monford, Lady Crawshaw, &c.; second, Mr. G. Impey, The Lodge Gardens, Abbot's Road, New Barnet, with fresh blooms; third, Mr. Norman Davis, Framfield, Sussex.

Twelve Japanese blooms: First, Mr. H. Perkins, Greenlands Gardens, Henley-on-Thames. A magnificent bloom of Sir William Acland was included in this exhibit; second, Mr. James Brookes, with good blooms; third, Mr. M. Raymond, North Ockenden Gardens, Romford.

Six Japanese blooms, distinct: First, Mr. R. C. Pulling, Monkham's Nurseries, Woodford, Mrs. Greenfield and Mme. Henry being the best; a good second, Mr. J. Childs, The Priory Gardens, Totteridge; third, Mr. S. Foster, Ten-derden Hall Gardens, Hendon.

Six incurved blooms: There was only one entry, the first prize going to Mr. James Agate, Brockhampton Nurseries, Havant.

Mr. Eric F. Such, Maidenhead, was first for twelve bunches of early-flowering Pompons, showing some good flowers; Mr. T. L. Turk, Southwood House Gardens, Highgate, was second; and Mr. Charles Brown, Langley House Gardens, Abbots Langley, was third.

Two vases of twelve blooms of large flowering varieties: First, Mr. James Brookes with a handsome exhibit; second, Mr. J. Kirkwood, Grass Park House Gardens, Finchley; third, Mr. Norman Davis, Framfield.

Vase of six Japanese blooms, yellow: First, Mr. R. C. Pulling, Monkham's Nurseries, Woodford, with good Mrs. T. W. Pickett; second, Mr. H. Perkins, The Gardens, Greenlands; third, Mr. F. Bush.

Vase of six Japanese blooms, white: First, Mr. J. Impey, The Lodge Gardens, New Barnet, with grand blooms of Mme. G. Henry; second, Mr. R. C. Pulling, Monkham's Nurseries, Woodford; third, Mr. James Brookes, Totteridge Park Gardens, Herts.

Vase of Japanese blooms, other than white or yellow: First, Mr. R. C. Pulling, Monkham's Nurseries, Woodford, with Lily Monford; second, Mr. James Brookes; third, Mr. H. Parr, Trent Park Gardens, New Barnet.

### EARLY-FLOWERING VARIETIES.

Twelve bunches early-flowering varieties: First, Mr. D. B. Crane, Highgate, with some excellent bunches of flowers; second, Mr. E. F. Such, Maidenhead; third, Mr. H. Parr, Trent Park Gardens.

One vase early yellow: First, Mr. D. B. Crane; second, Mr. E. F. Such; third, Mr. A. Taylor, East Finchley.

One vase early-flowering salmon, pink, or rose: First, Mr. F. Bush; second, Mr. A. Taylor; third, Mr. James Brookes.

Vase of early-flowering Pompons: First, Mr. D. B. Crane, Highgate; second, Mr. T. L. Turk, Southwood House Gardens, Highgate; third, Mr. S. Foster, Hendon.

Vase of early white Chrysanthemums: First, Mr. D. B. Crane with a good exhibit; second, Mr. F. Bush, Rose Hill Gardens, Totteridge; third, Mr. F. Gilbert, Kendal House Gardens, Blackheath Park, S.E.

Vase of early crimson Chrysanthemums: First, Mr. Eric F. Such, Maidenhead; second, Mr. D. B. Crane, Highgate; third, Mr. J. Kirkwood, Grass Park Houae Gardens, Finchley.

Vase of early-flowering Chrysanthemums, any other sort: First, Mr. J. Kirkwood; second, Mr. E. F. Such; third, Mr. D. B. Crane.

### DECORATIVE EXHIBITS.

Hand basket of garden flowers: First, Mr. Norman Davis, Framfield, Sussex, with a pretty exhibit; second, Miss Cole, Feltham; third, Mr. M. V. Seale, Sevenoaks.

Hand basket of autumn foliage and berries: First, Miss Cole: a good second, Mr. M. V. Seale, Sevenoaks; third, Mrs. A. Taylor, East Finchley.

Hand basket of Chrysanthemums: First, Mr. M. V. Seale, Sevenoaks; second, Mr. Norman Davis, Framfield; third, Miss Cole, Feltham.

Vase of Chrysanthemums: First, Mr. A. Robertson, Mitford House Gardens, St. John's Wood, with a good exhibit; second, Mr. F. G. Oliver, 97, Tollington Park, N.; third, Mr. T. L. Turk.

### AMATEURS.

Twelve Japanese blooms, distinct: First, Mr. A. Robertson, Mitford House Gardens, St. John's Wood, who showed some very good blooms; second, Mr. J. Childs; third, Mr. M. Rayment.

Six Japanese blooms: First, Mr. A. Robertson, Australie being excellent; second, Mr. W. J. Farrow, Park Hill House Gardens, Clapham; third, Mr. J. Childs.

Twelve Japanese blooms, not less than six varieties: First, Mr. E. Brown, jun., 3, New Alma Road, Southampton, with blooms lacking depth; second, Mr. Thomas Smith, Cobbold Road, Leytonstone; third, Mr. Martin Silsby, Providence, Shanklin.

Six Japanese blooms, distinct: First, Mr. J. Bone, 60, Calverley Grove, Hornsey Rise.

Twelve bunches early-flowering Pompons: First, Mr. T. L. Turk, Southwood House Gardens, Highgate; second, Mr. F. Gilbert, Blackheath Park.

Six bunches early-flowering varieties, distinct: First, Mr. D. B. Crane; second, Mr. F. Bush; third, Mr. C. J. Webber, Muswell Hill.

### AWARDS.

*Gold medals.*—Messrs. Hobbes, Limited, II. J. Jones, Hugh Low and Co., H. Berwick, Henry Cannell and Sons, and W. J. Godfrey.

*Silver-gilt medals.*—Messrs. W. Cutbush and Son, S. Spooner and Sons, Colwill, R. Forster, and E. F. Such.

*Silver medals.*—Messrs. H. Deverill, John Peed and Sons, and Shawyer.

*First-class certificates.*—Mr. Perkins, Greenlands, for Mary Perkins (Japanese); and Mr. Shawyer, Crawford, for Black Prince and Nellie Blake (Japanese).

### NON-COMPETITIVE EXHIBITS.

Messrs. Hobbes, Limited, Dereham, had an imposing bank of Dahlias in many excellent varieties. Roses were also included in this exhibit, which was well and effectively arranged.

Mr. H. Berwick, Sidmouth Nurseries, Devon, displayed a table of hardy fruit that was much praised. The fruits, considering the season, were very good.

Messrs. H. Cannell and Sons, Swanley, Kent, showed a group of brilliantly coloured Canaas.

Messrs. Cutbush and Son, Highgate, N., showed a very good lot of Dahlias in Cactus, Pompon, and single varieties, which were arranged with much taste.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, exhibited Chrysanthemums in pots bearing good blooms, bunches of early-flowering sorts, zonal Pelargoniums, &c.

Mr. W. J. Godfrey, Exmouth, Devon, had an excellent miscellaneous exhibit of Chrysanthemum blooms, Carnation Prides of Exmouth, Michaelmas Daisies, &c.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, showed hardy fruit in variety, and also a miscellaneous collection of plants in flower, Begonias, Liliums, &c.

The new early-flowering yellow Chrysanthemum Horace Martin was well shown by Mr. W. E. Wallace, The Nurseries, Eaton Bray, Dunstable.

Mr. J. B. Colville, nurseryman, Sidmouth, Devon, exhibited hardy fruit in variety and of very good quality also.

Messrs. G. Spooner and Sons, Honnslow Nurseries, Middlesex, showed a table of hardy fruit that contained many good dishes of Apples particularly.

Messrs. Peed and Son, West Norwood, S.E., showed a splendid display of tuberous Begonias, all the blooms being picked from the open ground.

Mr. R. Forster, Nunhead Cemetery, S.E., was given a silver-gilt medal for a group of Chrysanthemums.

Mr. H. Deverill, Banbury, showed zonal Pelargoniums and hardy flowers in excellent variety.

The Pattison Patent Horse Boots for use on lawns were shown by Mr. H. Pattison, 55, Killieser Avenue, Streatham Hill, S.W., and commended. These boots are found to be extremely useful.

Mr. G. W. Piper, Uckfield, Sussex, showed blooms of a new Tea-scented Rose Peace, a lovely cream and yellow flower.

"Floral Aid," a device for holding flowers, was shown by Mr. C. J. Wakefield, 55, Hindon Street, S.W.

Mr. H. Deverill, seed grower, Banbury, offered prizes for vegetablea, and much good produce was exhibited.

### ROYAL HORTICULTURAL SOCIETY.

THERE was a splendid exhibition of miscellaneous produce at the Drill Hall on Tuesday last. Hardy herbaceous flowers, Roses, Orchids, fruit, and vegetables were all well represented. No less than three gold medals were awarded, for Roses, fruit, and Potatoes to Mr. Frank Cant, Mr. Fife, Locking Park Gardens, and to Messrs. Dobbie and Co., Rothesay, respectively.

### ORCHID COMMITTEE.

Present: Messrs. Harry J. Veitch (chairman), James O'Brien, de B. Crawshay, H. Ballantine, Frank A. Rehder, E. Hill, H. T. Pitt, G. F. Moore, T. W. Bond, F. W. Ashton, W. Boxall, W. H. Young, H. A. Tracy, H. Little, J. Wilson Potter, and N. F. Bliluey.

H. T. Pitt, Esq., Rosslyn Gardens, Stamford Hill, N. (gardener, Mr. Thurgood), had a pretty group of miscellaneous Orchids, consisting largely of Odontoglossums. There were besides several good forms of these, Cattleya Mrs. J. W. Whiteley, Lelio-Cattleya *Iris* *Rosslyn* var., Cypripedium Thurgoodii, the blue Dendrobium Victoriae Reginae, Cypripedium bellatulum album, &c. Silver-gilt Flora medal.

An excellent group of Odontoglossums was exhibited by W. C. Walker Esq., Percy Lodge, Winchmore Hill, N. (gardener, Mr. J. Cragg). Several very good forms were included, and the plants were most vigorous. One obtained a cultural commendation. Silver Flora medal.

Messrs. James Veitch and Sons, Limited, Chelsea, showed a handsome lot of hybrid orchids, including Lelio-Cattleya *Nysa* var., Bella, Langleyensis, Tyro, Ophir, and callistoglossa; Cattleya Mrs. J. W. Whiteley, C. Chloe, Lelia *Pacifica*, L. splendens, &c. Silver Flora medal.

Messrs. Charlesworth and Co., Heaton, Bradford, Yorks, showed several beautiful orchids, one of which, Sophrolaelia heatonensis, obtained a first-class certificate. Cattleya Iris, C. callistoglossa albens, C. Kubelik (a pretty flower having C. grandiflora as one of the parents), Sophrolaelia Eros and Eximia, and others were noticeable. Silver Banksia medal.

Messrs. William Bull and Sons, King's Road, Chelsea, sent Cypripedium Sybil, a well-coloured hybrid between C. leucanum areneum x *Salicaria*.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, exhibited a small group of Orchids that contained Cattleya *Firefly* (award of merit), C. Harrisoni, C. Grossii, several Oncidiuns, and Cypripedium insigne Balke. Vote of thanks.

Mr. H. A. Tracy, Orchid Nursery, Twickenham, showed Liparis venosa superba.

Sir F. Wigan, Bart., Clare Lawn, East Sheen (gardener, Mr. W. H. Young), showed L.-C. Ira, L.-C. Constance Wigan (a beautiful flower, L. xanthina x C. Rex), and L.-C. gottschalliana var.

De B. Crawshay, Esq., Rosefield, Sevenoaks, showed Odontoglossum Hallie-crispum roseum.

Cypripedium Charlesworthii Westfield var. and C. Charles Caughan majus were sent by F. Wellesley, Esq., Westfield, Woking (gardener, Mr. J. Gilbert).

A cultural commendation was awarded to Mr. James Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury, for a plant of Dendrobium formosum giganteum var.

### CERTIFIED ORCHIDS.

First-class certificates were awarded to *Lelio-Cattleya Mme. Charles Maron*.—A particularly handsome flower, the result of a cross between Cattleya Warscewiczii and Lelia digbyana. The petals and sepals are long, narrow, and spreading, and coloured a clear pretty rose. The large lip, with heavily frilled edge, is most striking; its colour is the same as that of the sepals and petals; below the column and running into the throat is a mass of yellow. Beneath the column the throat is prettily veined with brown. Exhibited by Baron Schroeder, The Dell, Egham (gardener, Mr. H. Ballantyne).

*Sophro-Laelia Heatoniensis*.—This remarkably handsome flower is the result of a cross between Sophronitis grandiflora and Lelia purpurata. The petals are broad and of a rich crimson-red, the narrow sepals being also of the same colour. The lip is long and somewhat tapering, crimson tinged with purple; the throat is prettily lined. Although small, the flower is very attractive, its colour quite glowing. From Messrs. Charlesworth and Co., Heston, Bradford, Yorks.

Awards of merit were given to

*Cattleya Firefly*.—Cattleya howringiana and Lelia dorminiana are given as the parents of this new hybrid. The flowers, which are borne about six together in a terminal raceme, have sepals and petals of a pretty shade of rosy purple, the lip being a dark velvety purple. From Messrs. Hugh Low and Co., Bush Hill Park, Enfield.

*Lelio-Cattleya Iris Rosslyn var.*—A richly coloured flower of very good form. The sepals and petals are of a clear deep lilac, and the lip is a rich velvety purple, having yellow blotches beneath the column. The petals are broad and well formed, the lip receding. From H. T. Pitt, Esq., Stamford Hill Gardens (gardener, Mr. Thurgood).

### FRUIT AND VEGETABLE COMMITTEE.

Present: Messrs. George Bunyard (chairman), Henry Balderson, J. Cheal, G. Woodward, T. W. Bates, S. Mortimer, A. Dean, H. J. Wright, Edwin Beckett, H. Markham, Henry Esling, G. Reynolds, F. L. Lane, James Smith, C. G. A. Nix, H. Somers Rivers, A. H. Pearson, and O. Thomas.

A splendid collection of fruit was exhibited by Lady Wantage, Lockinge Gardens, Wantage (gardener, Mr. W. Fyle). The exhibit was tastefully arranged, richly tinted autumn foliage being used with excellent effect. The Grapes, arranged at the back of the exhibit, were of very good quality, and the dishes of Apples, Pears, Peaches, Nectarines, Plums, Figs, Cherries, &c., which were placed upon raised stands in front, although not large, were also well shown. Particularly good were the Peaches and Nectarines. The Apples, too, were well coloured.

Mr. J. H. Goodacre, Elvaston Castle Gardeos, Derby, was awarded the Hogg Memorial Medal for fruit for a collection of Grapes, Melons, Peaches, Plums, Pears, and Apples. The Grapes were very good. Melons were represented chiefly by the newly certified variety "The Peer." The Peaches were splendid, and the Apples and Pears, evidently orchard-house grown, were good also.

Messrs. E. A. White, Limited, Beltring, Paddock Wood, Kent, showed fruiting branches of various Apples. Messrs. White also showed very good examples of single Apples. Vote of thanks.

Messrs. James Veitch and Sons, Limited, Chelsea, showed a seedling Pear Lord Methuen (Williams' Bon Chrétien x Citrou des Carmes), apparently a very good fruit.

Mr. J. H. Goodacre showed a good seedling late Grape with large tapering berries, much resembling Diamond Jubilee.

# THE GARDEN

No. 1613.—VOL. LXII.]

[OCTOBER 18, 1902

## THE COTTAGE FRUIT GARDEN.

THE following letter from a well-known fruit grower has been sent to us:—

"No aspect of the home life of the industrious labourers and artisans of England impresses visitors to our shores more than the cottage home embowered and wreathed in Roses, Honeysuckle, and Jasmine, and the garden and windows made bright with flowers. But, strange though it may appear, it is nevertheless true that fruit growing has been lamentably neglected in England. I know of nothing more depressing than the average fruit garden of our country industrial population—a few Gooseberry, Raspberry, and Currant bushes, huddled up in some out-of-the-way corner, almost out of sight, often choked with weeds and forgotten till the time comes round that a crop of fruit is expected from them; a crop often generous, and undeserved under such conditions of neglect and indifference.

"What a transformation might be effected in the improved surroundings and the increased comforts of our country cottage homes by the education of our workers in the elementary lessons of hardy fruit growing! Would that each country cottage had attached to it or within a convenient distance of it half an acre of land, half planted as an orchard with standard trees of the most approved varieties of Apples, Plums, and Pears in rows 20 feet apart, and the same distance between each tree. Between each row could be planted bushes of Gooseberries, Currants, and Raspberries, as well as Potatoes and other vegetables, reserving a quarter of an acre next to the house for bushes or pyramid trees of the best Apples, Pears, Plums, Cherries, and Strawberries.

"The vacant wall spaces of all buildings could be covered with choicer fruits, such as Peaches, Nectarines, Apricots, Pears, and Plums. Once such a garden and orchard were planted, in the space of a couple of years many of the trees would be in a condition to yield some fruit with the pleasant and comfortable prospect of a sure and steady increase in value afterwards each year for from ten to twenty years to come. This piece of land would bring in, when the trees were perfectly established, £15 to £20 a year, and a larger sum if the most were made of the land. This solid and tangible advantage would not be the in hand."

only gain, but the rising generation would be taught an industry calculated to fill their leisure life with interest and pleasure, and be also the means probably of weaning them from the too prevalent temptation of migrating into the town, in most cases to their own and the country's disadvantage.

"It should be remembered that once fruit trees are planted they are little expense afterwards. Half their sustenance is derived from the air, rain, and sunshine. This is no fancy picture I have drawn, but one that has been in existence in France for generations. The fruit industry has given to that nation in return one of the most industrious, contented, and well-to-do peasants of any nation. Naturally, it will be asked, how is this to be brought about? I reply, by the same agency more or less that has brought in and fostered a love of flowers in our rural people. I mean the owners of the land, employers of labour, the clergy, and schoolmaster, working in sympathy with their humbler neighbour the workman. It would be easy to form a fruit committee, constituted as above, in every village or district of every county, with the object of finding out ways and means of bringing this about. The initial cost in fencing and planting the land would probably be the greatest difficulty, but this would right itself in the course of a few years by the added value accruing to the land, in which both the owner and tenant should participate.

"Fruit shows could be organised and some of them held in winter, causing healthy rivalry among growers of Apples and Pears. There would be no lack of subjects for the consideration of such a committee. One of the most important and useful points to engage their attention would be the best means of disposing of the produce of the garden in order to secure to the grower fair and remunerative returns in exchange for labour, instead of as now the railway company and the middleman grabbing three parts of it. I saw Apples exposed for sale in a shop window in a poor district of London a few days ago at 2d. per lb. (equal to 10s. a bushel), evidently windfalls. I have often seen better fruit given to pigs. The question is how much the grower obtained for these? Did he receive 1s. per bushel? He would certainly not receive more. Yet they are sold to the poor at this extortionate rate. There is good work to be done in this way. I hope that those interested will wake up and take the matter earnestly in hand."

## EDITOR'S TABLE.

### NEW VARIETIES OF THE CARDINAL LOBELIA.

I should like to call attention to the fact that there is a Lobelia cardinalis being distributed in England under the name of Lord Ardilaun, which is not true. When in England recently I saw an exceedingly poor variety grown under this name in two of the principal places near London. As the raiser of both Firefly and Lord Ardilaun Lobelias, I called the attention of the gardeners to the fact that they had not the latter Lobelia true to name. I have obtained my employer's permission to send the true Lobelia Lord Ardilaun to those two gardeners. I exhibited on September 23 at the Drill Hall meeting, Westminster, good specimens of the above 5 feet 3 inches high, the main stem furnished with fifteen side branches, also Firefly, and a new seedling named St. Anne's. Although I have received many congratulations, and have seen many notices of the exhibit in English, but not gardening papers, I did not see the exhibit even mentioned in any horticultural journal. The principal object in sending the above to the Royal Horticultural Society's meeting was that the public might have an opportunity of seeing those Lobelias in their true form. I am sending specimens of the above for your inspection.—ANDREW CAMPBELL, *The Gardens, St. Anne's, Clontarf, County Dublin.*

[We are very glad of an opportunity of seeing these beautiful Lobelias, and congratulate our correspondent heartily upon his success. Firefly we consider the brightest of its race, and we have planted it largely by waterside, where its brilliant flowers in the autumn are much liked. The varieties sent to us are remarkable in many ways. The stems are over 5 feet high, branch out freely, and the leaves of dark purplish shade, which brings out the richness of the flower colouring. The variety St. Anne's has very warm crimson flowers, those of Lord Ardilaun brighter, and this is the result of a cross between Firefly and Fulgens. We hope Mr. Campbell will continue his good work in raising new varieties. Such varieties of L. cardinalis add greatly to the beauty of the garden in autumn.]

### FLOWERS OF EUCHARIS AMAZONICA.

Mr. J. Glasheen, gardener to A. J. Ashbee, Esq., The Retreat, Cam, Gloucestershire, sends flowers of this beautiful and well-known plant. They were of exceptional size and showed skilful culture. Mr. Glasheen mentions that the flowers sent represent the "third display in thirteen months."

### ZONAL PELARGONIUM FLOWERS.

Mr. B. Thompson, Wollaton, Nottingham, sends flowers of seedling zonal Pelargoniums, which, if the plants are of good habit and in other ways satisfactory, should prove of much use in gardens.

A salmon-rose flower marked No. 1 had very broad petals of clear and distinct colouring; No. 2 is a good rose-carmine, a pretty shade. It is difficult to tell from cut blooms whether these seedlings are any improvement upon the many named kinds in cultivation, but we like to see attempts made to get new races and varieties of flowers.

#### PEAR MICHAELMAS NELIS.

Messrs. Bunyard and Co., The Royal Nurseries, Maidstone, send fruits of this delicious Pear, which was given an award of merit at the meeting of the Fruit Committee of the Royal Horticultural Society on the 7th inst. It is a seedling from Winter Nelis, which Messrs. Bunyard found by chance in a cottage garden. The fruit is of pretty shape, medium size, and of a cool refreshing flavour. It is one of the best flavoured Pears we have tasted, and this is a year when, owing to the absence of sun, all fruits seem simply bags of water. We hope to illustrate this Pear shortly.

#### SINGLE TUBEROUS BEGONIA FLOWERS.

Messrs. Peed and Son, Roupell Park Nurseries, Norwood Road, West Norwood, send a charming gathering of cut Begonia flowers, picked from the open ground on the 14th inst. We were pleased to see so excellent a gathering of outdoor Begonia flowers. They were fresh, large, but not coarse, and of many beautiful shades, some self scarlet, others deep crimson, while salmon and yellow, pink, and other coloured varieties were sent. A delightful strain of flowers.

#### SEEDLING MICHAELMAS DAISY DOROTHY WEAVER.

Mr. T. J. Weaver, Thirlwood, Woodside Park, N., an amateur gardener who occasionally sends most helpful notes to THE GARDEN, sends a seedling Michaelmas Daisy, which is described as evidently "a cross between *A. horizontalis* and some taller variety." It grows about 3 feet high, and forms an effective bush. I should describe it briefly as a white Coombefishacre." A very pretty flower, white with rosy centre, and probably has *A. horizontalis* as one of the parents. We hope Mr. Weaver will go on getting new Asters, and try and break right away from existing forms. We think Asters with larger flowers would be an advantage, somewhat in the way of *A. Amellus bessarabicus*.

## NOTES OF THE WEEK.

#### FORTHCOMING EVENTS.

October 20.—Meetings of National Chrysanthemum Society's Floral and Executive Committees.

October 21.—Royal Horticultural Society, meeting of committees, Drill Hall, Westminster; Horticultural Club, 6 p.m., discussion after dinner on "Fruit Trees in Pots," opened by Mr. T. Alfred Rivers.

October 28.—Croydon Chrysanthemum Show (two days).

October 29.—Kent County Chrysanthemum Show at Lewisham (two days); Highgate Chrysanthemum Show (three days).

October 30.—Penarth Chrysanthemum Show.

October 31.—Finchley and Leyton Chrysanthemum Shows (each two days).

November 4.—National Chrysanthemum Society's Exhibition, Royal Aquarium (three days); Royal Horticultural Society's committee meet: Southampton and West of England Chrysanthemum Shows (each two days).

**Royal Horticultural Society.**—The next fruit and flower show of this society will be held on Tuesday next, the 21st inst., in the Drill Hall, Buckingham Gate, Westminster, 1-4 p.m. A lecture on "Hardy Summer and Autumn-flowering Bulbs" will be given by Mr. P. Rudolph Barr, F.R.H.S. At this meeting the president of the society will confer the Victoria Medal of Honour on Mr. John T. Bennett-Poë, M.A., Mr. Henry Cannell, and Mr. George Massee, F.L.S., at three o'clock. At a general meeting held on

Tuesday, the 7th inst., forty new Fellows were elected, making a total of 975 elected since the beginning of the present year.

#### Cactus Dahlias for the garden.

I was extremely pleased with the able editorial article on the 4th inst. deprecating the present fashion in Cactus Dahlias, which, in its craze for spidery, twisted-petalled forms, has ousted many most excellent varieties invaluable for the decoration of the autumn garden. I was also glad to read "A. D.'s" timely note (page 226) on the necessity of making the ornamental properties as a garden plant the first consideration with Cactus Dahlias. As he truly says, numbers of varieties that take high honours on the show board are absolutely useless for the garden, but the luckless amateur who visits a Dahlia show with the intention of taking notes of the pick of the flowers with a view to ordering a selection is entirely in the dark as to their merits as garden plants, and, ten chances to one, orders varieties that are practically valueless as decorative subjects. Nursery catalogues very naturally ignore the subject, and, as far as I know, no list of the best varieties for giving colour to the garden has appeared for some time in these columns. It would, I think, be a great help to amateurs if some authority well versed in Cactus Dahlias would give them the names of some twelve or twenty of the most ornamental for garden work, as with such a list at hand no disappointment need arise in making a selection.—S. W. FITZHERBERT.

#### Carpeting plants for bulbs.

In Mr. W. H. Divers' article upon the above subject (page 191) several plants are recommended for this purpose, amongst which are named *Aubrieta*, *Arabis*, *Daisy*, *Myosotis*, *Polyanthus*, *Saxifraga*, *Viola*, and others. Admirable as are these for the stronger-growing bulbs that possess comparatively long flower-stalks, such as *Tulips* and *Hyacinths*, they are not so suitable for surfacing ground in which dwarf-growing bulbs are planted as subjects whose foliage does not rise more than an inch or so above the soil. For *Crocus* species and other autumn-flowering species, *Scilla bifolia* and *S. sibirica*, *Chionodoxa*, *Tecophylea cyanocrocus*, *Zephyranthes*, and *Colchicum*, *Ionopsisidium aculea* proves an excellent surfacing plant. A packet of seed scattered over the ground containing the bulbs is soon followed by seedlings, which, after flowering, speedily reproduce themselves by self-sown seeds. A space in the border about 3 feet square, planted with *Chionodoxa gigantea*, was sown in the spring with *Ionopsisidium* seed. This flowered well during the summer, and the soil is now covered with self-sown seedlings that will soon carpet the whole expanse. *Arenaria balearica* is another good dwarf surfacing subject, particularly well suited to planting around *Colchicums*, as it appreciates the shade cast by their large leaves during the summer, and when their foliage has disappeared carpets the ground with a close mat of bright green, starred in the spring with countless tiny white flowers. *Hutchinsia alpina* is also well adapted for the same purpose.—S. W. FITZHERBERT.

#### Cypripedium sandermanum.

The following note has been sent to us by Messrs. Sander and Sons, of St. Albans:—"We have just received the flower of a splendid variety of this rare and remarkable slipper Orchid from Mr. F. W. Moore, curator of the Dublin Botanic Gardens. It is one of the finest varieties we have ever seen, the colours being exceptionally bright, and the flower, while being admirably proportioned, is above the average size. The dorsal sepal has a ground colour of clear yellow, and bears nine broad and distinct stripes of dark chocolate-maroon, in addition to the chocolate edge; the inner surface is glossy, but the outer is covered with short dense hairs. The petals are over 2 feet in length, and broader at the base than is usually the case, curiously twisted, yellow, tinged with green on the basal portions, the edges bearing polished maroon warts and hairs, while at their extreme bases, as also on that, the dorsal sepal is a light beetroot-purple blotch. The yellow shade extends for about 6 inches of their length, then passes into light purplish red with darker marks.

The pouch is carried at nearly a right angle to the upper sepals, the toe of the slipper being a curious shade of olive-brown, softening into yellow on the under parts and side lobes. There are a few light purplish spots on the interior. The lower sepals strongly resemble the upper in shape, &c., but are more compressed and not nearly so bright in colour. The peculiar staminode is typical of this group, which includes *Stonei* and *rothschildianum*. The ovary is soft yellow, and at the base is a large brown-purple bract, striped on the inner surface with twelve narrow lines of a brighter colour.

**New flowering shrubs.**—We are indebted to MM. Lemoine et fils of Nancy for so many beautiful hardy flowering shrubs of hybrid origin, particularly among the *Deutzias*, *Lilacs*, and *Philadelphuses*, that one looks forward as the seasons come round for their catalogue of new plants of this class. In the autumn list just published the most striking feature, judging by the description and accompanying coloured plate, is *Philadelphus purpureo auratus*, which is said to be a seedling from the variety *Fantaisie*, in the production of which (*Fantaisie*) P. Coulteri has played a part. The illustration depicts a flower suggestive of *P. Lemoinei*, but somewhat larger, and while the larger portions of the petals are pure white the base of each is of a rosy purple tint, which would be as stated in the catalogue visible at some distance. It should prove to be a thoroughly good hybrid shrub, that will in time become as popular as the universally grown *P. Lemoinei*. Two new *Deutzias* are also announced, viz., *D. Lemoinei Avalanche* and *D. Lemoinei Boule Rose*, the last-named deriving its tint expressed by the varietal name from *Dentzia discolor purpurascens*, which was introduced from Yunnan about ten years ago. These two new forms of *Dentzia* should become as great favourites as several of the others from the same source that have preceded them, despite the fact that some of them resemble each other pretty closely. Double-flowered *Lilacs* receive an addition of three more varieties, *Jeanne d'Arc*, *Paul Hariot*, and *Vivian Morel*, but as the catalogue already contains thirty-seven varieties from the same raisers it is difficult to see where the points of difference can come in. A most interesting hybrid is announced under the name of *Exochorda Alberti macrantha*, between the species just named and *E. grandiflora*, this last being the pollen parent. It is described as having the habit of *E. Alberti* with the floriferousness of *E. grandiflora*, a description borne out by the woodcut that accompanies it. Two new *Weigelas*—*Dame Blanche*, ivory white, with a yellow throat; and *Perle*, cream, edged with rose—will doubtless prove to be good flowering shrubs. *Berberis japonica flore lutea* is said to be a form of *B. japonica* with chrome-yellow flowers, but whether the Barberry thus indicated is that generally known as *B. japonica*, which at Kew is considered synonymous with *B. nepalensis*, is at least open to conjecture.—H. P.

**Peach Late Devonian.**—Few late Peaches this season have been better than the above, either with regard to cropping, size, or flavour, and the latter is such an important point that any new fruit is worth special notice on that account alone. A few seasons ago this new Peach was placed before the Fruit Committee of the Royal Horticultural Society, and received an award, which it well merited. Messrs. Veitch of Exeter have cause to be proud of this splendid addition to the late Peaches. The fruits are very handsome, and so far with us since the trees were three years old they have always fruited. This season is the best on record, and not only is the crop large, but equally good and ripe on a west wall about September 20, on a south one, rather earlier. Of course in the north the fruits would be later. I have referred to its size and appearance. There are much larger fruits, but Late Devonian is large enough for all purposes, and is beautifully coloured. My experience of very large late Peaches is that they lack flavour. The fruits are a dark crimson on the sunny side, flesh very rich and melting, and the tree a vigorous grower, free from mildew, and, given good culture, a most profitable variety for the season named.—G. WYTHES.

**Rose Alister Stella Gray.**—I have grown this beautiful Noisette Rose for some years and find it one of the most useful of its class. Planted against a low wall facing west it does admirably, and if allowed to grow in its own way it will flower abundantly. It is beautiful in the bud. The flowers are a pale and rather dull yellow colour, and borne in clusters. Where room can be found for two or three plants handfuls of buds may be gathered daily for several months in the year.—T. B. FIELD, Ashwellthorpe Hall Gardens, Norwich.

**Crinum augustum.**—This handsome species is at present flowering in the Palm house at Kew. It is a very desirable plant, both from a foliage and flowering point of view, and as it is of no more trouble to grow than the majority of stove plants it is very suitable to include in a collection of them. It has been in cultivation for a considerable time, having been introduced from Mauritius and the Seychelles about 1818. The leaves are from 4 feet to 5 feet long, 6 inches wide, and channelled. The flower-scape is from 2 feet to 3 feet high, and terminated with a large umbel of blossoms. The scape is sturdy and green, heavily stained with purple. From

**Exogonium Purga.**—This pretty flowering climber, alluded to on page 240, is, apart from the beauty of its flowers, of considerable economic interest, as from its tuberous roots the jalap of commerce is prepared, at least it was the first to be so used, but now I believe the drug is also obtained from other members of the Convolvulaceae family. This Exogonium was, according to the "Dictionary of Gardening," introduced from Mexico in 1838, and in the warmer parts of the country it will, with a little protection, stand the winter out of doors, flowering as stated till cut by the frost. It is in every way a Convolvulus-like plant, with flowers nearly the size of the large-flowered native Bindweed (*Convolvulus sepium*), and violet-purple in tint. With the changes continually taking place in the nomenclature of plants, it is now included in the genus *Ipomea*, the specific name of *Purga* remaining the same.—T.

**Amaryllis Autumn Beauty.**—Nearly all the original species and garden varieties of Amaryllis or Hippeastrum flower during the early months of the year, but to this there are a few exceptions, one of them being *Amaryllis reticulata*, which was introduced from Brazil as long ago as 1677, this being one of the earliest exotic bulbs to

have the characteristic pale band of *A. reticulata*. These hybrids possess the great advantage of blooming more freely than the typical *A. reticulata*, and they serve to extend the flowering season of this beautiful class of plants, for scarcely are they over when the brick red *A. anlica* unfolds its curiously shaped blossoms.—H. P.

**Passiflora edulis.**—I enclose a photograph of *Passiflora edulis* for THE GARDEN. There were six plants, which were planted four years ago on the back wall of a late viney, and when the photograph was taken in June last there were over 800 fruits. It is very much prized here for jam as well as for dessert.—HENRY WORTH (gardener to R. M. Graves, Esq.), Wern, Portmadoc.

**Is Rose Mme. Jules Grolez scentless?**—In THE GARDEN of October 4 (page 232) I read an account of a Hybrid Tea Rose (Mme. Jules Grolez) by Mr. Arthur R. Goodwin, who winds up what appears to be a well-merited encomium on a good Rose with the remark: "It has, alas! a fault—it is scentless." The same gentleman appears to have forwarded a boxful of this Rose to the Editor of this paper, who in his comments (page 240) says: "The scent is powerful and delicious." We seem to have got a little "mixed" here, a state of things for which, perhaps, the north-east wind may be in a measure responsible.—J. C. L.

I must confess that I was rather surprised to read the editorial remarks describing the fragrance of this fine Rose as being "powerful and delicious." This has been far from my experience with it this summer, while last year I only had one plant of it, and did not take particular note as regards its fragrance. I can only suppose that the blooms which I sent to the Editor were improved in this respect by being confined in a box for fifteen hours. On the 8th inst. I submitted some freshly-cut blooms of this Rose to some of the members of our local horticultural society, and they quite agreed with me as to the absence of scent. On the same day I gathered blooms of *La France*, *Augustine Guinoisseau*, *Johanna Sebus*, and *Mme. Abel Chatenay*, all most deliciously scented. Why should not the east wind—as suggested by "J. C. L."—have affected these varieties as regards their fragrance? While writing this note I have before me two blooms of *Mme. Julcs Grolez* and one of the lovely *Johanna Sebus*. This latter is deliciously scented, but the former still refuses to impart any scent whatever. If, therefore, we describe the fragrance of *Mme. Jules Grolez* as being "powerful and delicious," what adjectives are we to use in describing the fragrance of such kinds as *La France*, *Johanna Sebus*, &c.? If it is due to the abnormal season that this Rose has proved scentless with me, I shall only be too glad to hear of it. In that case it will, indeed, be difficult to find any fault with this variety, and I am very pleased to see that in Messrs. Paul and Son's (Cheshunt) new catalogue it is described as being "the finest rose-pink bedding Rose we have."—ARTHUR R. GOODWIN, WORCESTERSHIRE.

The flowers sent were undoubtedly fragrant. When asked to judge a Rose we always find out whether it possesses fragrance or not, as a scentless Rose is, we consider, without a precious attribute of the flower. Perhaps, as our correspondent says, fifteen hours in a box may have had something to do with the matter.—ED.

**Lilium speciosum.**—The dull cold weather that we have experienced during the last summer has left its mark on this Lily, as in many places the flowers are so backward that in the open ground there is but little chance of many of them expanding properly. In the greenhouse it is, however, invaluable, serving as it does to bridge over the time between the summer-flowering subjects and the Chrysanthemums, for its flowers are then very welcome. Established plants, whether in pots or in the open ground, are earlier in flowering than freshly-imported bulbs. If these latter are laid in some cocoanut refuse out of doors as soon as they are received, mostly in December, January, or February, they will,

THE EDIBLE PASSION-FLOWER (*PASSIFLORA EDULIS*) IN THE GARDENS, WERN, PORTMADOC, NORTH WALES. (The trees were planted four years ago.)

twelve to twenty flowers are borne in the umbel. These have slender tubes 5 inches long and deep red in colour. The free portions of the segment are of a rich reddish purple outside and paler within; the stamens have reddish purple filaments and golden anthers. At Kew it is grown in rich loam, and enjoys the moist, warm atmosphere of the Palm house.—W. D.

**Pancratium illyricum.**—I notice that in Mr. G. B. Mallett's table of bulbous plants for naturalising in grass (page 196) *Pancratium maritimum* is included, while the subject of this note is omitted. I should consider both of these to be entirely unsuited for growing in grass, and imagine that in recommending *P. maritimum* for such a site the writer did not draw on his personal experience. As a matter of fact *P. illyricum* is a far more satisfactory plant than *P. maritimum*. I grow the former myself, and have met with it in flower in other gardens, but although *P. maritimum* lives it never or rarely blooms according to the testimony I have received in gardens in the south-west where it is grown. Sandy soil at the foot of a south wall has been found most conducive to success in the case of *P. illyricum*, and from the nature of its habitat the same conditions should be best suited to the successful culture of *P. maritimum*.—S. W. FITZHERBERT, South Devon.

be cultivated here. It has never proved very amenable to cultivation, being a shy flowerer, but when the blossoms are borne they are always much appreciated, being produced during the autumn months. The ground colour of the flower is ivory white or pale blush, overspread with reddish reticulations. Apart from the flowers the whitish stripe down the centre of each leaf forms also a distinguishing feature. Several hybrids between *A. reticulata* and other forms have at different times been raised, notably about twenty or thirty years ago. Mr. O'Brien, when with Messrs. Henderson, of the Pine-apple Nursery, Maida Vale, raised *A. O'Brienii* and several other kinds; while one raised by Mr. B. S. Williams, and named *Mrs. Garfield*, was for a time at least thought highly of. These reminiscences were suggested by the sight of a plant of Autumn Beauty, another variety of this class, in full flower, and very attractive it was, particularly when one bears in mind that the month of October had set in. The variety Autumn Beauty was raised by Messrs. Veitch at Chelsea, and formed one of the novelties distributed by that firm in 1882. It was described as a beautiful and distinct hybrid, raised between an unnamed seedling and *A. reticulata*. The flowers are of medium size and good form, delicate pale rose, reticulated with bright rosy pink. The leaves

with a mat or two thrown over them in the event of very severe frost, keep well till ready for potting. This should be done in March or April, when at least in the southern portion of the country they can be stood out of doors. If left there during the summer the blossoms expand at a time when they are as a rule more valuable for indoor decoration than if they were brought on earlier under glass. Throughout the summer they should be stood on a bed of coal ashes or some other good firm bottom, and if the pots are plunged in cocoanut refuse or some similar material the labour of watering will be greatly minimised. During the growing season an occasional dose of liquid manure will be of service. Aphides are, in the case of this Lily out of doors, rarely or never troublesome.—H. P.

**Erythrina umbrosa.**—Though Erythrina umbrosa, as mentioned on page 227, does not occur in either Nicholson's or Johnson's horticultural dictionaries nor in the "Kew Hand List," either as a recognised species or as a synonym, it is to be found in such old works of reference as Loudon's "Hortus Britannicus" of 1830 and the first edition of Paxton's "Botanical Dictionary." According to these publications it is a native of Caraccas, and was introduced in 1817. The authority for the name of umbrosa is Humboldt and Bonpland, while according to both these works Erythrina arborea of gardens is synonymous with it. I fail, however, to find this latter name mentioned anywhere else.—T.

**Hampstead Heath Protection Society.**—The hon. secretaries, Mr. H. F. Pooley and Miss Emily Field, write: "Will you allow us to call the attention of your readers to the fact that the Charing Cross, Euston, and Hampstead Railway Bill, which asks for powers to tunnel under the centre of Hampstead Heath, is now awaiting its third reading in the House of Commons. We consider that the construction of a railway under the Heath will create a very bad precedent, and we fear that notwithstanding any protective clauses that might be inserted in the Bill, the picturesqueness of the Heath will be seriously injured before many years have passed. We call on everyone of your readers who loves the Heath to write to their Member of Parliament now, asking him not to agree to the route under Hampstead Heath, which route is, to put it at the lowest, absolutely unnecessary. If the present opportunity is taken the safety of the Heath will be secured, but if it is lost we fear that the victory of the commercial speculator, in this instance, will be followed by similar or worse attempts in the future, with fatal results to Hampstead Heath."

## KEW NOTES.

### INTERESTING PLANTS IN FLOWER.

#### Temperate House.

ACACIA LINEATA, A. linifolia, Berlandiera tomentosa, and Tricyrtis hirta.

#### Palm House.

Crinum augustum.

#### Orchid Houses.

Acineta Barkeri, Catasetum christyanum, Cattleya Acandiae, C. marseillensis, Dendrobium Phalaenopsis, Epidendrum Armstrongii, E. raffinerum, Eulophia pulchra, Houlletia brocklehurstiana, Ionopsis paniculata, Laelia-Cattleya Amelia, L.-C. callistoglossa, Miltonia candida, M. Clowesii, M. spectabilis var. moreliana, Mormodes Buccinator, Neobenthamia gracilis, Oncidium crispum, O. Forbesii, O. incurvum, O. varicosum, Polystachys rufinula, and Vanda kimbballiana.

#### T Range.

Amazonia calycina, Aphelandra chamissoniana, Brunfelsia americana, Gloriosa superba, Hippocratea aulicum, Hymenocallis ovata, Ipomoea rubrocerulea, Nerine (various species and varieties), Nothoscordum striatum, Oxalis rusciformis, Plumbago rosea, and Thunbergia grandiflora.

#### Greenhouse.

Acacia platyptera, Angelonia salicariæfolia,

Begonia glaucophylla, B. weltoniensis, Cuphea micropetala, Datura huberiana var. alba plena, Hidalgoa Wercklei, Justicia magnifica var. phlippiana, Lilium sulphureum, Peristrophe speciosa, Plumbago capensis, Primula Forbesii, P. obconica, P. sinensis, Salvia aurea, S. splendens, and Statice macroptera.

#### Aroid House.

Anthurium coriaceum, A. nymphafolium, and Spathiphyllum longirostre.

#### Rock Garden and Herbaceous Borders.

Aconitum Fischeri, Amaryllis Belladonna, Aster in variety, Chrysanthemum uliginosum, Colchicums in variety, Cytisus Henfeli, Kniphofia Nelsoni, Linaria alpina, Polygala chamaebuxus var. rosea, Tricyrtis pilosa, and Zephyranthes candida.

## THE BEST APPLES AND PEARS.

So great is the interest now taken in fruit growing in England, both for private use and for market, that a select list of the best sorts to grow in moderate sized gardens and orchards, arranged in the order of ripening, may be useful to many readers of THE GARDEN at this season of the year. The lists of sorts given in nurserymen's catalogues, though compiled as a rule with the greatest care, are necessarily so lengthy that the list is apt to bewilder the inexperienced, often making a suitable selection of varieties a difficult and irksome task.

### DESSERT APPLES.

#### JULY AND AUGUST.

Early Harvest, Duchess of Oldenburgh, Irish Peach, Mr. Gladstone, Devonshire Quarrenden, and Juneating. It is advisable not to plant too many early Apple trees, as the fruits only remain in good condition for dessert for a short time, and are best eaten a few days after gathering. One tree of a sort is usually enough in a moderate sized garden.

#### SEPTEMBER AND OCTOBER.

Langley Pippin, Worcester Pearmain, Cornish Aromatic, American Mother, Margil, James Grieve, and Lady Sudley. Worcester Pearmain has a reputation of being the best September dessert Apple we have, whether for the home or for market. It is of medium size, sweet flavour, good regular cropper, and on account of its intensely red cheeks, and high and beautiful colour, it is one of the best early dessert Apples to grow for market, commanding as it does a considerably higher price than any other. James Grieve is a variety recently introduced from Scotland, and has come to stay. It may well be termed an early Cox's Orange, one of the best dessert Apples for October.

#### NOVEMBER AND DECEMBER.

Cox's Orange Pippin, Ribston Pippin, King of the Pippins, King of Tomkin's County, Scarlet Nonpareil, Braddick's Nonpareil, Allington Pippin, and Adam's Pearmain.

From November to Christmas, and indeed to the end of January if carefully preserved, Cox's Orange Pippin is of all others the best dessert Apple. Ribston is slightly earlier, and, as is well known, of splendid quality; but the tree does not grow freely in every soil and district, and is always more or less inclined to canker, so that a limited number of trees of this fine variety are now planted. Allington Pippin is a comparatively new variety of great promise. It is of handsome appearance, crops heavily, and is one of those sorts that gives a good return on young trees the first few years after planting.

#### JANUARY.

Many of the November and December Apples will be in good condition well into February, and to continue the supply to the end of March the following varieties should be included:—Northern Spy, Lemon Pippin, Mannington Pearmain, and Wyken Pippin.

#### APRIL, MAY, AND JUNE.

The latest of all dessert Apples are the following, which will continue to give a supply of good

dessert fruit until the end of May and well into June:—Brownlee's Russet, Allen's Everlasting, Lord Burghley, and Sturmer Pippin.

### COOKING APPLES.

#### AUGUST AND SEPTEMBER.

Domino, Keswick Codlin, Frogmore Prolific, and Stirling Castle.

#### OCTOBER AND NOVEMBER.

Grenadier, Ecklinville Seedling, Beauty of Kent, Cellini, Stone's Seedling, and Warner's King.

#### DECEMBER AND JANUARY.

Betty Geeson, Blenheim Orange, Lane's Prince Albert, Baumann's Red Reinette, and Winter Hawthornden. The above will remain in good condition till the end of February, and for a supply after that to the middle or end of June the following are the best varieties to depend upon.

#### MARCH, APRIL, MAY, AND JUNE.

Alfriston, Royal Late Cooking, Bramley's Seedling, Barnack Beauty, Newton Wonder, Chelmsford Wonder, Wellington, New Northern Greening, Norfolk Beaufin, Striped Beaufin, and Annie Elizabeth. Wellington, as is well known, is one of the best approved varieties for cooking we have. Unfortunately, the tree is not an over good grower, and its cropping qualities are not very reliable. A variety more to be relied on as a consistent cropper, and equal to the Wellington in quality and far superior to it in size and handsome appearance, is Newton Wonder. It is a cross between Wellington and Blenheim Orange, and in my opinion is one of the most valuable Apples introduced for many years, and as it becomes better known it is sure to become a popular standard variety, especially for market. Its large size, attractive colouring, and late-keeping qualities invest it with a value which few, if any, other cooking Apples possess. For planting in gardens as bushes or otherwise the trees should be worked on the English Paradise stock and for orchard planting on the Crab stock.

### PEARS.

Of these I will confine myself to those varieties which can be successfully grown in the south and warmer parts of England in the open quarters of the garden and the orchard. Those having walls to cover should reserve them for Peaches, Nectarines, Apricots, and the best varieties of Plums. In more northern and colder climates, of course, the service of the warm wall must be utilised for the successful growth of many of our best Pears.

#### JULY AND AUGUST.

Doyenné d'Eté, Citron des Carmes, Beurré Giffard, Jargonne, and Williams' Bon Chrétien. With respect to early Pears as to the number of trees to be planted, the same remarks apply as to early Apples.

#### SEPTEMBER AND OCTOBER.

Fondante d'Automne, Souv. du Congrès, Beurré Mortillet, Triomphe de Vienne, Marguerite Marillat, Beurré Hardy, Mme. Treyve, Louise Bonne de Jersey, Marie Louise, Conseiller de la Cour, Compte de Lany, and Seckle.

#### NOVEMBER AND DECEMBER.

Doyenné du Comice, Glou Morceau, Thompson's, Van Mons, Léon Leclerc, Beurré Bosc, Durondeau, Pitmaston Duchess, Emile d'Heyst, Passe Colmar, and La France.

#### NOVEMBER AND DECEMBER.

Josephine de Malines, Marie Benoist, Nouvelle Fulvie, Beurré Sterckmans, Passe Crassane, Knight's Monarch, Winter Nelis, Le Lectier, and Forelle.

#### MARCH TO MAY.

Doyenné d'Alençon, Easter Beurré, Olivier des Serres, Beurré de Jonghe, and Marie Benoist; and for the latest of all Beurré Rance and Duchesse de Bordeaux.

#### BEST STEWING PEARS.

General Todtleben, Grosse Calebasse, Vicar of Winkfield, Uvedale's St. Germain, Bellissime d'Hiver, and Winter Orange.

## THE BLACKBERRIES AND BRAMBLES.

THERE can be no doubt whatever that the Loganberry is the best of these new fruits, though the newer Mahdi will in time become a great favourite. I consider both these fruits have a great future, as from the short experience I have had with them they appear to me to grow well where the Raspberry fails. No note of the Brambles would be complete without referring to the Wineberry or *Rubus phoenicolascius*. The latter is very prolific and well worth extended cultivation. In addition to the above fruits, the Barberry may well be included, as, though less grown for its fruits, the ordinary *Berberis vulgaris* or scarlet-fruited Barberry is very useful for adding to Raspberry jam or to mix with Apples. Some years ago I well remember the introduction of the American Blackberries, but very few made much headway in this country; they grew freely enough, but did not fruit as well as one could wish. There were exceptions, and I have seen fine fruits here and there of the Lawton, but I never had much success with them myself. The Parsley-leaved or Cut-leaved Bramble is well worth culture, and I will refer to this later on. In addition to its fruit it makes a handsome climber.

Take the Loganberry first. So far I have never seen this fruit fail; indeed, the older the bushes the heavier the crop, if the old fruiting wood is cut out as soon as the crop is cleared and the new wood tied up or supported, as it soon gets injured owing to its weight and size. This year we have had new shoots quite 15 feet long, and when it is borne in mind that the fruit is produced on this wood next season it will be seen what abundance of fruit is given. The Loganberry resembles the Blackberry in growth but the Raspberry in fruit. The latter is finer than the Raspberry and more acid, but should not be despised on that account. It makes a delicious preserve, and is not at all inferior for dessert when fully ripe. There is no doubt whatever of its value for tarts, and as it closely follows the Raspberry it is most useful. It is described as a Raspberry-Blackberry. Of this I am not quite sure, but Messrs. Veitch, who raised The Mahdi, give it the same parentage, the autumn Raspberry Belle de Fonteney and the common Blackberry. The fruit of the Loganberry I think is slightly more acid than The Mahdi, but that may be a question of taste; both are alike in growth, and both are very prolific, and fill a gap between the autumn Raspberries and the summer fruiters.

I grew some on a north wall, but I find the plants are equally at home grown as pillar plants, or, what is better, trained over arches. I have seen it stated that it does well grown in the same way as the Raspberry, but if grown thus it should have ample space. I recently saw a splendid crop of fruit in the northern part of the country. The plant was trained to hurdles 8 feet high. The plants start into growth early, so I would advise autumn or early winter planting, giving a deeply dug soil. Some think that the Loganberry if grown from seed is not reliable, and I am inclined to that opinion, as our plants, in what may be termed light, poor soil, give very fine fruits, and were obtained from the original stock, whereas I have seen much smaller fruits and less vigorous plants from seed. I need not further refer to The Mahdi, as the two are so much alike, but will add a brief note as regards the other fruits named above.

The Wineberry is very different from those described, and is a very free grower. It makes a strong growth, and in this respect much resembles the Raspberry. The fruits are not unlike a Mulberry, and are produced in profusion. They make one of the most delicious preserves known. Unfortunately, birds are very fond of the fruits, and, unless these are protected, they are taken wholesale. The growths are remarkably robust, and the wood is striking owing to its colour; the foliage is elegant. The plant makes a good climber for large spaces, though it does not attain the proportions of the Blackberry. The culture is

very similar to that of the Raspberry, and the plant may be grown on pillars or fences. It should be given an open position, needs much moisture, and I find it is more particular as to soil and situation than the Brambles. Much interest attaches to these plants when grown as pillar plants or supported by old trees or stumps. Grown thus they are very effective and give little trouble. I fear the Wineberry is less profitable than the others named, as, though it bears freely, the fruits are smaller and less freely produced than the Loganberry, and more difficult to gather or to preserve from birds.

I have referred to the Cut-leaved Bramble, a plant well worth culture. Grown for its fruit it is less productive than the Loganberry, but a useful plant to cover old trees and a handsome climber for fences. The foliage in the autumn is very pretty, and the plant bears a larger fruit than the common Blackberry. The Whitewash Bramble, or Black Cap as it is more commonly called, is a very striking plant for shrubby work. This in the autumn appears as though the stems had been whitewashed or covered with lime. For its fruit alone I do not think it very profitable. The Strawberry-Raspberry (*Rubus palmatus*) is a distinct plant, bearing fruits not unlike the *Arbutus*, but they are not valuable. This plant is small and makes a bush. There is a dwarf creeping kind which does best when given partial shade, but they cannot be termed profitable as regards their fruits. The Red Barberry is well known as being valuable for using with other fruits. It is a free grower and very effective for massing in shrubberies, as it fruits freely, and in the autumn the berries are very striking.

G. WYTHES.

## INJURIOUS INSECTS AND DISEASES AFFECTING FRUIT TREES.

IN the culture of fruit, whether in the orchard, open garden, or under glass, the question of injurious insects and diseases is apt to be looked upon with some amount of dismay, but after all these are rarely to be counted upon as permanent factors, and considered rightly they are the direct and perhaps the most efficient means of keeping the fruit grower in a state of mental alertness.

There are three general types of difficulties in fruit growing, which have been classified by Professor Bailey as follows:—

### 1.—Attacks by insects.

(a) The injuries of those insects which eat or chew the part of the plants, and which, therefore, are killed by the application of some poison, such as Paris green. These insects include the whole tribe of caterpillars, worms, and beetles.

(b) Attacks of insects which suck their food, and which are, therefore, destroyed by caustic applications which injure the bodies of the pests. All the tribes of plant lice and scale insects may be placed under this heading, and for these kerosene emulsion, resin washes, and the like are the specifics.

2.—Parasitic fungous diseases, such as the Apple scab, mildew of the Grape, leaf blight of the Plum and Pear, Currant gall, canker, and the like. These diseases are characterised by definite spots, discolorations, or excrescences, which are more or less distributed over the surface of the root, branch, leaf, or fruit. As a rule, the leaves and fruits which are attacked have a tendency to drop from the tree. The general treatment for these diseases is to spray with some fungicidal mixture. The treatment is useful in proportion as it is applied early and thoroughly. After the disease once gets into the tissues of the host plant it is difficult, if not impossible, to kill it. If, however, the fungicide is applied before the parasite gets permanently established there will be less danger of its obtaining a foothold. Even if the fungus has made headway a thorough spraying will check its progress by preventing the development of its external parts.

3.—The physiological and bacterial diseases or those which are termed constitutional troubles. In these cases there are rarely any definite spots,

as in the attacks of parasitic fungi, but the entire leaf, or even the entire plant, or a large part of it, shows a general weakening by disease, as if there were some cutting off of the accustomed source of nourishment. Such diseases are very likely to be seen in the general yellowing and dearth of the foliage; in the dying of the leaf along the main veins and around the edges, showing that the difficulty is one which affects the entire leaf, and not any particular part of it. In general there is a tendency for the foliage in plants so attacked to wither up and hang on the tree for a time. There are no specific treatments for troubles of this sort. The diseased plant or parts must be cut away and burned. All the conditions which seem to favour the development of the disease must be removed. Careful management in matters of sanitation is often much more important than any attempt at specific treatment.

Injurious insects follow swiftly on the heels of disease, and disease is usually further strengthened by the destructive agency of insect pests.

So far as our experience shows the protection of our fruit crops from insect ravage is likely to be an increasing difficulty, consequently on the increasing extent of the areas in which one kind of orchard tree or fruit bush is grown year after year, thus giving every opportunity for the established settlement of the insect feeders on that special crop.

### APPLE.

Under proper treatment the Apple tree is rarely affected by either disease or insect. It is chiefly when injured by mismanagement, starved for want of plant food or too heavily cropped, that trouble ensues. Soil and climate are powerful factors in the production of Apple disease, and also frequently invite the attacks of insects. The chief causes of injury may, therefore, be stated to be over-luxuriance or weakness of growth.

The chief diseases that attack the Apple are canker, mildew, and American blight. The first is caused by bad drainage, the second arises from many and the most opposite causes, such as improper manuring, over-cropping, excess of heat or moisture.

The attack of the woolly Apple aphid, commonly known as American blight, may be taken as an example of orchard infestation which is exceedingly common, and is very injurious by destroying the health of the tree, and yet at the same time is so open to remedy that it may with little expense or trouble be stopped even at the outset. The presence of the Apple bark plant louse or woolly aphid may be easily detected by the cottony growth on the insects, giving the appearance of a white film. When there are many the spot appears as if a knot of cotton wool were sticking to the bough or even hanging loose in pieces several inches in length.

With regard to remedies, soft soap, tar, or, in fact, anything oily, greasy, or sticky that can be well rubbed on, and which by adhering for a time will choke all the aphides that it touches, will be of use.

Other insects that attack the Apple are the green-fly (*Aphis malii*), codlin moth (*Carpocapsa pomonella*), blue-head caterpillar (*Diloba ceruleosuphala*), goat moth (*Cossus ligniperda*), lackey moth (*Bombyx neustria*), lapped moth (*Gastropacha quercifolia*), small ermine moth (*Hypnometa padellus*), Apple saw-fly (*Hoplocampa testudinea*), and Apple blossom weevil (*Anthonomus pomorum*).

Of all these pests probably the codlin moth is most frequent and persistent, because the attack is one of the regular recurring yearly troubles of the fruit grower, and although the maggotty or worm-eaten condition of the young fruit, which we know only too well as causing it to fall in quantities before it is large enough to be of any use may sometimes arise from Apple saw-hy presence or from other infestation, yet for the most part the mischief is due to the larvae of the codlin moth. Other of our orchard fruits are also liable to this infestation, Pears, Plums, Peaches, Quinces, and Apricots are sometimes much injured. Walnuts and Chestnuts also have been found to be infested. As a prevention and remedy

the following plan may be adopted: Wind a hay-band in three coils tightly round the trunk of a tree at a little distance from the ground and apply other hay-bands to the larger branches. These bands should be placed around the tree early in June and kept on till fruit harvest; further, they should be pushed up or down and the worms or chrysalids crushed that were under them every week or two. Also the trunk of the tree should be kept free from rough old bark so as to give the worms no other place of shelter, and, lastly, the ground itself should be kept free from rubbish.

**Cherry and Pear saw-fly (*Selandria atra*).**—The small blackish moist-looking larva of the Cherry and Pear saw-fly, known as slugworms, from their great resemblance to the little slimy slugs feeding on the upper side of the infested leaves, are often not recognised as caterpillars from their very peculiar appearance, from which they take their name. They feed on the leaves of Cherry, Pear, Plum, and sometimes on Peach and Quince, and they do serious mischief by devouring the skin of the upper side of the leaf, so that the remainder appears like a network of veins held together by the skin of the lower side, which is left untouched and turns to a deep brown colour. The destructive work of the caterpillars can be at times very rapid and complete. The attack may be checked by dusting or spraying. The caterpillars, if annoyed by throwing a caustic powder on them, such as quicklime or gas-lime, can throw it off at first by exuding a coating of slime and thus as it were moulting off the obnoxious matter; but they cannot keep on continuing this process, therefore a second application of the powder (soon after the first) takes effect and kills them. If a good time is allowed to elapse between the dressings they will have regained the power to produce the slimy exudation, and the application will do little service. Heavy syringings of the tree with strong soapuds applied by a powerful garden engine are very effective in getting rid of this pest. Also a liberal dressing of lime and soot well mixed together is a capital remedy; in this case a thorough washing down of the foliage on the following day, so as to clear off the adhering coating, is needed to complete the work.

#### CURRENT.

Current aphides or green-fly (*Aphis ribis*) are injurious by crowding beneath the under side of the leafage and by their innumerable punctures and drawing away of the sap give rise to the brightly coloured blistered or humpy growths so often seen on the upper side of the Current leaf, and in bad attacks nearly the whole of the foliage will be distorted and crumpled out of shape and the fruit will be blighted. Where much damage is being caused it is a good plan to break off the leaves and burn them. In dry weather an application of plentiful waterings so as to keep up good growth of the foliage is in itself a great check to aphis increase.

**Current gall-mite (*Phytoptus ribis*).**—The deformed bud growths, which for many years have been a source of great trouble to Black Currant growers, are caused by an exceedingly minute mite, too small to be seen by the naked eye, which propagates in the buds and causes an unnaturally large development of these into spherical green knobs, formed outside of greenish scales or abortive leaves folding over each other, and inside of the various parts which would gradually have developed into leaves, flowers, and fruit, but contorted by the action of the mites into unnatural conditions, and abortive for any useful purpose. These knobs may be found forming during the winter, whilst the healthy buds are still of the natural shape, and in January will have attained to as much as a quarter of an inch in diameter, and containing within them numbers of the mites and some eggs.

**Prevention and Remedy.**—The method which is most frequently tried is breaking of the galled buds and burning them, and though it cannot but be that in this way a great deal of the mite presence is got rid of, which would have otherwise spread infestation, yet the plan is very far from answering as could be wished. Among observations of treatment from which some amount of

good resulted was a dressing of 2lb. sulphur and 3lb. lime, boiled together in three gallons of water, which is further diluted at the rate of two or three pints to a large pail of water, applied with a syringe to the infested bushes.

#### GOOSEBERRY.

The Gooseberry when planted in suitable soil is rendered peculiarly free from disease, but there are several insect pests which are very troublesome. Among others may be mentioned the magpie moth (*Abraxas grossulariata*), dot moth (*Mamaestra persicariae*), Gooseberry and Ivy red spider (*Bryobia praetiosa*), Gooseberry and Currant saw-fly (*Nemetsis Ribesii*), and the Gooseberry and Currant scale (*Leeanium ribis*). The greatest amount of damage is probably done by the magpie moth and the saw-fly caterpillar. The pretty butterfly-like magpie moth is one of the most widely distributed garden leafage infestations. The common garden food plants of the caterpillars are Gooseberry, red and white, and sometimes Black Currant, and the foliage of Apricot and Pear is also attacked.

**Prevention and Remedy.**—The habit of the caterpillars of wintering in spun-together leaves still hanging on the bushes, or sometimes lying amongst any shelter on the ground beneath, is the special habit to be acted on to get rid of the pest. At pruning time the bushes should be carefully gone over to make sure that there are no leaves which may hold a caterpillar. When Currant bushes are trained on walls search is especially requisite. The longer the pruning can be deferred the better. Pruning and dressing under the bushes should not take place until the time for the fall of the leaves is quite past. All the pruning and possibly infested rubbish from beneath the bushes should be collected and burnt. Flowers of sulphur dusted on the leaves when the dew is on, or a liberal application of soot similarly used, are serviceable remedies and safe.

The Gooseberry and Currant saw-fly attack is perhaps one of the most destructive that bush fruit growers have to contend with, on account of its frequent recurrence and the great powers of ruining the leafage of the attacked leaves even by scores of acres. The life history is that the female saw-fly appears about May and lays her eggs beneath the skin of the leaf. The grubs soon hatch and begin feeding on the leaf where they are placed, which they pierce full of holes, and continue to feed on until all the leaf, excepting the mid-rib, is devoured. Thus they continue their work of destruction, moulting from time to time, and hanging on to the leaf with their fore legs, with their tails in the air. After the operation of casting the skin for the last time, they go down with the soil and bury themselves, to turn to the pupal state, from

which the saw-flies come out in three weeks in summer, or in the case of late broods in the following spring. For prevention of attack, excepting what may be borne on the wing by stray saw-flies from elsewhere, the most certain plan is autumn or winter removal of surface soil from under the bushes. A deep hole may be dug in some other place into which the removed soil with whatever may be in it is buried. The soil under the fruit bushes may be replaced by that taken out of the hole with the addition of some manure. Hand picking is recommended, also dressings of sulphur powder when the dew is on the bushes.

J. J. WILLIS.

(To be continued.)

#### SOME VALUABLE PEARS.

DURING the past few years many valuable hardy fruits have been introduced. The new Pears are most interesting, and the variety illustrated, Marguerite Marillat, a valuable September fruit, will, I think, prove most profitable. It will be said that we have too many Pears, but the variety

#### MARGUERITE MARILLAT

does so well in a poor fruit soil, and crops well even in bad seasons, that I think its popularity is assured. With regard to flavour it is not so good as Doyenne du Comice, doubtless the best Pear we have for flavour, but even the last-named variety is not a success in all parts of the country. The variety illustrated

A BASKET OF MARGUERITE MARILLAT.  
(Reduced one-half.)

was introduced from the Continent a few years ago. It is a large, handsome fruit, of sugary aromatic flavour, very handsome in shape, and beautifully coloured. The trees are of an upright, close growth, and well adapted for garden culture, either as a bush or a pyramid. It is a great cropper, but does not keep long, being a September fruit or at its best early in October in late districts. There are other fruits quite as valuable at this season, such as

#### TRIOMPHE DE VIENNE AND BEURRE MORTILLET,

the latter a large, handsome, early October variety. This I have found in some gardens grown under the name of the new variety referred to, but it differs greatly; though a good Pear, it does not crop so well, and is later. It may be asked if these new Pears are not better than older ones. What value do they possess? I think I have explained that there is ample room for them in their season if good. What would certainly be most valuable to fruit growers would be varieties that would keep longer. After Christmas good Pears are very scarce, and at times even the late kinds do not keep so late as catalogued; they do not always finish well in diverse soils. The variety advised above does well on the Quince stock, and we find it one of our best varieties for cordons; this method is a good way to test the merits of any new Pears, as it may soon be grown into a fruiting size and the flavour compared. In hot seasons it is even earlier than I have described. Last year we gathered fruits the last week in August. It is a good plan with these early Pears to take a few fruits from the trees at intervals and place in the fruit room, as by this means a longer supply is maintained. Another very fine fruit is the new

#### LE LECTIER,

a hybrid raised in France, Williams' Bon Chrétien being one of the parents. This is well worth attention, the fruits being large, finely shaped, with rich melting flesh, and of splendid flavour. Fortunately, it is a late Pear, its season being given as January to March. So far I have never been able to keep fruits long after Christmas. This variety with me crops well and grows strongly, so that it needs ample space. Another excellent Pear that has come to the front of late years is

#### PRESIDENT BARABE.

Though it is not so large as the varieties noted above, it is of splendid quality, and in season in midwinter. It is of compact growth, and bears well. This was one of the best flavoured Pears noticed by the Royal Horticultural Society a few seasons ago when prizes were given for flavour. Another promising fruit is

#### ST. EDMUNDS,

a seedling from the celebrated fruit nurseries of Messrs. Rivers, Sawbridgeworth, and though full early to note its cropping qualities, its flavour is first-rate, and the season November. There are others, such as

DR. JULES GUYOT AND BEURRE PERRAN, well worth including in this list. The first-named is an early September fruit, the latter a midwinter variety. Both are good for flavour, and crop and do well in bush form. Dr. Jules Guyot is not unlike a large Williams', and is a compact grower on the Quince stock. In planting Pears for dessert I would never advise those who have space to plant a mere list of varieties, but those kinds in quantity that are known for their flavour and crop. There is no merit in having so many kinds;

indeed, the grower cannot maintain a regular supply, for though many kinds of fruits may be interesting, they are by no means profitable. G. WYTHES.

#### RASPBERRIES IN AUTUMN.

AUTUMN Raspberries when well grown form an important crop in a private garden, and are much appreciated for cooking, besides which they may, if the weather is really fine and warm when they are ripening, provide a welcome change in the dessert, and carry on the season of small fruits to the end of October. It is not uncommon to find a few rows of these double bearers, an unfortunate name by-the-by, as I hope to show, growing with the summer sorts, and from these some late dishes are got; but the greed which requires two crops from them defeats the object for which they are grown, as the first crop, borne on last year's canes, strains their resources and prevents the second crop, borne on canes of the current year's growth, from being anything but an average one. Why it is left for Raspberries to produce two crops while we are content with one of any other fruit is a mystery. The summer crop on the autumn bearers, such as Belle de Fontenay, the best and finest, and the red and yellow Four Seasons, which are both very prolific, is not necessary, as the regular summer bearers should then be providing quite sufficient for the household.

My practice is to cut down the autumn bearers to the ground in February or March, and to thin out the new suckers which appear soon after sufficiently to allow them plenty of room. Any extra strong sucker which may appear well ahead of the rest on the stool should be cut away, as these in a cold season will keep on growing without showing fruits and rob the medium-sized growths. We generally begin picking here about the middle of September, and, as this is a late district, this means that they sometimes overlap the laggard fruits on the summer varieties. Last year our autumn crop was magnificent, and from about 40 yards run of canes we picked one day, about the middle of October, 18lb. of as fine fruit as one could wish to see. This year the promise is even better, though of course much depends on the weather; but every shoot is laden with fruits and blossom in all stages, and picking has been going on for some weeks.

Autumn Raspberries, like the summer varieties, enjoy liberal treatment, and the ground when being prepared should at least be deeply dug, and as the beds should last for many years some good manure from the stock-yard, together with any bones, burnt rubbish, and anything that will tend permanently to enrich the soil should be dug in. October and November are the best months for planting, and the canes should be from suckers that have appeared at some distance from the old stools, as these are most likely to grow away

PEAR MARGUERITE MARILLAT AS A CORDON (SHOWING FRUITFULNESS) IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT CHISWICK.

freely. Each year a good mulching of manure should be given in March or April, and in dry seasons on hot soils it may be necessary to give soakings of water, though in this respect the autumn bearers are more independent than others, as they have no old growth to support.

*Shipley Hall Gardens.*

J. C. TALLACK.

[We noticed the autumn Raspberries recently at Shipley bearing a quantity of clean, wholesome fruit. These late-bearing Raspberries are as important as the summer crop.—ED.]

#### APPLES FOR COLD WET SOILS.

The planting season is now upon us, and with it one of the greatest pleasures of the garden lover—that of choosing new fruit trees. Anyone in the habit of going much to fruit shows must have noticed that it is rarely, if ever, that in a collection of Apples every variety is of the highest excellence as a specimen of that variety, and that there are always some of which one feels one has seen much better specimens before. This is because there is no soil which suits all Apples, however good an Apple soil it may be. Though Apples of a sort may be grown practically anywhere, really satisfactory fruit of most varieties cannot be grown everywhere, and the object of this article is to suggest certain sorts which may be grown in a satisfactory way under the conditions mentioned at the head of the article, and to warn the intending purchaser from courting certain failure.

People go to shows and see the most gloriously

coloured Apples beautifully arranged on dishes; they take down the names of those which most take their fancy, and, without giving any thought to the subject, order the trees from their nurserymen, only to find that some at least of the trees are a failure. Catalogues, too, are often somewhat misleading, as they say everything there is to be said in favour of an Apple, and do not mention that it will not succeed under certain conditions.

First, it will be well to warn the owner of a wet, clayey soil of the most likely pit-falls in planting Apples. There are certain varieties which everyone wants to plant, and two of the most common of these are Cox's Orange Pippin and Ribston Pippin, both rightly considered to be without a rival. Both would be certain failures in our case—the former cankering little less than the latter in many places—needing, as they do, a warm, rich soil. Another is King of the Pippins, rather overrated except at its best. It is very often a failure, as it, too, needs a warm, rich soil, as do also that famous show Apple King of Tompkins' County and that king of cooking Apples The Wellington, or Dumelow's Seedling, the latter of which especially cankers terribly in an unsuitable soil. Mannington's Pearmain, another gem, is scarcely less risky to plant, and the Old Nonpareil, like many of the very old sorts, is much inclined to canker. If a soil is unsuited to a particular variety it does not necessarily canker, as some sorts are not liable to it or very rarely fall a prey to it, but they may refuse to bear or to do so very sparingly, or the fruit may be much undersized. The Apples above mentioned are varieties that everybody would like to grow, as in Plums everybody wants to grow the old Green Gage, with which very few really succeed. It is one of the cases where discretion is the better part of valour.

Having started with this negative advice, let us come to practical matters. And here let it be insisted that whatever is said in this article as to sorts which will or will not do well in cold wet soils when a good sort, and one the intending planter likes is seen flourishing in a neighbour's garden, by all means plant it. Conversely, if a sort you would like to plant is seen to be a failure on a soil just the same as yours, by no means plant it unless you happen to know your neighbour has treated it wrongly.

#### DESSERT APPLES.

We will first deal with dessert Apples. Of these one of the most reliable is Brownlee's Russet, an ugly enough Apple it is true, of medium size, but very sweet and juicy and richly flavoured, and it is in season from February to May. It needs to be left on the tree as late as possible, as it possesses the russet tendency to shrivel, but if picked late and stored in a cool place it is very fine. It is most prolific, and will do well in almost any soil. Lemon Pippin is a good old Apple whose origin is lost in obscurity, but, under the name of the Quince Apple, it must have been grown for several centuries, though it is now rather falling into neglect in competition with the host of newer varieties. It is an excellent bearer, and when well grown is of a good size and rather handsome, being in shape and colour something like a Lemon. It is good for dessert from Christmas till Easter, and for culinary purposes throughout the winter. I have a standard tree growing side by side with a standard Cat's-head, and though the latter is, and has been for twenty years, badly cankered, the Lemon Pippin has not a trace of this disease, or more properly parasitic fungus, while the soil is low lying and near a river. A Queen standard planted near it ten years ago is catching the canker from the Cat's-head already. Court Pendu Plat is a good dessert Apple, of free-bearing habit, in season from February to April; not a pretty Apple by any means, either in colour or shape, but it has the great recommendation for low lying situations, where spring frosts are often so persistent, of being about the last of all Apples to come into bloom, and therefore often escapes a sharp May frost which destroys the bloom of the earlier flowering sorts. Baxter's Pearmain is a very hardy and vigorous grower, and very prolific, of medium size, greenish tinged with red, beautifully crisp and

slightly acid—a recommendation to many—and is in season at Christmas and for some time after. Another Apple in season at Christmas time is the Christmas Pearmain, which was introduced by Messrs. Bunyard in 1895, and seems likely to become a great favourite. It is an enormous cropper and free from canker, is of medium size and very pretty, having a scarlet cheek with russet markings, and is altogether a very desirable addition to the dessert at that season of festivities. Most of the Nonpareils are too delicate for wet soils, but there is one which will grow almost anywhere, and this is the Ross Nonpareil. It is of medium size, of general russety appearance, with a red cheek where it catches the sun. It is of delicious flavour, most prolific, and is good for dessert for pretty well six months—November to April. The above is a selection of dessert Apples all of greater or less excellence, and may all be tried on a cold wet soil with a reasonable hope of success. No early sorts have been given, but if any are wanted the Red Jnneating or Joaneting, sometimes called Margaret, in season in July, and the Harvest Apple, in season in August and early September, generally succeed in any situation. Both are very old-fashioned Apples, seldom met with in orchards of more recent planting, and both are very good to eat direct from the trees. When we come to

#### COOKING APPLES

we have the old Keswick Codlin, a very early variety, being of a culinary size as early as July, though more properly in season in August and September. It is now going out of fashion, being superseded by newer varieties like Lord Grosvenor and Lord Suffield, the latter of which cankers so badly as to be out of the question for a damp soil. Early cooking Apples are not the best to plant, as in August and September anyone who has anything of an orchard has more windfalls than he has use for. A more useful sort is Bismarck, an Apple of recent introduction from the southern hemisphere rapidly rising into popularity. It is a large Apple, of good firm texture, almost equal to Wellington in that respect, and of handsome appearance. It is a very useful Apple during the midwinter months: the tree is a very prolific bearer even in a young state. An equally valuable Apple, though not coming into bearing so early, but a regular cropper when established, is the much advertised Bramley's Seedling, a very large Apple, in season the whole winter and spring. It is a tremendously vigorous grower, and seems likely to make magnificent standards, as it does very large bushes. It promises to be one of the great favourites of the future. A large variety of Apples for cooking is not necessary so long as we get a supply in good condition through the winter, but one more will be given suitable for our purpose, and that is the Winter Queen, or Sussex Duck's-bill, in season during the midwinter months, and fit for dessert if left on the tree late, when it becomes a good colour. It is not well known, being often ignored in some catalogues, but it is one of the best for the soil we are concerned with.

It is surprising how rapid has been the growth of interest in Apple culture, and the orchards of the future will not be occupied by such rubbish as many of them are to-day. It is just as easy to grow a good sort as a bad one if care is exercised in the selection, and, as shown above, there is a number of most excellent sorts so hardy that they will grow in the stiffest and most forbidding-looking clay soil. Generally speaking, when dealing with a wet cold soil, it is more satisfactory to grow bushes than standards, and these should be on the broad-leaved English Paradise stock. As every fruit grower knows, the Crab stock runs down almost perpendicularly into the subsoil, while the Paradise stock ramifies through the surface soil, having much more root fibre than the Crab. Hence a Crab stock running down into the clay either induces canker or rampant growth. Bushes need not necessarily be small garden trees such as are recommended to be planted 6 feet to 9 feet apart, which, though coming into bearing very early, still obviously can never produce fruit by the bushel; but they may be grown in a free manner, forming trees 10 feet

or 12 feet high or more, each stem forming a cordon furnished with fruit spurs from top to bottom. Such a tree may easily produce two or three bushels of fruit in a season, and, being low, there is not nearly so much loss through autumn gales, while it will produce such a crop as mentioned if it has been properly trained, by the time the standard would just be beginning to come into bearing. Growing on the bush system has the further recommendation of enabling the owner to make two pickings of the fruit, those on the sunny side of the bush being ready first, and as Apples on cold soils are always later than those on dry warm soils, it is a great advantage, especially with the later varieties, to be able to leave the Apples on the tree till they are fully matured, even if it is into November. As an instance of what may be done with bushes, the superintendent of the Royal Horticultural Society's Chiswick Gardens states that he has repeatedly picked 28lb. of Apples from a bush the second season after planting.

ALGER PETTS.

## NOTES ON HARDY PLANTS

### CYCLAMEN EUROPÆUM.

**N**EARLY every week in autumn I see mistakes made in the flower notes of gardeners, who wrongly call the hardy autumn Cyclamen *C. europæum*. I know only one hardy autumn Cyclamen, and its right name is *C. neapolitanum* (Tenore). It used to be confused by botanists with *C. europæum* (Linnaeus), but Mr. Baker set the names right more than twenty years ago, and both the "Kew Hand List" and "Index Kewensis" have confirmed the distinction.

*C. neapolitanum* (Tenore), native of Southern Italy and Sicily, begins to flower in ordinary seasons about the last week in August. The leaves, which are large and pointed and marbled, follow in about a fortnight and last into spring. The colour of the flowers varies from crimson to white. It is naturalised in some places in England, and so included in the British Flora, though wrongly named *C. europeum* both by Sowerby and by Bentham. It is of the easiest cultivation, thriving in my garden in Cheshire in any soil or situation, and coming up from self-sown seed, which ripens in a year if spared by birds and mice. I see this species in many rocky shrubberies in North Wales permanently established, though only in private grounds.

*C. europæum* (Linnaeus) is a native of South-eastern France and Switzerland. It has smaller and round, glossy, dark green leaves without variegation, and produced before the flowers, which are shorter in the petals than those of the former species, and come in July, being generally over before those of *C. neapolitanum* begin. In spite of repeated importations from Aix-les-Bains, where it abounds, I have never been able to make it thrive, nor have I ever seen it in English gardens comparable for ornament and vigour with *C. neapolitanum*, though it has one advantage over that species in being very fragrant.

*Llandudno.*

C. WOLLEY-DOD.

### CROCUS SPECIOSUS.

#### A BEAUTIFUL AUTUMN CROCUS.

The Crocuses most generally met with in gardens are the spring-blooming Dutch varieties, which make such a brilliant show in the borders with their golden-yellow, deep purple, pure white, and striped lilac. One cannot but admire their beauty and brightness, but the admiration is tinged with regret that other species flowering in the autumn and winter,

and equally lovely, suffer such unmerited neglect, for few and far between are the gardens in which they are met with. Of the autumn-flowering Crocuses, *C. speciosus*—the subject of the accompanying illustration—is the handsomest, and a large mass makes a charming picture towards the end of September and beginning of October, the petals of purple-blue, delicately veined, being set off by the glowing orange anthers. As the flowers are produced in advance of the leaves, which do not make their appearance until the spring, it adds materially to the effect if the bed is carpeted with some dwarf plant. *Ionopsidium acaule*, sown in the late summer, makes a pretty surfacing, its tiny lavender-white flowers contrasting well with the purple of the Crocus. Mossy Saxifrages, Thymes, Creeping Jenny (*Lysimachia Nummularia*), and other dwarf plants may be used for the same purpose. On grassy banks *Crocus speciosus* is very beautiful, the green of the grass forming an excellent setting to the flowers. There are three varieties of *C. speciosus*, viz., *C. s. Aitchisonii*, *C. s. transylvanicus*, and *C. s. globosus*, but, though beautiful, none of them are quite as lovely as the type. Although *Crocus speciosus* is the most attractive of the autumn-flowering race, there are several other pretty species well worthy of a place in the garden, since they and the Colchicums are invaluable for giving colour at a season of the year when the majority of plants have passed out of bloom. Of these the following are pleasing: *C. cancellatus*, *C. iridiflorus*, *C. hadriaticus*, *C. lavigatus*, *C. medius*, *C. nudiflorus*, *C. ochroleucus*, *C. pulchellus*, *C. Salzmannii*, *C. sativus*, *C. Tournefortii*, and *C. zonatus*. These bear flowers of varying shades of purple, violet, and lilac, often veined and feathered, and in some white and yellow are the predominating colours. While on the subject of Crocuses a passing reference must be made to the charming early-flowering *C. Imperator*, which expands its delicately tinted buff and lilac blossoms in the time of the Snowdrops.

S. W. FITZHERBERT.

#### COLCHICUM BORNMUELLERI.

A FINE clump of this scarce Meadow Saffron has been much admired here this autumn. It is as large as the finest of the forms of *C. speciosum*, but opens lighter in colour, afterwards becoming a good purple with a white centre. *C. Bornmuelleri* does not open out so flat as *C. speciosum*, and this is an advantage in rainy or misty autumns. Though still expensive, it should soon be much cheaper, as it increases freely. I grow it here in moist peat and sand. It seeds plentifully, but I have not yet had seedlings of a flowering size.

#### ASTER COOMBEFISHACRE WHITE.

ASTER COOMBEFISHACRE is generally recognised as one of the best of our Starworts, though, like the most of these perennial Aster, it ought to be seen as a large bush to do justice to its beauty. It is one of my special favourites, and I was much pleased when Mr. Archer-Hind kindly sent me in

spring a small plant of its counterpart in habit, but of a different colour. This he informed me was called Coombefishacre White. It is now in bloom, and it appears certain that it will be a great acquisition, even in such a numerous family as in the Starworts, whose species and varieties give us such a multitude of forms. The flowers are exactly like those of the original Coombefishacre but of a fine white. When it comes into market and has attained a good size in gardens this new variety will become a favourite Starwort.

*Carsethorn, by Dumfries, N.B.* S. ARNOTT.

#### BESSERA ELEGANS.

THIS Mexican bulb is rarely seen. It has a brownish Brodiaea-like bulb, lax rush-like leaves 3 feet long, and wiry-looking stems 2 feet high, bearing umbels of rich vermillion flowers each three-quarters of an inch long, and averaging twelve to the umbel. It has the habit of *Brodiaea coccinea* or *B. Howelli*. The most interesting features of the flower are the intense vermillion colour of the segments, the purple filaments and styles which project beyond the perianth, and the arsenic-coloured pollen, altogether a curious com-

*Scilla haemorrhoidalis*, a species at one time sent from Grand Canary, where it inhabits a limited area a mile or two north-west of Monte on a precipitous cliff.

G. B. MALLETT.

#### LITTLE-KNOWN GRAPES.

IT is surprising what a great number of Grapes can be placed under this heading. I am aware that the majority are of little or no use for general cultivation, but still I think there are a few which, given a good trial, would compare very favourably with some kinds more extensively grown. A few of the best of a collection I have had under my notice for the last two or three years are mentioned.

*Sin Antoniu*.—This produces fine bunches, somewhat resembling Madresfield Court in appearance. The berries are purplish black, large, and oval. Flesh tender, juicy, and sweet, with good flavour. Like Madresfield Court, it is a bad keeper.

*Chasselas Rouge* forms a medium-sized somewhat loose bunch. The berries are small, red, very juicy, and sweet.

*Chasselas Rose*.—This variety is remarkable for its excellent flavour, not unlike Muscat of Alexandria. Its bunches are large and compact, with large round berries. It has a pale yellow skin. Flesh juicy and sweet.

*Chasselas Napoleon*.—This is one of the best, and deserves to be more extensively grown. It forms a handsome bunch, is a free setter, and the flavour is excellent. Berries oval, of medium size, becoming pale golden when ripe. This was shown with success at the recent fruit show at the Crystal Palace.

*Chaptal*.—This is a white Grape, and not unlike Golden Hamburgh. It forms handsome bunches of good size and flavour, but its flesh is very soft.

*Black Frontignan*.—This is a good free cropping variety of excellent flavour. Its bunches and berries are

of medium size, round, and black. Flesh firm and juicy.

*Madeira Frontignan*.—This produces medium-sized compact bunches with reddish purple berries. Flesh juicy and sweet, and of good flavour.

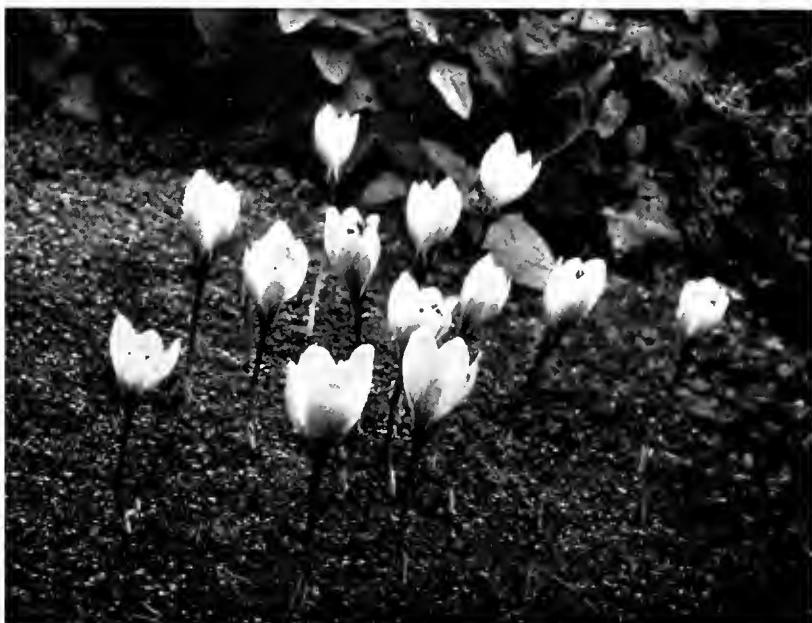

*Meurthe Frontignan*.—This is of excellent flavour, which very much resembles the Muscat. It has medium-sized bunches, with large round berries, which are quite black. Its flesh is very firm and sweet.

*Salamon's Frontignan* is of medium size both in berry and bunch. It is a white Grape of a somewhat Muscat flavour.

*Black Monuhka*.—This produces large bunches and berries, but the flavour is only third rate, and not to be recommended.

*Black Cluster*.—This crops very freely and is a good setter. Its bunches are rather small but very compact. Berries oval and black. Flesh firm, juicy and sweet, and of good flavour.

*Syrian*.—This is a very strong grower, and produces immense bunches. Berries large, oval, and pale yellow when ripe. Flesh very

CROCUS SPECIOSUS: A BEAUTIFUL BUT NEGLECTED AUTUMN FLOWER.

bination of colours in one flower. The umbel is light and graceful, and the flowers are quaint, and on this account the plant is a favourite with those who care for bulbous plants, thriving colonies being occasionally found in obscure collections, but I do not think *Bessera elegans* is generally well known. It may be treated similarly to *Milla biflora* with good results.

#### SCILLA CHINENSIS.

THIS, or *Barnardia scilloides* as it is most frequently called, is a quaint little bulb resembling a Hyacinthus. It throws up several stems a foot high in August, September, and October, terminating in a pretty spike of pale pink flowers, rather densely packed together, but sufficiently open to show the ivory whiteness of the pedicels and that portion of the stem incorporated with the inflorescence. The unopened buds are tipped with green. It is free growing, perfectly hardy, and well adapted for the rock garden or border, but particularly for the rock garden, where it would help to sustain interest when many of its kindred are resting. It is a capital plant for naturalising, also for flowering in company with Colchicums, Crocuses, Sternbergias, &c. Its nearest ally is

firm and sweet. It is a good late Grape, and keeps well when well finished.

*Royal Muscatine*.—This does remarkably well out of doors on a south wall. It develops fairly large bunches. Berries large and round, which when ripe are a beautiful amber. The flavour is rich and delicious.

*Prunus* is a fairly good black Grape, of medium size, and a good cropper. The flesh is firm and sweet, with a peculiar but not unpleasant flavour.

All the above are grown in cool houses, except West's St. Peters, which requires a high temperature to develop it perfectly.

E. HARRISS.

The Royal Gardens, Windsor.

### BUSH APPLE TREES.

THE Apple is the most important fruit grown out of doors in this country, and as in the case of other fruits the southern and warmer parts are the most suitable for its cultivation, but in the more northern and cooler parts with reasonable attention the results are frequently good. I believe that in warmer parts in favourable seasons well grown Apples bear fruit little inferior to that from the most favoured quarters of the world. The cooler parts of the country can never be expected to produce such large crops as in more favoured counties. The Royal Horticultural Society wisely considered this point at their autumn fruit exhibition at the Crystal Palace by having classes for special districts. From

most districts  
well grown fruit  
has come at  
times.

The season for Apples is a long one, well ripened and carefully gathered fruit keeping well in a properly constructed fruit room all the year round, but a reasonable period is from August to April. After the stone fruit season in autumn, and till early forced Strawberries are ready, few home-grown fruits are available, and it is then that good Apples are invaluable. Their colour is welcome on the lunch and dinner table, and with regard to wholesomeness they are unexcelled, whilst for cooking they

may be used in as many ways as any other kind of fruit. In the case of some varieties, the fruit as soon as it is large enough is ready for use, and over-cropped trees may be thinned with advantage.

A month from now (September 30) will be the beginning of the planting season, by which time wood and foliage of the trees will have matured. Before planting time ground on which trees are to be planted should be trenched 2 feet deep at the least. This may appear unnecessary, but the trees will show

the good effect of doing this thoroughly. A good trenching once will last a life time.

Bush trees in their earlier stages are grown and trained as pyramids by nurserymen, i.e., grafted low down near the ground. The first year's maiden growth is pruned to within a foot from the graft, and the leading growth pruned each year to within a foot of that of the preceding year. Side growths are left 9 inches long. Such trees are excellent for planting after the third year. These side growths in after years, with others secured in the same way after planting, form the frame of the tree, from which growths multiply with age. Thinning out is done at pruning time to let light and air into the centre of the trees. I do not attempt to prune Apple trees, except espaliers, on the spur system, but rely on fruit buds being formed on branches. The branches are reduced in number by pruning to prevent overcrowding. Excessive pruning of Apple trees creates canker, while free growth prevents it. Bush trees have the advantage of being easily kept in position after planting by staking. They are convenient also to manage, such as freeing from insects, pruning, thinning the fruit, and gathering. Too much cannot be said for thinning. No matter what the shape of the tree, if more fruits are swelling than can be developed to a proper size, thinning should be done, and in any case deformed useless rubbish should be taken off. I do not think Apple trees ever looked worse in the month of June than they did this year. Fruit that escaped the spring frosts was

same conditions. So far as I know there is only one place where they will not thrive, and that is on grass; there I think no tree will fruit satisfactorily, as is so often shown by the miserable trees one frequently sees on grass land. It is condemned at the Woburn fruit farm.

## THE WALL GARDEN.

### WALL GARDEN - MAKING.

#### I.—INTRODUCTION.\*

WALLS in the garden are often a necessity, not only on sloping ground, but sometimes even on fairly level spaces. The construction of such walls and the process of adorning them with all kinds of suitable vegetation is now generally termed "wall gardening." That in connexion with such work an enormous number of problems may occur, according to the varying conditions of position, requirements, climate, surroundings, &c., is only natural, and the object of this and the following essays will be to give practical hints and suggestions on this subject of wall gardening in its various forms.

A wall garden and a rock garden should not be confounded, nor should there, in my opinion, be any attempt at amalgamation, a step which could only end in failure from a

picturesque point of view; in fact, I feel strongly convinced that both should be as distinct as possible from each other. A wall in its structure should be a wall plain and simple, however much we might vary its adornment by plants. But a rock garden should contain either natural rocks or what appears to be such; it should, in fact, be as irregular as possible. Regularity in a rock garden would be fatal to its purpose, i.e., the representation of a piece of wild, rugged Nature. For the same reason, too much regularity in a wall would spoil its nature,

and of all structures in the universe none are more deplorably repulsive in their effect than the so-called "rock walls," which resemble neither wall nor rock, but are bald and ugly.

When speaking of regularity in a wall garden, I do not for one moment wish to imply that the walls must always be in straight lines. On the contrary, it may often be most desir-

\* With this article we commence a series of essays written by Mr. F. W. Meyer, of Exeter, on the interesting subject of wall gardening. As these contributions are based on practical experience, we hope they will prove useful to readers of THE GARDEN.—ED.

BUSH APPLE TREES IN FLOWER IN THE LANGLEY NURSERIES OF MESSRS. J. VEITCH AND SONS.

stunted and much bruised. The foliage, too, was crippled with insects and mildew, but by removing the deformed fruit and reducing to one where they were in clusters the result is on many trees a useful crop. The rainfall of August and September much assisted them. Some gardeners say they "do not have time to thin; while they would be thinning weeds would be growing." I manage to thin Apples, and get at the weeds, too.

Bush trees can be grown in all positions where standards would succeed, and under the

able to make them in curves, but their general structure should be regular and uniform in all but the planting, which will be found most effective when varying as much as possible.

The accompanying illustration shows a very striking case in point. It was prepared from a photograph which, by the kindness and courtesy of Sir Warwick Morshead, I was permitted to take at Tregaddick, in Cornwall. Here the ground immediately in front of the house slopes to such an extent that it was absolutely necessary to build a curving, retaining wall to support a plateau sufficiently large to allow carriages to turn with ease and without danger. It is a dry wall built of granite, and sufficiently deep to allow for a narrow piece of lawn to slope inwards, *i.e.*, towards the house, between the gravel plateau and the wall itself. The joints are filled with soil instead of mortar, and how well plants delight in just that kind of position may be gathered from the present illustration and also from a previous one published in connexion with my notes on wall gardening in September (see THE GARDEN, September 20), which depicts another portion of the same wall. In the present illustration a luxurious group of fine Carnations (ten years old) fringes the top of the wall, while lower down are Ferns, Alyssum, Antirrhinum, Sedum, Eschscholtzia, Arabis, Valerian, &c., in great profusion.

#### ADVANTAGES OF A WALL GARDEN.

Rock gardens and wall gardens may be said to supplement each other. It often happens that a position most unsuitable for the one is at the same time most suitable for the other, and vice versa. Thus in a small formal garden, where rockwork would be out of place, the owner need not on that account give up the idea of growing such of the choice mountain plants as would require the support of stonework, but he might construct a wall garden instead, in which the majority of such plants would thrive admirably if well chosen and properly planted.

If the formal garden is bounded by retaining walls, forming either a terrace or a boundary, there is no reason why such walls should not be made to yield a brilliant display of colour, and by having an eye to successive effects they might be made attractive practically all the year round. Many alpines from high altitudes, and even some of the choicest gems of the mountains, will succeed in this position between the joints of the stones better than anywhere else.

Another most important advantage is that if our favourites are planted in a wall we may have them under our more immediate notice, as in the raised positions they would be nearer to or even on a level with the eye. Then, again, in the case of overhanging plants, their prostrate or pendent shoots can never be seen to better advantage than when gracefully suspended from a wall. Even plants which

we are generally accustomed to grow on level ground, as, for instance, the Carnations shown in the illustration, gain considerably in effect by such an elevated position. On level ground the hanging down of the shoots of Carnations becomes a nuisance, as they have to be tied to sticks, &c., but the Carnations shown in the illustration look more graceful on the wall

rock garden could possibly be a real success, it would have been better by far had such rockwork never been attempted, but given place to simply a plain wall, which could have been erected at less than a quarter the cost by an ordinary mason or even intelligent labourer. It does not follow that a wall garden may be made a success in any position. On the contrary, it would be sadly out of place in the midst of very irregular or undulating surroundings, especially if it be a straight wall, and if this should intercept the view from any important position as seen either from the house or from such parts of the garden as would be much frequented. In such a position a wall garden would be even worse than rockwork within a formal garden.

#### THE MOST SUITABLE SITE FOR A WALL GARDEN.

We may, broadly speaking, accept the principle that a wall garden will be at its best only when constructed on more or less regular lines as a terrace wall, a boundary wall, or a similar position. There may be exceptions, of course, but on the whole a site connected with formal gardening of some kind will be found to be best, even if the formality is confined to the immediate surroundings of the house only. It very often happens that owners of gardens have long straight borders only 3 feet to 5 feet wide running parallel with a straight walk more than 100 feet in length, and that they desire to use such border for rockwork. Now in such a position even the most skilful artist in rock building will fail to produce work which would represent natural rock in an entirely satisfactory manner. The space would be too narrow in proportion to its length to admit of the necessary variation so essential to a natural appearance. But for a wall garden such a site would be just right, in fact nothing could be better. If it should be desirable to devote the entire border to

alpines or other mountain plants, we may build a wall which would appear as if it had natural rock for its foundation. This is easily effected by scattering a few rough weather-beaten stones of different sizes over such a border, and if skilfully placed and half buried in the ground these stones will convey the idea that the wall was built on the top of natural rock which is cropping up through the surface here and there but reaches down to depths unlimited below the ground.

This would be perfectly natural in appearance, and in such a case we might combine rock gardening and wall gardening with success; but if the reverse should be the case, *i.e.*, if—as is unfortunately still too often done—rockwork should be arranged on the top of a wall the result would be ridiculous, from the fact that such a thing could not possibly occur in Nature.

Elmside, Exeter. F. W. MEYER.  
(To be continued.)

PORTION OF WALL GARDEN IN THE GROUNDS OF SIR WARWICK MORSHEAD, TREGADDICK, NEAR BODMIN (NOTE THE CARNATIONS IN FLOWER ON TOP OF THE WALL).

than could possibly be the case anywhere else. Moreover, their flowers are at the exact height of the average eye, and their perfume can be enjoyed without stooping or even without lifting the blossoms, an advantage which should not be overlooked.

Still another advantage of wall gardening is a maximum of effect at a minimum of cost. Building a wall is easier and cheaper than constructing a good rock garden, and the plants growing in the wall are easily kept in order, requiring but little attention.

#### WALL GARDENING AND ROCK GARDENING COMPARED.

Rockwork, when really well arranged, may be made a most charming feature in the garden, but when erected by incompetent hands, without regard to good taste or to Nature's simple laws, becomes repulsive. If the constructor of such rockwork does not possess the ability of imparting to his work that natural appearance without which no

## GARDENING OF THE WEEK.

## KITCHEN GARDEN.

**S**ECDOM do we see the crops of winter vegetables looking better than at this season, especially those on light dry soils, and the past spell of dry weather has done much to improve matters even in the low lying districts and on stiff land. Providing we are favoured with a fine autumn to enable the growth of all kinds of green vegetables to become well matured before we experience any very severe weather there should be abundance of most things.

Turnips are particularly good this season, the dull showery weather suiting them. The earlier sowings should be lifted immediately they are of fair size and stored for use as required. Guard against keeping them too close together. The right method is a layer of bulbs and a layer of sand or cinder ashes, and place them under a north wall.

Keep the soil frequently hoed among successive crops, and the very late sowings should

moist for about a week or ten days before placing them in heat. The warmest end of the Mushroom house should suffice for this.

## THE FRAME GROUND.

All well ordered gardens should contain a place, sheltered, but exposed to the south, for the protection and forcing of the various kinds of vegetables. Where a succession of high-class produce is required it is an absolute necessity. Now is a good time to clear up and make one's plans for the following year. The old hot-bed should be turned over, and this makes excellent material for nearly all crops, both in the kitchen and flower garden.

The frames and lights should be well washed and repaired, and in a very short time fresh material for the new hot-beds should be prepared and made up for starting the various crops, one of the first being Asparagus. There is no reason why this delicious vegetable should not be had by the use of fermenting material and cold frames from November till the time comes round for cutting in the open. Attend to the blanching of Endive, both the broad-leaved and curled varieties, also Lettuce, but keep it well tied

no water will be necessary at present. Plunge the pots in cocoanut fibre, with a bottom heat of about 65° or 70°, and cover the bulb with a flowerpot. The American varieties are imported in December and January.

## CANNAS.

These are useful for winter-flowering, and are valuable as decorative plants for rooms. Now is a good time to put in sucker cuttings for that purpose. We usually obtain at this season strong sucker growths from plants growing outside in beds. Fill 4½-inch pots with a compost of loam, leaf-soil, and sand, with an addition of dried horse manure. Place the cuttings singly in the pots, making the soil quite firm, and give good drainage. They should be then well watered and placed in a shady and warm position in the propagating house, where they will root readily, after which they should be gradually hardened off, for the more sturdily they are grown the more serviceable plants will they make. When the pots are well filled with roots, liberal feeding is of great advantage.

## CINERARIAS.

The earliest batches of these that are being grown to flower in November and December should be removed to a cool and airy house. Assuming that the pots are well filled with roots weak liquid manure should be given. Later batches should be potted into their flowering pots. Plants required for house decoration should be grown in small pots; the foliage will be firmer and the growth more woody, consequently they will stand rougher usage than plants in larger pots with luxuriant growth. Plants in small pots need more care in watering.

## BEGONIA GLOIRE DE LORRAINE AND ITS VARIETIES.

These useful winter-flowering plants are now growing freely, and will require tying and slinging to a centre stick. I prefer green raffia for slinging, as by using this the ties are almost invisible. This plant requires liberal treatment when the pots are full of healthy roots; it is surprising how much feeding it requires. Clay's Fertilizer and cow manure alternately we have found most satisfactory. The same remarks apply to other winter-flowering Begonias; they all thrive in a warm moist atmosphere.

## NERINES.

As the flowering spikes are being pushed up light feeding should be given them. Give water at the roots with great care, as excessive moisture must be avoided or disaster will soon follow.

Light feeding should be continued during the growing season. When in full flower Nerines are of the most beautiful of greenhouse bulbous plants, and flowering as they do during autumn and winter deserve to be more largely grown.

Wexham Park, Slough.

JOHN FLEMING.

## THE FRUIT GARDEN.

## EARLY VINERIES.

VINES that are to be started by the end of November should now be quite matured, and if they have not yet been pruned it should now be done. Thoroughly cleanse the structure by washing woodwork with soapy hot water. Lime-wash the walls and take the opportunity of repainting if needful. Once pruned the vines should be relieved of loose bark, but in doing so bear in mind that severe peeling is hurtful, as it exposes the rods to the weather. The vines should also be well cleansed by carefully washing them with a half-worn spoke brush with a moderately strong solution of Gishurst Compound and soft water used whilst hot. This, if thoroughly worked into the crevices of the spurs, &c., will eradicate red spider. Afterwards remove the surface of the border, which it is assumed for early forcing at least is placed inside, and top-

A PRIZE DESSERT TABLE AT SHREWSBURY FLORAL FETE, SHOWN BY MR. G. MULLINS, EASTNOR CASTLE GARDENS.

be thinned, but left about as thick again as is generally advised. Apply frequently slight dressings of soot and a quick acting manure, and keep the soil stirred often with the Dutch hoe. The late batches often prove to be invaluable after a severe winter, as by drawing a little soil over the bulbs at a later period these will generally come through quite unharmed.

Seakale has made splendid growth this season, but the crowns are very late in ripening. No time should be lost in preparing the first batch for forcing, as Seakale does not start away freely unless a short season of rest is given to it. The foliage should be removed as it shows signs of decay, the roots lifted and left exposed on the ground for a few days, taking up sufficient only for the time being at this early season. A fairly strong heat will be necessary to start it into growth, the crowns should be syringed two or three times daily, and all air and light excluded. I have found that excellent kind, Lily White, forces better than the ordinary variety.

Rhubarb should be treated much in the same way, except that this requires even a longer rest. Choose an early variety. The old foliage should be cleared away, exposing the crowns as much as possible some days before lifting. The roots should be taken up carefully, but these are best kept

during fine weather. Good salad is generally much in request at this season of the year.

E. BECKETT.

*Aldenham House Gardens, Elstree, Herts.*

## INDOOR GARDEN.

## FERNS.

At this season less atmospheric moisture must be given and the plants frequently overhauled and all dead and decaying fronds removed. Allow plenty of space between the plants, as this will keep damping of the fronds in check. Plants that have been growing all the season, and have their pots well filled with healthy roots, should be given a stimulant. Weak liquid manure made from Clay's Fertilizer or guano we have found most beneficial. Water at the roots must be given sparingly during winter. Many of the Adiantums that have been used in the cool houses should be brought back into warmer quarters.

## TUBEROSES.

The African bulbs are now coming to hand and may be potted singly in 4½-inch pots. They like a compost of fibrous loam and leaf-soil, with sufficient sand to keep the soil porous. The compost used should be in a moist condition, and

dress it with fresh compost enriched with a suitable fertiliser. Keep the house perfectly cool until required to be closed for starting the Vines.

#### PEACHES AND NECTARINES.

Early trees that have matured their wood and dropped their leaves should without delay be prepared for next season. Untie the branches and thoroughly cleanse the trellises, woodwork, walls, &c., of the house. If the trees have been treated as advised in previous calendars they will be well furnished with fruitful wood, and no pruning will now be required, but should young wood have been too thickly laid in it should be thinned by cutting away the weakest growths sufficiently to allow the best bearing wood being trained from 6 inches to 7 inches apart. The wood if crowded cannot mature properly or become studded with good fruit buds. Though it is too late now to wholly remedy mistakes of this description that were made during the growing season, a repetition of the evil should be guarded against. Carefully wash the trees with a weak solution of Gishurst Compound, XL All Insecticide, or any other approved insecticide, but in doing this it should be remembered that the buds of these fruits are injured by powerful dressings. In training the trees distribute the bearing growths equally over their entire surface, so that a regular crop of fruit may be expected and an even supply of young wood ensured next year. Complete the preparation by removing with hand forks the immediate surface of the borders, which, if the trees are satisfactory, will be filled with fibrous roots. Give a top-dressing of fresh compost formed of sound loam, fine mortar or old plaster rubble, wood ashes, and bone-meal, made quite firm, and lightly mulch with short litter.

#### LATER TREES.

About this time—i.e., when the foliage is matured and falling—is the most favourable for rectifying defects of any kind relative to the roots of the trees or their borders. In the case of trees that are making gross, unfruitful wood, carefully remove the soil from amongst their roots, and after slightly shortening any very strong ones, relay them in layers near to the surface of the border. Embrace this opportunity of improving, if it is desirable, the condition of the soil by adding suitable ingredients to suit the trees. Use the compost in a fairly dry state and make it quite firm, and after mulching the surface of the border give it a good watering to settle the soil about the roots. Any planting that is anticipated should be done as soon as the trees are fit for lifting. We make a practise of purchasing trees to take the place of those declining in health a year or two previous to uprooting the condemned ones, and plant them against an outside wall to get established and in a fruitful state before placing them indoors. It will, of course, be understood that trees treated in this manner have gradually to be prepared for early forcing. Amongst good varieties for growing under glass are, of Peaches, Amsden June, Hale's Early, Early Grosse Mignonne, Crimson Galande, Bellegarde, Dymond, Noblesse, Royal George, Violette Hâtive, Barrington, Raymaeker's, Gladstone, Exquisite, and Sea Eagle; of Nectarines, Cardinal, Early Rivers', Lord Napier, Dryden, Stanwick Elrige, Pitmaston Orange, Humboldt, Pine-apple, Spenser, and Victoria.

#### FLOWER GARDEN.

##### WILD GARDENING.

WHERE the delightful practice of wild gardening is indulged in the present time will be a busy one in preparing pictures for the spring months. In the orchard, especially the orchard that is retained because of its picturesque appearance, whose trees are preserved because of their green lichen-covered trunks and bright ornamental fruits rather than for their economic value, many desirable bulb effects will suggest themselves. Natural informal stretches of Snowdrops, Crocuses, Narcissi, and Tulips to suc-

ceed one another, with here and there groups of blue Appenine Anemones, *Chionodoxa*, *Fritillarias*, and *Camassias* cannot fail to appeal to and render one enthusiastic. In grouping bulbs the chief idea should be to avoid hard lines of demarcation between the colours, and at the outskirts to let them disappear quietly and not abruptly into the space around. To obtain a natural grouping one must have the grass as short as possible, and then, having determined the shape and size of the groups, throw the bulbs in large handfuls in the direction the effect is desired; men follow with trowels and plant them exactly where they have fallen. By this method stiffness and formality are avoided. Where the bulbs are grown the grass should be mown quite closely, so that in the spring the flowers can be seen to the best advantage. For growing in the deep shade of trees there is no bulb better than the Wood Hyacinth or Bluebell (*Scilla nutans*). For similar places the Grape Hyacinth (*Muscaris botryoides*) has also much to recommend it. In the deep shade and shelter of evergreen Oaks there are also colonies of beautiful Cyclamen which have been successfully naturalised. Before planting the tubers the ground should be improved by

manuring and enriching with fresh soil, and though the bulbs enjoy moisture at the root they cannot thrive on wet sodden land, so that good drainage is essential. Unlike Cyclamen *persicaria* the tubers of all the hardy species must be planted fairly deep below the surface.

THE IVY-LEAVED CYCLAMEN (*C. HEDERÆFOLIUM*) is one of the best for naturalising, because of its pretty foliage; it is attractive during the winter and spring months, while in the autumn its flowers, which usually are profusely borne, are delicately beautiful. The round-leaved Cyclamen (*C. Coum*) is adapted for planting in the shade of trees, and also *C. europaeum*, which is distinctly fragrant. *Camassia esculenta* is a splendid bulb for naturalising, and a bold group of it in flower in June is a fine sight; the flowers are a beautiful deep blue colour and well above the grass. In selecting a habitat for it in some deep rich soil it should be borne in mind that the grass about it cannot be cut until late in summer. Such things as Crocuses, Narcissi, and Tulips ripen off comparatively early, but the *Camassia* does not.

While preparing these delightful features of flower life in the wild parts of the garden and the orchard one should at the same time note old trees and rough stony bits that would be improved by some suitable creeper or climber. *Clematis Flammula* or *Polygonum baldschuanicum* festooning and hanging in a graceful mass from some old gnarled Apple tree is an object of great beauty in the late autumn months, and one that never fails to

GRAPE MUSCAT OF ALEXANDRIA.

elicit admiration. A rough bank or stump of tree, by covering with Honeysuckle or Vine, can be made most attractive.

HUGH A. PETTIGREW.

#### GRAPES FOR EXHIBITION.

FEW seasons in my recollection have furnished better opportunities for judging of the merits of black Grapes for exhibition than the year now drawing to its close, and few seasons also do I recollect where the conditions conducive to the perfection and finish of the Muscat and other white Grapes have been more unsatisfactory. This is a clear proof, if proof were needed, to show that black Grapes can be grown to perfection of colour and bloom under cooler conditions and in the absence of less light and sunshine than can the Muscats and other light-coloured Grapes, for the latter, with very few exceptions, have not been conspicuous during the past year for high quality and finish.

##### BLACK GRAPES.

Amongst black Grapes for exhibition purposes Madresfield Court, I think, stands prominent. Those who succeed in growing this variety to perfection as to size of bunch and berry, colour and bloom, may confidently rely on favourable notice at the hands of the judges whenever and wherever it is exhibited.

GRAPE MADRIFIELD COURT.

Muscat Hamburgh follows very closely in order of merit. It is even more difficult to grow and finish to perfection than is Madriffeld Court, and in consequence few growers attempt its cultivation. All the more credit is due to growers who are able to place such splendid samples of this Grape on our exhibition boards as Mr. Goodacre, for instance, has done this year, and notably so at the Shrewsbury show. Mrs. Pince is an excellent and valuable black Muscat Grape. It succeeds well even in an unheated viney, but it is, unfortunately, almost impossible to colour it well. Yet this can be accomplished, as is occasionally evident at our fruit exhibitions, and notably so at Shrewsbury this year in the fruit Coronation class for Grapes, forming, as this variety did, one of the best dishes in Mr. Lunt's collection. The gardeners of the past generation have more or less failed in the culture of these two splendid Grapes, Muscat Hamburgh and Mrs. Pince. Let the rising generation find the reason why, and help by this service to secure to fruit lovers the enjoyment of certainly two of the highest quality Grapes in existence. Coming now to the more prosaic varieties of black Grapes, the first place must be given to Black Hamburgh. When well grown this is in many respects the most useful of all Grapes. Of this there are at least three distinct varieties,

sequence of its quality being only second or third-rate, and the uncertainty of its setting its berries well, it is not often grown. Amongst black Grapes of recent introduction, Appley Towers is a variety that has secured general recognition as being a useful sort. It has been extensively and successfully exhibited this year. It is somewhat of the type of Alicante. I may be permitted to remark here that I have too frequently noticed in judging Grapes the great number of points of excellence lost to exhibitors by defective thinning of the berries, and this is especially the case with the large black Grapes. The fault is nearly always that of leaving too many berries on the bunch, and many points of merit are lost in consequence.

#### WHITE GRAPES.

Of white Grapes for exhibition Muscat of Alexandria is undoubtedly still the best, and when grown and finished to perfection it is not too much to say of this Grape that it is not only the most popular, but that it is the best of all Grapes with regard to quality, richness of flavour, and beautiful appearance, yet how seldom is this Grape seen at its best. Not six growers in ten give the fruit time to properly ripen before it is cut. Some of the best finished Muscats I have seen for a long time were exhibited at the recent show of the

namely, the Frankenthal, the Mill Hill, and the Black Hamburgh. The latter is represented by the well-known Vines at Hampton Court and Cumberland Lodge. For exhibition purposes the Frankenthal, in my opinion, is by far the best. It is large of bunch and of berry, and carries a colour and bloom when properly finished that are exceeded by few Grapes.

#### LATE VARIETIES.

Of late varieties of black Grapes for exhibition, Alicante perhaps ranks as high in favour as any. It is easy of culture, of fair quality, shapely bunch, good sized berry, and usually carries a lovely bloom. Gros Colman runs the Alicante very close in order of merit in the opinion of judges; indeed, when well grown it would take precedence in the opinion of some. Gros Maroc, in consequence of the size of its berry and the wonderful colour and bloom it puts on so early in the season, is a useful variety to grow for exhibition, especially for the late summer and early autumn shows. Alnwick Seedling is one of the handsomest of all late Grapes, but in conse-

Royal Horticultural Society at the Crystal Palace. The bunches were of average size, berries well developed, the colour and quality perfect—a lovely transparent amber. Duke of Buccleuch ranks very high as an exhibition Grape, and is one of the most valuable to have in a large class. Golden Champion runs it very close, but the former is the more imposing Grape. A variety that has come to the front conspicuously this year at our exhibitions is Chasselas Napoleon. The bunch is long and tapering, berries large, and when well grown of noble appearance. As an exhibition Grape in this section it is likely to prove in the future a strong rival to Buckland Sweetwater and Foster's Seedling. Golden Hamburgh, also in this section, is a variety that should not be lost sight of. It is of easy culture, much like the Black Hamburgh, and when well finished is one of the prettiest and sweetest of Grapes.

OWEN THOMAS.

#### ROUND ABOUT A GARDEN.

##### THE NEGLECT OF WHITE.

THE more one sees of princely gardens the more convinced one grows that the great fault of the expert horticulturist is his neglect of white in the arrangement of colour. Wherever a combination of beautiful tints fails quite to satisfy the eye it is almost always white that is wanting, and where the brilliance of a flower-bed positively distresses, white would have been the remedy. Plenty of white Tulips and white Hyacinths are the secret of a lovely spring garden. You can have it as bright as you like with reds, yellows, and blues, or you may play subtle chords of softer shades; but white is the natural accompaniment of all colour music, and a flower-bed gains as much from the addition of white flowers as our pictures from the fair white margins in which we frame them.

##### SIMPLE COLOUR EFFECTS.

For producing the simplest effects white is indispensable, because there are no combinations of two colours only which satisfy the eye, unless white be one of them. You may travel far and inspect many summer gardens without discovering any flower-bed of blended hues which is so completely lovely as one filled with white from edge to edge, with scarlet-carmine flowers—there are some Begonias which serve the purpose admirably—dotted about in it. Among your spring flower-beds, again, arrange the rest how you like, but try the experiment of filling one entirely with dark blue and white. You will find that when your eyes range round the array of many colours they always return to rest upon this bed with genuine pleasure.

##### FOR A SPRING BORDER.

Another fine but simple effect of white is best seen in the spring garden also, if you plant the bulbs of white Narcissus thickly among blood-red Wallflowers, edging or surrounding them with a belt of blue Forget-me-nots. The contrast between the pale blue of the Forget-me-not and the deep red of the Wallflower is as accurate as that between blue Lobelia and orange-crimson Nasturtium; and the white Narcissus adds to one combination exactly what the white Marguerite gives to the other, the one touch needed to make the harmony of colour complete in itself. This, indeed, is the real value of white that, being itself conspicuous for the lack of all colour, it gives the coloured flowers with which it is placed the full credit for their lovely hues. It is the ground level, so to speak, of colour, and,

just as you cannot realise the height of trees unless you can see the ground from which they spring, so you cannot fully appreciate the full extent of a colour's beauty unless there is white alongside to measure it.

#### A PLEASING MIXTURE.

Fortunately almost every flower has its white variety—as though Nature foresaw the great demand which there ought to be for white in gardens—and you can almost always rely upon plenty of pleasure from mixing together any two kinds of very variable plants, the white being always numerous enough to prevent any clashing of tints. Thus one of the prettiest effects for late spring and early summer may be made by filling a flower-bed with dwarf Snapdragons raised from good mixed seed, and planting mixed Spanish Iris bulbs freely between them. The result will be a surprising medley of harmonious colours in such endless variety that you never tire of looking at its kaleidoscopic combinations, without a touch of discord anywhere.

#### THE USE OF DULL COLOURS.

We neglect dull colours in flowers—greys, lavenders, and browns—almost as unreasonably as we stint the garden of its necessary white. Most of the dull flowers are beautiful in themselves or sweetly scented; but their value in a garden is chiefly as foils to brighter neighbours. Look at a carmine flower by itself and then place it with the grey of any woolly leaves, and you will see it go up several times in colour; add white and you have a delicate and perfect harmony. The same carmine and white again make a pretty contrast in themselves; but add the rich brown of, say, Calceolaria and the brilliance of the combination is doubled, though you have only added a dull colour to it. In the same way to discover what a grand colour true scarlet is, give it lavender-grey as a foil and add white to isolate the contrast. But I have lectured more than enough about colours.

#### CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

#### STREPTOSOLEN JAMESONI.

[To THE EDITOR OF "THE GARDEN."]

**S**IR,—I have been recently asked advice respecting this lovely greenhouse plant. From enquiries which have reached me at various times it would seem that there is some difficulty in getting it to flower freely, and indeed this was once the case with me. No plant is so easily grown. It roots as readily as a Coleus, and will quickly reach 4 feet or 5 feet in height if allowed to do so. Any ordinary soil seems to suit it, and delights to grow in the open air during the summer months; in fact, if placed alongside the ranks of Chrysanthemums and accorded the same kind of treatment, without the pinching, the best results may confidently be looked for. If, however, good flowering plants are required for the Easter or early summer display do not pinch, but simply let the plant grow in its own way, giving the leaders the support of a neat stick. It is one of the grossest feeding plants I am acquainted with. The pots are soon packed with white roots, when it will require a very large supply of water and frequent doses of liquid manure. I have seen specimen plants of it which, of course, had been brought about by pinching, but this was not carried on as one would do in the case of Fuchsias and Coleus; plants expected to flower, say in May or June, should not be pinched later than the previous autumn or some time before Christmas. In order to allow the plants to make well matured

growth I question whether bending and tying into the desired shape would not produce better results. However well plants may look grown in this way, they are far better when allowed to grow naturally and then taken to the greenhouse and tied up to the rafters or wires under the roof glass. The growth must hang loosely over the paths. In this way there are few plants to equal it. These, hanging over side stages filled with well flowered plants of its relative Browallia speciosa major, have a very fine effect. It is always admired by those visiting these gardens. I strongly advise growing the plants naturally, and under no circumstances should they get dry at the root or the flower buds will fall wholesale.

THOMAS ARNOLD.

*The Gardens, Cirencester House.*

#### PRUNING PEACH TREES.

[To THE EDITOR OF "THE GARDEN."]

SIR,—In pruning Peach and Plum trees should the new shoots with yellow pith be cut off, as one would do in the case of Roses? Is yellowness of pitch a sign of the shoot being injured?

FENMAN.

[In pruning Peaches leave the best ripened wood, but remember that the fruit of the Peach and Nectarine is produced on the new wood of the current year's growth. You cannot prune the Peach in the same way as the Rose. The Plum differs from the Peach in that the fruits are borne on spur growths, that is, growth stopped the previous year, or even a longer period, to say four to six buds. Any shoots not needed for extension are stopped in the growing season, and are then termed spur growths, and in the case of Plums they fruit freely. By the term shoots for the extension of the tree we mean young trees that one wishes to extend, and shoots such as terminals, or those at the sides that have room to develop. On the other hand, the above advice refers to wall trees. In your question you do not say if your Plums are or walls; we presume they are. Of course the Peaches are, though the Peach is grown as a bush in favourable situations. If the Plums are bush or standard trees, cut out useless growth, that is, to thin the trees, but gross or strong wood in Plums is not fruiting wood. It does not always follow that yellow shoots as you describe are not well matured, as in many cases the wood is shaded, and then it cannot ripen. If the wood is firm and the buds prominent we do not advise its removal, unless not required for extension. With regard to shoots with yellow pith, much depends upon the size and where the shoot is placed. Our advice is to thin out, leaving plenty of new wood for next season's fruiting, and in so doing cut away the worst placed and unripened wood. More good follows thinning in the late summer than severe

pruning in winter, as the wood by so doing gets better matured, and by early thinning and summer stopping yellow shoots will be few in number. The Plum to be profitable must each season have a good lot of young wood for fruiting. This applies equally to walls, as unless new wood is encouraged the crop is poor. You must not rely upon old wood in Plums for a crop. We now come to the pruning of the Peach. This is different, as few fruits are produced on what is termed spurs. The amount of wood to leave for fruiting should be decided in early summer, as with wall trees it is necessary to thin freely in May and June, that is, to leave the best placed shoots at the base of the parent shoot and the shoots just beyond the fruit and the terminal one. Then when the fruits are gathered the shoots that have borne fruit may be cut out. This leaves the two good ones left at the base, which have been tied or nailed to the wall as fruiting wood for next season. You see by this there is always a system of extension going on, and in the case of main shoots or terminals or side growths to fill space these must be left from the start. You may shorten back now but not remove; in fact, in the case of the Peach, the more you extend the trees the better, but do not crowd the centres. The Peach grown as a bush needs different treatment. Cut out old wood that has borne fruit, thin out weak shoots, and do not crowd in any way. If the trees are large enough shorten terminal shoots and thin the centre. Far better thin trees during growth and remove a shoot misplaced than cut hard in winter; the latter often causes gumming and canker. Young trees are ruined by severe pruning. We advise extension.]

GRAPE GROS COLMAN.

## CUTTING THE FOLIAGE OF HARDY PLANTS.

[To the EDITOR of "THE GARDEN."]

SIR,—I am much indebted to Mr. Arthur Goodwin (page 203) for his answer to my previous note on this important subject, and I had hoped that others would have expressed their views. Now hardy plants are so generally grown many find the question of cutting off the foliage and when to do it a vexed one, and I hope the question may be well discussed, for I feel sure that many plants are much harmed by injudicious treatment with regard to their foliage. I am pleased to note Mr. Goodwin agrees in the main with me on this point. Perhaps I may be permitted to point out that this question of cutting down needs some explanation, for there is a difference of opinion as to what cutting down is. One may think it sufficient to cut the stems just below the flowers and where the main leaves begin, while another would say this was only partial, and the stems should be cut off close to the ground.

I am quite convinced from experience that cutting off the stems half-way down, and thus giving extra food to the plant, will induce new growth and a crop of bloom in late summer.

Since Mr. Goodwin's letter appeared I have had an opportunity of seeing large borders of hardy plants at Didlington Hall, Norfolk. Here one border is 430 yards long, and at Hackwood Park, Basingstoke, there is a border on both sides of the central walk in the kitchen garden 280 yards long. In both places many kinds are grown, and I noticed that Delphiniums, Rockets, &c., were only partially cut down. Upon asking why the stems were not cut close to the ground, I was told that it would weaken the growth next year and soon ruin the plants. I have met with similar instances.

I can see no advantage in cutting close to the ground, for beds may be made bright by treating them otherwise. I had ample evidence of this in the Didlington Hall Garden.

J. CROOK.

## MISCELLANEOUS.

### HOT WATER BOILERS.

**W**E notice in one of our contemporaries an account of Mr. Louis Pearson's (of Beeston) paper on "Hot Water Boilers," recently read before the Institute of Heating Engineers. Many of the technical details would probably not interest our readers, but there are several hints useful to those interested in horticultural work. In his paper, Mr. Pearson speaks first of the similarity between the modern sectional cast-iron boilers and those in use twenty years ago, and gives illustrations of "Wright's Flame Impact," "Witherspoon's Red Rose," and "Foster's Terminal End Saddle," all made twenty-five years ago. He then goes on to show that these old boilers were both economical and efficient, but they were discarded on account of their faulty jointing and unequal thickness of metal, both of which defects have now been overcome in the modern boilers. He makes a strong case out for cast-iron boilers in preference to wrought iron and steel, as the following will show: "Cast-iron boilers can be made in sections, which enable them to be fixed in positions where wrought boilers could not be. It also enables the fire-box to be made in deeply corrugated or tubular forms, which not only present a much larger surface to the direct action of the fire but also tend to check the flow of gases and mix them thoroughly with the oxygen, thereby causing better combustion and economising fuel."

"Cast-iron is also much less affected by oxidisation, which is a great consideration in our climate, and where many boilers are not at work for more than seven months of the year, for boilers, like men, rust out more quickly when idle than when at work. Experiments made by

the Philadelphia Scientific Institute show that as a transmitter of heat cast-iron is more efficacious than wrought iron by over 10 per cent., principally on account of its being more porous, but I think the chief reason for the greater economy of cast boilers is due to the corrugations and the tubes that can be readily and cheaply placed in the fire-box, which not only add very largely to the direct heating surface but break up and thoroughly mix the gases as they leave the fire-box, causing better combustion. Heat is transmitted by radiation, convection, and conduction; it is, therefore, quite plain that while direct heating surface in the fire-box is subject to all three influences the surface in the flues of boilers can only be subject to one, viz., convection, and when the flue is covered with soot, which is so very often the case in brick-set boilers, the efficiency of the surface is very low." We also quote his paragraph on combustion. "I think this subject should be fully considered before designing a boiler of any description or criticising those already made. Heat is, you are probably all aware, caused by the chemical union of various elements, which in the case of burning coal and coke, consists principally of the oxygen of the atmosphere being mixed with the carbon and hydrogen (especially the latter, the heating power of hydrogen being three times greater than that of carbon) this affinity is greatly increased at a high temperature. As there is only one part of oxygen to four parts of nitrogen in the atmosphere, we see the necessity of introducing a large amount of air to ensure perfect combustion, in fact, providing that the air is sufficiently heated, I think it is almost impossible to introduce too much in a low pressure hot water boiler. Mr. H. J. Mills in his treatise on boilers puts the amount of air required to consume one ton of coal perfectly at 120,000 cubic feet. It will be seen from the foregoing remarks the reason for a thin fire giving a much better result than a thick one. As a rule it is safe to say that the smaller the fuel the thinner the fire should be, and the larger the fuel the thicker on account of the larger interstices in the use of the latter. It is a common practice to leave the fire-door open for a short time after firing to consume the smoke. This, of course, is wrong, for though you get a large supply of oxygen, yet as it is at a low temperature and does not therefore combine properly with the gases, the boiler is being cooled instead of heated, and in the case of wrought iron or steel it also proves injurious to the plates."

The details of a test made by Mr. Pearson will perhaps interest our readers. The boiler was a cast-iron horizontal sectional boiler 54 inches long by 22 inches by 18 inches (inside measurements); fire grate, 8 square feet; direct heating surface, 50 feet. Flues taken at half value estimated power (allowing 4 feet of 4-inch pipe per foot of direct surface), 2,050 feet of 4-inch pipe; actual, 1,950 feet. The boiler was worked to its full capacity during thirteen hours per day, and was banked up to burn slowly for the remaining eleven hours; fuel consisted of half slack and half gas coke. Fuel consumed equalled 30 cwt. per week of six days (as the fire was banked up during Sundays). This is a very favourable result, and could probably be considerably improved by substituting coal for slack.

Most of us have been troubled at some time with damp stoke holes, so we make no apology for giving this paragraph *in extenso*.

"Damp Boiler Holes.—These are often a source of considerable trouble to both heating engineers and their clients, and I think most of the trouble is caused by engineers trying to keep water out of the stoke holes built with flat sides and bottom by merely laying the bricks in cement or lining with Val de Travers, without considering the pressure. This is very considerable, for the total amount on a boiler house floor 15 feet by 10 feet by 5 feet deep, supposing the subsoil water to be level with the top of the brickwork, is 54,000lb. or nearly 25 tons. It is therefore quite apparent that this must be provided for. With small, medium-sized boilers the simplest and best way is to place the boiler in a wrought iron tank, which should be well tarred inside and out and paved with blue bricks. Where the boiler is very large there should

be an inverted arch built under the floor of the stoke hole and tied to the side walls, which should be at least 14 inches, and have an inch space left between the 4½-inch and 9-inch work, to be afterwards filled with Val de Travers. Even with this plan the workmanship and material must be of the best to ensure success."

## THE PURCHASE OF ARTIFICIAL MANURES.

(Continued from page 239.)

*The nitrogenous-phosphatic manures.*—The most important of these is dissolved bones, though bone-meal, fish-meal, &c., have their value for certain purposes. Dissolved bones lose in value through being damp and lumpy; they can, however, be bought as dry and almost as fine as superphosphate. They usually contain 32-34 per cent. of total phosphates (of which more than half should be soluble) and fully 3 per cent. of nitrogen. Bone-meal should be very fine and free from grease. Any particles one-tenth of an inch or upwards in size become available very slowly. It should hold about 50 per cent. of phosphates and 4 per cent. of nitrogen.

*Potash manures.*—Genuine kainit contains about 12½ per cent. potash, besides which it holds over 30 per cent. of common salt. Where, therefore, a farmer wants to use the latter substance he may find it to his advantage to employ this manure. Sulphate of potash is offered in various degrees of strength, containing from 25 per cent. to over 40 per cent. of potash. Muriate or chloride of potash often holds over 50 per cent. of potash. All potash manures are apt to be lumpy, and if they are stored long they may become so hard as to be almost unmanageable. Poor mechanical condition is here quite as undesirable as in the case of other manures. Potash manures are most important for root and leguminous crops, less so for grass and cereals. There are many well-authenticated instances of potash manures doing positive harm to meadows, though in other cases they have been used effectively. Whether they are wanted on any particular farm or not can only be determined by experiment.

### VALUATION OF ARTIFICIAL MANURES.

There are various methods of valuing artificial manures, of which that known as valuation by units is most employed by farmers and dealers. The general trend of prices is determined by market influences, and is largely beyond the farmer's control, but a reliable method of valuation enables him quickly and accurately to conclude which of several samples of the same class of manure is the cheapest. The following figures must be regarded merely as examples, prices fluctuating considerably from year to year, and in different parts of the country, owing to a variety of causes.

For the purposes of the valuation of artificial manures a unit may be taken as synonymous with 1 per cent. of the valuable substance in a manure. To find the value of a unit we divide the price of a ton by the percentage composition of the manure. Thus sulphate of ammonia containing 20 per cent. nitrogen, and costing £11 per ton, carriage paid, offers nitrogen at £11·20 = 11s. per unit. Or as 20 per cent. of nitrogen is equivalent to about 24½ per cent. of ammonia, the cost of a unit of ammonia is 9s. 1d. We can use one or other of these unit-values to enable us to determine which of several samples of sulphate of ammonia is the cheapest. Suppose that we are offered other two samples, the one guaranteed 18½ per cent. and the other 16 per cent. of nitrogen. The price per ton of the former, on the same basis, should be 18½ × 11s. = £10 3s. 6d., while that of the latter should be 16 × 11s. = £8 16s. Comparing these figures with the price actually demanded we are able at once to determine which of the three lots of manure is the cheapest. It may be mentioned that it would be rather exceptional to have the opportunity of obtaining sulphate of ammonia so poor in nitrogen as 16·18 per cent., but dirty samples do sometimes occur, and if the quotation

of a price, to include carriage, can be obtained, one can sometimes secure good value in a low class manure, provided the impurities are of a perfectly harmless character. The value of a unit of nitrogen in nitrate of soda is generally rather higher than it is in sulphate of ammonia, which means that farmers regard the former source of nitrogen as rather the more valuable.

When sulphate of ammonia is selling at about £1 per ton, carriage paid, nitrate of soda will usually be costing about £9. On a basis of 15½ per cent. of nitrogen, the value of a unit in the latter case works out at  $\frac{£9}{15.5} = 11s. 9d.$ , that is 9d. higher than in the case of sulphate of ammonia. If we use this unit to value sulphate of ammonia, we should get the value of a ton as 20 x 11s. 9d. = £11 15s., which is 15s. higher than this manure can usually be bought for when nitrate of soda is at £9 per ton. Now, it lies in the power of many farmers to secure this 15s. by depending on sulphate of ammonia rather than nitrate of soda where the conditions are specially suitable for the use of the former substance. When sulphate of ammonia costs more—per unit of nitrogen—than nitrate of soda, as occasionally happens, the latter manure is almost invariably to be preferred.

As a rule, organic nitrogenous manures are priced in the market at a much higher rate per unit than is the case with the two manures just looked at. The results of their use do not justify this position, for organic nitrogen will not produce so much increase as nitrogen from nitrate of soda or sulphate of ammonia. If we employ 11s. 9d. as the value of a unit of nitrogen in its most effective form, and apply it to the valuation of some organic manures, we should get some such results as these:—

Fish-meal, say 8 per cent. nitrogen x 11s. 9d. = £4 14s., together with an allowance of about £1 for phosphates, giving a total value of £5 14s. per ton. Some samples of fish-meal hold more and some less than 8 per cent. of nitrogen, in which case the value would rise or fall, though not quite proportionately, on account of the phosphates.

(To be continued.)

## NURSERY GARDENS.

### THE KING'S ACRE NURSERIES, LIMITED, HEREFORD.

DISTANT some two miles or more from the ancient cathedral town of Hereford are situated the nursery grounds of the King's Acre Nurseries, Limited. To many, perhaps, these would be more familiar under the name of Cranston's Nurseries, for as such they were known until the last few years; and a generation ago in the world of horticulture, and more especially in the domain of Rose culture, Cranston was a name to conjure with. Originally established in 1785 by John Cranston, these nurseries, which of late had become somewhat unfamiliar, were taken over three years ago by the King's Acre Nurseries, Limited, entirely a private concern, and they now are, as we shall hope to show later, fast developing into one of the most up-to-date of British nurseries. Towards such an end intelligent cultivation and management are greatly assisted by natural advantages, for as is well known, and as has often been proved by displays of fruit at provincial and metropolitan exhibitions, Hereford as a fruit-growing county is very hard to beat, whether the fruits are considered with respect to their size or quality. Besides having the advantage of suitable climatic conditions, these Hereford nurseries possess a soil as rich and good as one could wish for, and, to judge from what we saw, one that is eminently suited to the culture of fruit trees and Roses. But few nurseries are privileged to contain so

interesting a spot as do the ancient gardens under notice. On the lawn in front of King's Acre House stands a grand old Cedar, which records state was planted in 1790, although we should have guessed it to be much more ancient. Beneath this tree originated the idea of the

FORMATION OF THE NATIONAL ROSE SOCIETY, and the gentlemen to whom is due the honour of founding this excellent society were Mr. John Cranston, of the King's Acre Nurseries, Mr. William Paul, and Mr. George Davidson, the latter a then well-known local nurseryman. Near by and also well worthy of note is one of the most handsome specimens of the Weeping Ash in the country: the circumference of the ground covered by the spread of its branches is no less than 48 yards. The King's Acre Nurseries are about 100 acres in extent. Within the last two or three years many acres of fresh land have been acquired, and the resulting crops show in a most decided manner how fruit trees, Roses, &c., appreciate new soil. The stretches of Apple, Pear, Plum, and other fruit trees, one, two, and three years old, from the bud or graft, were

A PLEASURE TO SEE, uniformly vigorous, clean, and healthy. The same words may be justly used with reference to the fruit trees in the older parts of the nurseries. They are strong and straight stemmed, having evidently been well cared for as maidens. The cordon Apples trees in the accompanying illustration are representative specimens. The importance of staking fruit trees when quite young is apparently recognised: no amount of subsequent training will make a crooked stem perfectly straight, and, besides, a tree that is properly staked and cared for when young will be able to take care of itself in the course of a year or two. We were struck by the clean vigorous growth of the trained Apricot, Peach, and Cherry trees, and it could hardly be an exaggeration to say that one might travel the country through and not find a more excellent lot of young Black Currant bushes. The Black Currant mite, we were informed, is here unknown, and we can well believe this. Rarely also have we had an opportunity of seeing such a satisfactory stretch of small bush fruit trees, of which there are many acres.

Nor does the healthy growth of leaf and branch belie the state of the roots, as we had an opportunity of learning: a Pear tree dug up haphazard from amongst thousands of other fruit trees exactly similar had a splendid lot of fibrous roots. Such trees one could plant with every prospect of success. To give an idea of the extent of the nursery stock one may mention that no less than 86,000 Apples, Pears, Plums, Cherries, &c., were worked last season, in addition to many thousands of bush fruit trees, such as Gooseberries, Currants, &c. One point upon which the King's Acre Nurseries pride themselves is the cleanliness both of the ground and of the plants. Nor is this

CORDON APPLE TREES IN THE KING'S ACRE NURSERIES, HEREFORD.

assumption unwarranted, for weeds in most of the quarters are conspicuously absent, and

#### NO TRACE OF DISEASE

did we see upon the trees. So sincere is the determination to prevent the introduction and probable subsequent establishment of American blight in the nurseries, that many old fruit trees in the immediate vicinity have been cut down and burned.

Both picturesque and interesting are the three drives which traverse these nurseries; one is bordered on both sides by an excellent selection of young conifers, another by Tea

Roses (the Rose border, however, will shortly be superseded by a border of herbaceous plants), and the third, which is in course of formation, by specimen fruit trees. Hornbeam hedges, 5 feet or 6 feet high, divide the nurseries into sections (large or small, according to the plants to be grown within), and thus ensure protection from cold winds, so destructive and weakening to plants when they are young.

Second only in importance to the culture of fruit trees is that of Roses. About

#### 150,000 ROSE TREES

are worked every year, and that they comprise the best varieties of Teas, Hybrid Teas, Hybrid Perpetuals, Noisettes, Climbers, &c., it is almost needless to say. Many are specially grown for covering walls, pillars, pergolas, &c., though dwarfs, half-standards and standards are of course grown in much larger numbers. We were much interested in a plot of some 20,000 dwarf Roses growing on the fresh land that we previously mentioned as having been added to the nurseries. Many were on the Manetti and the Briar cutting stocks, and less upon the seedling Briar, for the former are found to be the most satisfactory. As an example of the astonishing vigour of the plants and their evident appreciation of the existing conditions, we would mention the fact that a good number of the buds that were inserted in August last had produced strong shoots 10 inches or 12 inches long, and some were bearing blooms that would not have been out of place upon an exhibition board.

#### FOREST AND ORNAMENTAL TREES

and shrubs cover a large acreage. Many are specially grown for park and avenue planting. The conifers are remarkable for their robust and sturdy habit and good colour. The first-mentioned characteristic undoubtedly is largely due to the fact that each plant is allowed plenty of room in which to develop. There is a branch nursery at Birch, some six miles from Hereford, where the soil, though it contains no peat, proves to be eminently suited to the culture of Rhododendrons, Azaleas, and allied things usually spoken of as American plants. The features of plant culture under glass are at once apparent. They are represented by

#### ROSES IN POTS, CLEMATIS, AND AMPELOPSIS.

We saw several thousands of pot Roses, many of the climbing varieties having made shoots from 12 feet to 15 feet long in one season; these plants, moreover, were quite clean and uniform. The Ampelopsis Veitchii in small pots deserve specially to be mentioned; one could not wish to see better plants, vigorous, clean, and well furnished with healthy foliage. Clematis in small pots are also an important and extensive item, several thousands, growing in small pots and plunged in ashes out of doors, have made excellent growth, and many are still in flower. Tuberous Begonias and Gloxinias are grown in considerable quantities, and by continued hybridising good strains have been obtained. A peep into the well-arranged fruit room to see how finely coloured Hereford-grown Apples are, even in this untoward season, terminated our inspection of a nursery that is destined undoubtedly to earn a well-merited reputation.

#### NOTES ON THE MELON.

MELONS belong to the family which embraces widely different kinds of fruits, and includes the Cucumber, the Gourd, and the Vegetable Marrow; but of all the family the Melon is far and away the most important, whether considered as an article of

luxury in this country or as an article of food in the country in which it is indigenous. The Cantaloupe Melon, which takes its name from a town so-called near Rome, is the variety most esteemed on the Continent, to where it was introduced from Armenia. Miller says that it grows in that part of Armenia which borders on Persia in such plenty that a horse-load is sold for a crown.

The flesh of this Melon when grown to perfection is delicious; it is rather dry, inclined to hardness, and not melting or juicy as compared to the Melon grown in England under glass. It is imported in large quantities, and, as it is sold cheaply, affords to our industrial population wholesome and pleasant food. The Melon may be grown in this country in summer in unheated glass frames, and so grown is of superior flavour to the imported fruits, but it is to be obtained at our shops at so low a price that its culture in this country under artificial conditions will never be undertaken to any extent.

The Water Melon is a fruit greatly appreciated in Egypt, China, and the East Indies, where it is cultivated to a great extent on account of its grateful coolness and delicious flavour. In some parts of Egypt whole districts are said to be covered with Water Melons. They are sown in the sand on the banks of rivers. The variety of the Melon known to English gardeners appears to be a native of Tartary, and, like many more of our exotic fruits, is supposed to have been introduced into Britain from Italy. Gough states that Melons were common in England as early as the time of Edward III., but were entirely lost, as also was the Cucumber, during the Wars of the Roses. Miller voices a complaint of very long standing when he says that "in this country there are too many Melons produced of no value by those who supply the market, and who, in endeavouring to increase their size, render the fruits of no value."

That the complaint has existed from that time until now in a more or less acute form must, I am afraid, be admitted, but let us hope that the indictment pronounced against the Melon in his time is not warranted at the present day. As a fruit grown in British gardens the Melon may not claim to be in the front rank of importance as compared with some of our other more cherished fruits, yet no good dessert in summer is considered complete without its refreshing and welcome presence, and no committee of a summer show of any account would think of issuing a schedule without offering prizes for this popular summer fruit, and certainly no gardener is deserving the name who has not endeavoured, according to his opportunities, to excel in its cultivation.

Any structure that is sufficiently well heated will grow Melons satisfactorily under intelligent supervision, but for very early crops lean-to houses well heated are the best, and these should be facing due south. For summer crops no doubt span-roofed houses are the best, and they should be built with ends facing south and north, so that the plants will have full advantage of the morning, afternoon, and evening sunlight, and not the full force of the sun at the hottest time of the day.

I do not advocate large houses for Melons, for one reason because they succeed better in rather small ones, and for another that they can be more economically grown there, for, naturally, less fuel for heating purposes is required. As regards bottom heat for the borders, I prefer this to be furnished by leaves and straw litter mixed up in a sufficient quantity to make a bed 2 feet thick when well trodden down. This will afford a gentle and sufficient heat for three or four months until the crop is ripe. It used to be the custom years ago, and I am afraid it is now to a certain extent, to provide large, wide, and deep beds to accommodate the materials thought to be necessary for the successful culture of the Melon. This practice I need scarcely say entailed much waste and needless expense, for the Melon needs but little soil to grow in, as is evidenced by the heavy and excellent crops often produced by plants growing in comparatively small pots.

The size of bed 1 would advise if fermenting materials are used should be 3½ feet deep and 2 feet wide, allowing a little more than 2 feet for the fermenting materials, and rather less than 1 foot in depth for the soil. If hot water pipes are used a bed 2 feet deep by 2 feet wide will be large enough. The best compost for the Melon plant is turf cut from old pasture land, and if the land is inclined to be marly or of a strong loamy texture so much the better. The turf should be cut 4 inches deep with the grass intact. It is often recommended that with the loam should be mixed a certain quantity of organic manure in preparing the compost for Melons, but this, in my opinion, is a mistake, as of all materials loam alone is the best.

A. P. H.

#### MELONS IN FRAMES.

In a season like the present sunless one it is well to note which varieties prove a success in frames without the aid of artificial heat of any description. Our frames are standing on cold clay facing the south-east. Small hillocks of turf loam with a liberal amount of wood ashes formed the compost in which the Melons were planted, and this was made very firm. For several weeks after planting we had comparatively little sun, and the nights were very cold, consequently the plants, although looking healthy, made slow progress. They were planted out the first week in June, and since the beginning of September we have been cutting good Melons of excellent quality. I was at first rather doubtful about the flavour (owing to the absence of sun), although the aroma was very pronounced, but my employers put my mind at ease by telling me the Melons were delicious. The varieties grown were: Hero of Lockinge, Sutton's AI, Ringleader, and Perfection. The method of training the plants is much the same as when growing in houses, except that the laterals are more thinly disposed, an important fact often neglected by amateurs. Watering and ventilation must also be carefully attended to; in dull cold weather it is better to err on the dry side, giving copious supplies of water in hot sunny weather.

Cam.

J. G.

#### THE INDOOR GARDEN.

#### CELOSIAS.

**W**HEN well grown these decorative subjects are much admired on account of their bright and graceful plumes. I find, however, that some amateurs fail to obtain the best results, generally because of the attacks of various insects, which the plants are rather subject to if grown in a dry atmosphere. We find about the first week in May a good time to sow the seed; there is no advantage in sowing earlier as the seed quickly germinates, and in early spring the seedlings are apt to be crowded and soon get spoilt. When young they require a moist atmosphere to grow in, plying the syringe to the under side of the leaves twice daily. A suitable compost to pot them in consists of loam one half, leaf soil, dry cow manure, and sand. The pots should be well drained, 5-inch ones being large enough for ordinary purposes. When the plumes begin to show a conservatory is an admirable place for them; associate them if possible with green and white foliated plants, for a very pleasing effect is then gained.

A good method of keeping red spider in check is to sponge well the under side of the leaves occasionally with soapy water. Thrips and aphid can be dealt with by fumigation. It is well known that Celosias make excellent bedding plants, but they are equally effective when grown in pots. Most nurserymen supply good strains, the Drumlanrig and dwarf forms of Messrs. Veitch being excellent in every way.

**FRITILLARIES IN THE GRASS.**

IN THE GARDEN of September 20, page 195, an exhaustive article is given upon naturalising flowers in the grass. We thought the accompanying illustration of Fritillaries, so well established in grass, would interest our readers. As many are well aware the Fritillary is a native meadow flower, and in many a moist Oxfordshire meadow makes spreading colonies, whilst it is also a good flower for the garden. We notice that at Kew small beds of it upon grass are filled with it. We are indebted to Messrs. Richard Smith and Co., Worcester, for the illustration. Naturalising flowers in the grass is becoming a popular phase of English gardening, and it is certainly a very beautiful way of showing many of the most charming bulbs flowers to best advantage. But only those things that are at home in the grass should be put there. We have seen strange results from growing things more adapted to the border.

there are some good things amongst them. Coming to our best eighteen, first we have, for crimson,

*Mrs. Carter Page*, now well known, the fault of which is that it flowers so scantily, but in other respects is good; and next

*Mrs. Winstanley*.—Here we have a recent and sterling introduction. The plants are very dwarf and sturdy, yet they produce numbers of large finely formed blooms from early in the season till late, the colour being a bright orange-scarlet. Perfect flower stem.

*Mrs. Edward Marley* is very fine indeed. The flower is large, refined, and of perfect form; the plants are strong and the flower stem stiff.

*Mrs. J. J. Crowe* may also safely be grown as another yellow, but we much prefer *Mrs. Mawley* in every way. Coming to dark flowers, *Uncle Tom* and *Aunt Chloe*, both by the same raiser, are still the best. Uncle Tom is well known, and Aunt Chloe, introduced last spring, is a very pretty flower, though a trifle small. The plants are sturdy, and the flower is carried

at base, with white tips. Some of the petals have a band of red down the sides, the blooms quite pendent; and

*Richard Dean*, dark red, heavily tipped with white, too deep at first, but is now opening favourably. The blooms are carried on very long stems, the colour being most striking.

*Alpha*, the new fancy Cactus, though rather heavy in form, is a first-rate bloomer, and quite successful as an all-round Cactus Dahlia. It was by no means rare in some of the best prize stands at the large shows. It is of good size, and continuous in flowering.

*J. W. Wilkinson* must of course be included, but it now needs little description, and

*Lyric*, yellow at base, with scarlet at the points, good when caught just right, but it has a nasty way of going bad at the back long before it is in its prime; also

*Lesta*, rosy pink, rather heavy in form, but indispensable by reason of its colour.

Coming to white, well, a good one is still

FRITILLARIES NATURALISED IN GRASS.

**THE BEST CACTUS DAHLIAS.**

So numerous are Cactus Dahlias becoming, and the output of new ones each year is so abundant, that to read about the varieties in a catalogue is confusing. Yet when the varieties come to be sifted down there are not many very fine ones, from an exhibitor's point of view, but at the same time only those which are good in other respects are mentioned, unless special allusion is made to some defect, such as poor habit, pendent growth, &c. In giving the names and brief descriptions of the best eighteen, the various colours are given, as in several cases other good varieties might be mentioned of similar hue, but the idea is to name a representative collection, such as an up-to-date grower might rely upon as the best obtainable. Here we may mention that no new varieties certificate this autumn are included, as it is impossible to say what these will turn out when grown another year, but to judge from what we saw of them at the shows

quite upright. Our bushes of this are now a picture.

In orange and salmon shades there are always plenty to choose from, and the following are the best:—

*Major Tuppenny*.—Needs no comment.

*Lottie Dean*.—Yellow in centre, shading to amber-buff, fine petals, slightly incurved at the points.

*Florence*.—Yellowish orange, abundant bloomer, of wiry growth, and should be better known.

*Goldfinch*.—Tall, rather late, but very beautiful flower, both in form and colour. Of bicolors we had quite a show last spring, the following three being the best:—

*Gabriel*.—Very pretty indeed, each with white-tipped petals incurving so abruptly as to form an elbow. Just where the red portion of the floret begins the blooms when fully out are quite balls of petal; the habit of the plant is robust, and it flowers freely.

*Columbia*.—A straight petalled variety, crimson

wanted. Probably one of the new whites seen this autumn for the first time will at last supply the long-felt want, but at present

*Lord Roberts* is the best. It is usually in splendid form early in the season, and has long finely-twisted petals, and somewhat pendent although wiry growth.

*P. W. Tullock*, a large incurved flower, salmon-red, shaded with purple, is good with us, and was shown well on several occasions. It has exceedingly wiry stems and flowers freely.

*J. Weir Fife* is still good. This variety varies from deep blackish purple to quite a magenta colour, oftentimes coming striped with both, and at other times half and half. It has large flowers.

We have now named twenty of the finest, and yet feel there are one or two more that should be added. Of these

*Britannia* is one of the best still, and other good ones are *Bessie Mitchell*, *Floradora*, *Pretoria*, *Ajax*, and *Magnificent*.

DAHLIA.

## NOTES FROM SCOTLAND.

## THE KING'S VISIT TO TYNINGHAME.

ON the 10th inst. the King paid a flying visit to the Earl of Haddington's seat at Tynningham, passing on his journey from North Berwick the famous Binning Woods, the earliest attempt at systematic tree planting in Scotland. Though so late in the season both gardens were quite gay with flowering plants, nothing excelling the masses of Tritoma Uvaria for brilliance. "Bedding-out" for autumn effect is still continued in the garden near the house, but on somewhat different lines from that generally followed, and though there is much brightness, nothing gaudy or tawdry is permitted. In the walled garden, to which His Majesty walked, the main borders are occupied by a great variety of plants suitable to its somewhat formal design. These are mostly arranged in large groups, and in some cases the borders are in one colour. The long arched Apple walk, with its trees covered with fruit, greatly attracted His Majesty's attention, and he also examined with interest a designed garden in box laid out inside the larger one. The examples of old garden statuary and the iron gateways were also closely examined, but time did not permit for an extended view of all the garden treasures, an Oak tree, which His Majesty planted, occupying the last minutes of his stay. An early eighteenth Beech avenue was passed through by the King on his way from Whittingham, the Right Hon. A. J. Balfour, M.P., having driven His Majesty through

the grounds there on his way from North Berwick.

## A SEVERE FROST.

about the beginning of the month destroyed flowers and tender subjects generally in mid-Scotland. As a proof of the lateness of the season such early Apples as Keswick Codlin are not fit to gather in the middle of the month. Fortunately both Apples and Pears have developed in a remarkable way during the present month, and winter vegetables have made great progress.

## MR. DOWNE,

Edinburgh, had the honour of supplying a purple Sycamore for the King to plant in North Berwick. Mr. W. MacKinnon superintended operations.

R. P. BROTHERSTON.

## SOCIETIES.

## BRISTOL AND DISTRICT GARDENERS' ASSOCIATION.

THE opening meeting of this association was held at St. John's Rooms, Redland, on the 9th inst., under the chairmanship of Mr. E. Binfield, Old Sneyd Park. On this occasion Mr. Brooks, of Messrs. Garaway's Nursery, Clifton, gave an interesting lecture on the great fruit show of the Royal Horticultural Society held at the Crystal Palace, London. He dealt with the numerous exhibits of former years, and, comparing with those of the present season, showed the effects such a summer we have just experienced must have on the fruit supply of the British Isles. He emphasised the fact that gardeners would find it an excellent object-lesson to visit these shows at intervals, thereby gaining a knowledge of fruit grown in different counties and under different conditions. He argued that gentlemen would find it to their advantage to send their gardeners to inspect the exhibits at this the finest fruit show of the British Isles, where they would see the best

quality, and return home with the full intention to grow their fruit equal to that they had seen at the show of shows. Comparing the fruit of this to the fruit of last season, the lecturer remarked on the absence of many of our leading exhibitors, which proved how disastrous our sunless summer had been to fruit crops, and where 4,000 dishes of fruit had been shown in former years, only 1,000 were on the tables this. Mr. Brooks also gave some very useful information as to the packing of fruit, a fact which we are very apt to forget, mentioning the mode adopted by leading exhibitors, which should be of service to the Bristol gardeners. A good discussion followed Mr. Brooks's lecture, and he was cordially thanked for his trouble in putting together such an interesting paper.

The prizes for the evening were for two bunches each of black and white Grapes. For black, the first went to Mr. N. C. Dobson (gardener, Mr. Thoday); Mr. Francis Taggart, F.L.S. (gardener, Mr. Binfield), securing first for Muscat of Alexandria; while Mr. W. A. F. Powell (gardener, Mr. Raikes) was an excellent second for Golden Champion. Lady Cave (gardener, Mr. Poole, F.R.H.S.) obtained a certificate of merit for a collection of ornamental Gourds, the judges also awarding one to Mr. J. M. Kitley, Littleover, Derby, for three bunches black Grapes, notwithstanding they were very much spoilt in transit.

## AMATEUR GARDENERS' (LIVERPOOL BRANCH) ASSOCIATION.

THE monthly meeting was held in the Common Hall, Hackin's Key, Mr. Ellison in the chair. The prize winners of the exhibits were Mrs. Stevenson, and Messrs. Thomas, Muir, Robbins, and Dodd. Mr. R. Pinnington was introduced as the lecturer, selecting "Seasonable Notes" as his subject, which included preparing, planting, and pruning of fruit trees with reference to the best methods of exhibiting. Lily culture was the next point for consideration, early plants being advised in a good compost of loam, rough sand, and leaf-mould, plunging the pots up to their rims in ashes under frames, which avoided the danger of over watering, which is so detrimental to the bulbs. Mr. Ardran proposed that a hearty vote of thanks should be accorded to Mr. Pinnington for his lucid and admirable address. This was carried with applause.

# THE GARDEN

No. 1614.—VOL. LXII.]

[OCTOBER 25, 1902]

## THE MIXED BORDER IN ENGLISH GARDENS.

**A**S this is a subject of much interest, and alluded to on page 284, we think a few general remarks will be helpful to our readers.

Some kind of border where there is a mixture of hardy flowers is to be found in every garden. Sometimes it is merely a place where all sorts of plants find a home without regard to effect or any intentional arrangement, but more often, and especially when it is in the more ornamental part of the garden, a good effect is desired, and some advice about its arrangement may be of use.

It is not altogether an easy matter to keep a mixed border well furnished throughout the flowery months of the year, and to avoid unsightly gaps, but there are ways of doing it, and even beginners should not be afraid of facing this fact, and of thinking out ways and contriving methods so as to have as few empty places as may be. There are some common-sense considerations that will be a guide to the choice of plants to use. The first and most obvious is that the plant must be in itself handsome and somewhat showy. The next, and one of the most important, is that it should remain a good while in flower. Plants that are in flower a few days only and then are done are of little use in the mixed border, unless their foliage is unusually handsome and persistent, in which case this is so valuable a quality that it may redeem the plant.

The choice of kinds being decided on, the way in which they are arranged then becomes the matter of chief importance. It seems a natural arrangement to use the creeping and short-growing plants in front and the next in stature behind them, and the tall ones at the back. This is obviously a good general rule, but if not varied with judicious exceptions the result will be very monotonous. Now and then some of the tall backward groups should break forward. Think of the way in which the lateral spurs of a mountain chain descend into the valley or plain. They all do come down to the level, but in how varied and beautiful a way! Think of this and then think of the dull and ugly slope of a slate roof, and then think of your border and apply the lesson.

Then try and get hold of some definite scheme of colouring, in order to get richness and brilliancy with dignity. It saves much trouble and puzzling at planting time to have a regular

scheme of simple progression of colour from end to end, so that if you have a yellow-flowered thing to plant you put it in the yellow place and so on. In no way can you get so much real power of colour, by which is meant strength, richness, and brilliancy, as by beginning very quietly at the ends of the border with cool-coloured bluish foliage and flowers of tender colouring, white, pale blue, and palest sulphur-yellow, and even with these palest pink; beginning quite *piano*, then feeling the way to full, and from that to strong yellows; then by a gradual *crescendo* to rich orange, and from that to the *forte* and *fortissimo* of scarlets and strong blood-crimsons, and then again descending in the scale of strength to the pale and tender colouring.

In other parts of the garden you may have incidents of brilliant contrast, which are especially desirable in the case of strong blue flowers; but in the mixed border the way of having the rich and brilliant harmony approached by more delicate colouring can scarcely be improved upon, and so only can the vice of garish vulgarity be avoided.

Plants of the same colouring are intergrouped, so that the red group, whether early or late, is always a red group, and so on throughout. There are ways of filling gaps by training plants down to fill the spaces. For this use, Everlasting Peas, tall perennial Sunflowers, and Rudbeckias and Dahlias are especially accommodating.

Nothing is so destructive of good effect in the mixed border as the old unthinking mixed up way. Plants of the same kind, instead of being dotted at equal intervals, should be grouped together, each group dying away into the neighbouring group, or if there is only one plant of a kind there is no harm in its being one alone if only it is in its right place.

Of course there are other ways of arranging the details of a mixed border, and many devices that may be used to enhance its effect at the different seasons, but these suggestions will be a good basis of operation to anyone who is without experience and desires general instruction.

---

## THE ROYAL HORTICULTURAL SOCIETY.

### DONATION FROM THE KING.

We feel sure all well-wishers of the Royal Horticultural Society and of the new hall will be pleased to know that His Majesty the King has given one hundred guineas towards the

building fund. The following letter recently appeared in the *Times*:—

"Balmoral Castle, September 30, 1902.

"My dear Holford,—The King has been much pleased to hear of the intention of the Royal Horticultural Society to commemorate its centenary in 1904 by the erection of a new horticultural hall for the use of the society.

"I showed the King Sir Trevor Lawrence's letter, and His Majesty commanded me to tell you that he perfectly remembered having addressed the society in 1890, as Sir Trevor states, and you are to tell him from the King that the words His Majesty spoke in 1890 he repeats now, if possible, with a stronger feeling than ever, not only of the desirability but of the actual necessity of such a building as it is proposed by the society to erect.

"Sir Trevor and the society, the King commands me to say, have His Majesty's best wishes in their undertaking, and as a small donation from His Majesty, by way of showing the interest he takes in the Royal Horticultural Society, I am now commanded to forward you a cheque for one hundred guineas towards the fund which is being raised for the new buildings.

"Believe me, my dear Holford,  
"Very truly yours,

"D. M. PROBYN.

"To Captain George Holford, C.V.O., C.I.E."

I am to explain that as long ago as 1890 the society had in contemplation the provision of accommodation for its fortnightly shows and office work. In that year His Majesty was graciously pleased to open the society's great show in the gardens of the Inner Temple, and in doing so the King used these words: "I sincerely hope that your labours to obtain a hall of your own may be successful, for I feel sure that it would be of the greatest use and advantage."

Since 1890 the Royal Horticultural Society (founded in 1804) has very largely increased in numbers and influence until it has become the universally recognised head of the scientific and practical horticulture of the United Kingdom, both amateur and professional, connected with which are flourishing industries of ever-growing importance. To prove that this is so I need only mention that the society has now more than 6,000 Fellows, of whom 1,000 have been elected this year.

The single aim and object of the society is to guide and direct the art and science of gardening in all its developments and to popularise the most innocent and fascinating of pursuits.

The financial position of the society is in all respects sound.

A circular has been prepared and is about to be issued for the information of the Fellows of the society and others interested, containing plans, elevations, and particulars of the new hall, which will be built on the estate of the

Ecclesiastical Commissioners facing Vincent Square, S.W., and looking south. A sum of about £19,000 has already been promised towards the cost of the new buildings, estimated at from £35,000 to £40,000. The treasurer of the society, Mr. J. Gurney Fowler, will gratefully acknowledge any contributions.

I am, Sir, your obedient servant,  
WILLIAM WILKS, M.A., Secretary.

Royal Horticultural Society,  
117, Victoria Street, Westminster.

At the meeting of the Royal Horticultural Society on Tuesday last it was announced by the secretary, the Rev. W. Wilks, that in addition to the letter and donation from His Majesty, H.R.H. the Prince of Wales had also written to Captain Holford, a member of the council, expressing his sympathy with the scheme for building a new horticultural hall and enclosing a cheque for fifty guineas. The secretary also informed the meeting that Mr. Leopold de Rothschild had contributed 500 guineas to the fund. This, said the secretary, shows that the project has the sympathy of the highest in the land, and it is to be hoped that every Fellow will follow the good example that has been set. Those who can afford a lot should give a lot, and those who can afford a guinea should not forget to give their guinea, then when everything is complete all may feel they have helped.

Tuesday last was a record day in the history of the society, for the number of Fellows now elected since the beginning of this year is no less than 1,005. Never before in the history of this society have 1,000 members been elected in one year. It is very gratifying, said the Rev. W. Wilks, to find the Royal Horticultural Society so much appreciated.

In the absence of the president (Sir Trevor Lawrence, Bart.), who had hoped to be present but was obliged to attend a meeting in connexion with the King's Hospital Fund, Mr. Harry J. Veitch said he had been requested by the council of the Royal Horticultural Society to present a Victoria Medal of Honour in Horticulture to Dr. Massee, Mr. J. T. Bennett-Poë, M.A., and Mr. Henry Cannell. Mr. Veitch first explained to the meeting how this medal was instituted in the Diamond Jubilee year of the reign of the late Queen Victoria, by permission of Her Majesty, for bestowal upon distinguished horticulturists. The number of those holding the medal can never exceed sixty-three, and the present medals were being given because of vacancies caused by the regretted deaths of former recipients.

Dr. Massee, who first received the medal, is the leading authority upon plant diseases, said Mr. Veitch, and in the herbarium of the Royal Gardens, Kew, has made cryptogamic botany his special study. Dr. Massee had also given lectures and much valuable help to the Chiswick students.

Mr. Bennett-Poë, who next was called, is well known to many, said the chairman. He is to be congratulated upon the energy and patience he has shown in cultivating and bringing to notice many beautiful plants that are difficult to grow and little known. Mr. Bennett-Poë had also been a most valuable member of council.

Mr. Henry Cannell, the third recipient of the medal, had done much for practical horticulture, said Mr. Veitch. It was he who first improved the Dahlia, of which we have now so many beautiful varieties. This was just one instance of Mr. Cannell's valuable work among the flowers.

## EDITOR'S TABLE.

### SEEDLING DOUBLE AND SEMI-DOUBLE WELSH POPPY.

Mr. J. McWalters, The Mall, Armagh, writes: "An autumn gathering of blooms from seedlings of the double and semi-double Welsh Poppy (*Meconopsis cambrica* fl.-pl.). These were gathered on October 13, and if the weather continues favourable I expect the plants will continue in bloom for some time."

[A very interesting contribution to our table: the flowers were as described, and of warm orange and yellow colourings, double without coarseness. A good garden flower.]

### CIMICIFUGA JAPONICA.

Mr. T. B. Field, Ashwellthorpe Hall Gardens, Norwich, writes: "I am sending for your table flowers of *Cimicifuga japonica*. This is one of the most beautiful of our autumn flowers. It is of very easy culture and luxuriates in a deep rich soil. A place should be found for it in every garden however small. Its erect divided leaves and drooping racemes of white flowers make it admired by all who see it."

[A beautiful and neglected plant. We hope those who have not got it in their gardens will make a good note of it. The flower racemes are of purest white, and have an agreeably wholesome fragrance.]

### A NEW GREENHOUSE RHODODENDRON.

Messrs. Fisher, Son, and Sibray, Limited, Handsworth Nurseries, near Sheffield, send us flowers of a lovely new greenhouse Rhododendron named Duchess of Portland. They are of such a rich pink colour and so freely produced that this variety should quickly become popular. Messrs. Fisher, Son, and Sibray say that they have been cutting flowers from medium-sized plants for the past month, and they give promise of continuing to bloom for some time yet. This greenhouse Rhododendron was raised by Messrs. Fisher, Son, and Sibray, and we imagine it will prove to be one of the best autumn-flowering plants of its class.

## TREES AND SHRUBS.

### RHODODENDRONS AND THE SEASON.

On the whole, the weather this year has been favourable for the growth of Rhododendrons, though without the fine, dry time experienced during September very few flower-buds would have formed. The plants grew very freely throughout July and August, the rain during the latter month especially causing the growths to lengthen freely, but without showing any signs of bud except on a few early-flowering sorts, which usually complete their growth in good time. The drier weather of September, however, combined with cold nights (the glass showing from 1° to 4° of frost on several occasions) had the effect of checking growth without injury and promoting the formation of good flower-buds. On the drier ground the set of buds is fairly good, though one or two sorts have not set as well as one could wish, Lady E. Cathecart being the worst, but young plants of this sort rarely set many flower-buds except in a very favourable season, though large plants 6 feet and upwards in height are usually budded on every shoot. As a large plant this is one of the best Rhododendrons known. On the lower and damper ground the plants are much better set with buds than was expected, considering the season, though there are many that have failed to form flower-buds, while others have partly made a bud and then commenced to grow again, which

spoils any chance of their carrying bloom next year. Some sorts—notably Kate Waterer—have formed flower-buds on this second growth, and which, when in bloom, will be rather smaller in size of truss but of good shape and colour. The young stock of Rhododendrons worked last spring were put out during the beginning of August and have done remarkably well, the losses being very slight. The wet weather of August was exactly what they required, and at the present time the whole of them, somewhat over 20,000, are in the very best condition and looking very hard and sturdy. On the whole, the past season has been favourable to Rhododendrons, and, though the chances of the formation of many flower-buds seemed small at one time, yet the dry autumn has caused a good set of bud, though, generally, it is less than it was last year.

*Bayshot, Surrey.*

J. CLARK.

## STILL OCTOBER.

"The time of the silence  
Of birds is upon us;  
Stately and splendid  
The summer passes."

NOWADAYS one is often told half grumbly that the seasons have shifted, but is this true? Looking carefully into it shall we not find that the summers and winters of these days come and go pretty much as they always did? Are they not a figment of the imagination, those good old-fashioned Christmases, all icicles and robins, May days of Hawthorn and the Maypole, summers that were all sunshine, winters all skating days and snow. Who originated these legendary tales? It is always the passing generation that speaks about them to the present, and we who now are young will soon be doing the same thing to the next. We shall seize upon the facts we best remember; we shall misplace and mix them up, saying the present years are vastly inferior to the old, and that even the seasons are not so well balanced as they used to be. And we shall say that the seasons have shifted. We shall declare that Midsummer day once *really* came in the middle of summer, and that Christmas, instead of arriving in late autumn as it does now, was truly a winter festival, and we shall go on being to the last degree surprised and delighted when, as in 1902, summer lingers on, more lovely every day till "still October" is with us telling us all beauty must change and pass.

October is one of the months that is maligned. In spite of storms that sometimes rend her, October's face is fair and her skies as blue as June, and notwithstanding Mr. Millais's picture, we do not allow that she is always chill. "I will wrap me in mists, white and fine," says my lady October. So she does, and her days are shortened, but her mist-wreaths are only for the nights and mornings. No sooner is the sun up than how mellow may be its beams and then how rich, October's robe of gold and crimson.

But the rarer and more excellent charm of the tenth month is its stillness. Many a scene of peaceful beauty is brought us by October. Here is a slow-moving barge, lazily passing onwards between the banks of a canal; a woman with her noonday cooking-pots, faint blue smoke up-curling; a man, his pipe alight, lying prone; trees, banks, Bracken, and the flat-brimmed barge itself, bemirrored in the stream, perfect in the water as in the sunny haze, where float the water-flies, or maybe it is the utter quietude of the reddening woods that draws us, where

"Scarlet hosts of Maple trees—  
The torches of the year—  
Burn low, and beauty grows too deadly fair  
For man to bear."

In October the world is resting. There is no chill as of death, only the warm and tender flush of sleep. And much more often is October still than chill. Gone is the zest and fervour of the growing months. The sap sinks, the dormouse hides, the squirrel is asleep and dreaming, but Nature is yet alive. In the garden there bloom October flowers as gold and crimson as the sunsets, the Pampas-plumes have put off till now the pushing of their feathery brushes through their fine and delicate tubes. The garden is as quiet as the woods. We can hear a pin—I mean an Acorn-drop, or a Chestnut as it falls through the overhanging bough, dead leaves and red leaves flutter softly down upon the grass.

All the migrants have departed: no willow-warblers now ring merry peals from out the Oak trees. Day after day fresh gaps are found among the garden folk, both flowered and feathered. The ranks are closing up, and this makes all the steadfast friends that stay with us so much more precious. More cosy, too, and more endeared and intimate, just as it is in a house-party that has been thinned by guests that have gone away. How more than ever tame is now the dark-eyed robin, who pipes for us his prettiest tune, and how soft the blackbird's boxwood fluting, as he and his little wife in rusty black flutter in and out of the shrubberies, only pretending to be shy, among the pink-eyed purple Phloxes, the tall Anemones, the sweet Tobacco-plants, and the pale frail flowers of the Evening Primrose.

The earth now radiates the warmth she has been storing up in the long light days of spring and summer. We need not wonder at such kindly heat. The mistake we made was in looking for the warmth too soon. Almanacs are so misleading. They tell us spring is here, just as we want our furs and fires the most, and prate of summer as soon as days grow long. As well might we expect the kettle to boil the moment the faggots are crackling, or the room to be fit to live in directly the fire is lit, as to feel any benefit from sun-heat before it has had time to penetrate and warm the ground.

Our mistakes about the seasons have cut two ways. Early disappointments are forgotten in the unlooked-for sweetness of October. We need not mind having been behindhand with the almanacs and the stars while we enjoy St. Luke's summer in the usual way, gathering the autumn Roses as pink and perfect as if made of sea-shells, plucking the juicy Blackberries and listening to the gossip of the birds. Every one of the seasons has its sweetness:

"For myself I would choose  
The soft mists of October;  
Her habit and veil I would choose,  
And her rich thoughts more sober."

F. A. B.

## KEW NOTES.

### INTERESTING PLANTS IN FLOWER.

#### Temperate House.

*LONICERA ETRUSCA*, Rhododendron (Java), various hybrids, and *Tricyrtis hirta*.

#### Palm House.

*Cribium careyanum*, *C. erubescens* var. *minus*, *Hymenocallis eucharidifolia*, and *Medinilla javanensis*.

#### Water Lily House.

*Clerodendron disparifolium*, *Hedychium coronarium*, and *H. spicatum*.

#### Orchid Houses.

*Acineta Barkeri*, *Angraecum distichum*, *Bulbo-*

*phyllum careyanum*, *B. Dearei*, *B. rufinum*, *Catasetum christyanum*, *C. fimbriatum*, *Cattleya aclandiae*, *C. bowringiana*, *C. labiate* var. *aurea*, *Coeleogyne lagena*, *Cymbidium longifolium*, *Cypripedium Charlesworthii*, *Dendrobium Phalaenopsis*, *D. sanguinolentum* var., *D. secundum*, *Epidendrum Armstrongii*, *Eulophia pulchra*, *Houlebia brocklehurstiana*, *Ionopsis paniculata*, *Listrostachys Monteirei*, *Lycaste xylophora*, *Maxillaria grandiflora*, *Miltonia candida*, *M. spectabilis* var. *moreliana*, *Mormodes Buccinator*, *M. pardina*, *Neolentharia gracilis*, *Odontoglossum andersonianum*, *O. grande*, *O. Hallii*, *O. odoratum*, *Oncidium crispum*, *O. Forbesii*, *O. Papilio*, *O. varicosum*, *Platycylinis cobbiana*, *Pleurothallis pulchella*, *Polystachya luteola*, *P. rufinula*, *P. tessellata*, *Rodriguezia fragrans*, *Selenipedium longifolium*, *S. Schlimgii*, *Stenoglottis fimbriata*, *Vanda coerulea*, and *Zygopetalum cochlearia*.

#### T Range.

*Aristolochia clypeata*, *Callipsyche aurantiaca*, *Clerodendron splendens*, *Daedalanthus parvus*, *Dipladenia eximia*, *Erica conspicua*, *E. spicata*, *E. tubiflora*, *Hippocratea aulicum*, *Ipomoea rubrocerulea*, *Nerine* (various species and varieties), *Passiflora amabilis*, *Pelargonium citriodorum*, *P. fragrans*, *P. Schottii*, *Thunbergia grandiflora*, and *Zephyranthes gracilifolia*.

#### Succulent House.

*Crassula rubricunda*, *Dyckia brevifolia*, *Senecio sub-scandens*, and *Solanandra grandiflora*.

#### Greenhouse.

Among other things the following are conspicuous: *Chrysanthemums* in variety, *Eupatorium odoratum*, *Lilium sulphureum*, *Peristrophe speciosa*, *Tibouchina macrantha*, *Salvia azurea*, and *S. splendens* var. *grandiflora*.

#### Herbaceous Plants.

*Cortaderia argentea*, *Crocus asturicus* and varieties *atropurpureus* and *azureus*, *C. cancellatus* and varieties, *C. hadriaticus* var. *chrysobelonius*, *C. iridiiflorus*, *C. longiflorus*, *C. pulchellus*, *Funkia lancifolia* var. *tardiflora*, *Kniphofia corallina*, *K. sarcimentosa*, *Liriope spicata*, and *Zizania aquatica*.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

October 28.—Croydon Chrysanthemum Show (two days).

October 29.—Kent County Chrysanthemum Show at Lewisham (two days); Highgate Chrysanthemum Show (three days).

October 30.—Penarth Chrysanthemum Show.

October 31.—Finchley and Leyton Chrysanthemum Shows (each two days).

November 1.—Battersea and Derby Chrysanthemum Shows (each two days).

November 4.—National Chrysanthemum Society's Exhibition, Royal Aquarium (three days); Royal Horticultural Society's committees meet; Southampton and West of England Chrysanthemum Shows (each two days).

November 5.—Hanley, Margate, Northampton, Cardiff, Cambridge, Hereford, Sevenoaks, Truro, Southend-on-Sea, Halifax, and Ascot Chrysanthemum Shows (each two days).

**Fruit show at Cork.**—An exhibition of Irish-grown fruit and fruit products, organised under the auspices of the Department of Agriculture and Technical Instruction for Ireland, was held recently in the Concert Hall of the Cork Exhibition. Though the show was confined, as far as its competitive sections were concerned, to Irish fruit producers, there were also exhibits from some prominent English firms. Mr. William Baylor Hartland, Patrick Street, Cork, was given a special award for an excellent display of Irish-grown fruit. The following papers were read at the conference:—"Apple Growing for Profit," by Mr. F. W. Moore; "Prospects of Fruit Growing

in Connaught," by Mr. John Galvin; "The Progress of Fruit Growing generally in Ireland, and some of the Grievances of Irish Fruit Growers," by Mr. W. R. Orr; "The Marketing of Irish Fruit," by Mr. W. L. Cole; "Methods of Dealing with Second Grade Fruits and Vegetables, and an appreciation of the value of same as items of Dietary," by Mr. James Harper.

**United Horticultural Benefit and Provident Society.**—The sixteenth annual dinner of this society, which was held last week, and of which a full account appears elsewhere, was a most successful one. The society now has £20,000 invested and almost 1,000 benefit members, besides between seventy and eighty honorary members. The committee are most anxious to increase the number of members to 1,000 and 100 respectively, so all those interested should take note of this and give their help. Mr. Arthur W. Sutton, who presided at the dinner, very kindly promised to insert a paragraph in the forthcoming catalogues issued by his firm drawing attention to the advantages of this society, and he trusted that other firms would see their way to do the same.

**Royal Caledonian Horticultural Society.**—The date of the spring show for 1903 has been altered to May 20 and 21. Besides the many classes for plants, cut flowers, and fruit, the schedule contains information respecting the competition open to under gardeners only, for a plan, drawn to scale, for laying out a piece of ground about three acres in extent, as shown on a given sketch plan. All plans for this competition must be in the hands of the secretary, Mr. P. Murray Thomson, 5, York Place, Edinburgh, not later than April 1 next. A special notice in the schedule states that the council having resolved to do away with all the competitive classes in the nurserymen's section will grant awards to meritorious exhibits, and they invite the hearty co-operation of nurserymen and florists.

**Chrysanthemum show at Alexandra Palace.**—An important event in the history of the Highgate and District Chrysanthemum Society will be the holding of its annual exhibition in the Alexandra Palace on Wednesday, Thursday, and Friday next. Those best competent to judge feel confident the society has done the proper thing in arranging for the use of the Central Hall of the Palace for this season's display. There are very few better halls in the country for horticultural exhibitions than the great hall of Alexandra Palace, and in view of the fact that there is a most liberal schedule of prizes, in which classes for all types of the Chrysanthemum are represented, the display on this occasion should be a very good one. Promises of support have already been received from trade and other growers, and as there are a few classes in which the prizes are very tempting, the combined efforts should create an exhibition of a brilliant character, and one which will be regarded as a red-letter day in the history of the society. Not the least important attractions of the show will be the groups of artistic design and the decorative exhibits, for which the Highgate Society has always been justly famous. Mr. W. E. Boyce, 20, Holmesdale Road, Highgate, N., is the secretary, and is always willing to give all possible information.—D. B. C.

**Lily Henryi.**—Having seen glowing accounts of this Lily in trade catalogues and elsewhere, I confess to being somewhat disappointed. I have seen it well grown too. The flowers are comparatively small, and appear even smaller by reason of their height from the ground—usually 6 feet—of an undecided yellow colour and quite scentless. *L. speciosum*, which it somewhat resembles, is far more beautiful, easily grown, and is about one-fifth of the price.—W. P. [We think our correspondent must have seen this beautiful Lily at a disadvantage. It is one of the most vigorous of the whole family, perhaps not so showy as many others, but its apricot colouring is fresh and distinct. We have seen it in many gardens and always with pleasure. Dr. Henry, after whom it is named, writes about it in this week's issue, page 284.—Ed.]

**The season's flowers.**—Crimson Roses are the most striking denizens of the borders. Here and there belated *Lilium speciosum* show brilliant colouring, and *Pelargoniums*, zonal and Ivy-leaved, brighten the shortening days. But the effect of one boldly-designed bed attracts much notice; it is comprised of *Salvia splendens*, alternating with groups of *Hedychium gardnerianum* and bordered with a broad band of *Ageratum*. The *Hedychiums* are splendid in their yellow and scarlet spikes of feathery flowers, and contrast well with the richly-coloured *Salvias*. Dahlias are blooming freely, and the blue-blossomed shrub *Caryopteris Mastacanthus* tones down the golden *Harpaliums*. The tiny Roses (Elfin Roses) sown in February and blooming in June are radiant gems; the second year plants are perfect in miniature form and varied tints.—C. R.

**Is Mme. Jules Grolez Rose scentless?**—Messrs. Frank Cant and Co., Braiswick Rose Gardens, Colchester, write: "Mme. Jules Grolez is strong and sweetly perfumed, and I am glad to see that there are some readers who appreciate this lovely Rose."

I can fully endorse the editorial remarks at page 240 relative to the fragrance of this lovely Rose. In fact, I alluded to its fragrance in a short paragraph concerning the variety as far back as July 30, 1898. Mr. Sawyer in his excellent little work "Rhodologia," which is about the odour of the Rose, says at page 12: "Cut Roses placed in a vase diffuse their fragrance more powerfully than when growing on the plant;" and also: "It is a well-known fact that at different times in the day an individual flower will emit a different perfume." The fragrance of the Rose is a subject worthy of more attention than it has hitherto received. Why cannot the framers of prize schedules establish a class for the most fragrant Roses? But perhaps the judging of the same would be a difficulty. Unquestionably, individuals vary considerably in their ability to appreciate fragrance in flowers. Mr. Sawyer says in the work quoted (page 9) that "the organs of the sense of smell can be trained to the appreciation of perfumes, especially by young persons, as the palate can be trained for business purposes to the tasting of the flavours of wines, tea, or coffee." Some individuals would go so far as to bar all Roses from their garden that are devoid of fragrance, and as a guide to such that are most fragrant we seem to require an authoritative pronouncement. Cannot someone who has leisure take up this matter and divide the varieties now grown into, say, three groups: (1) most fragrant; (2) moderately fragrant; (3) quite devoid of fragrance?—PHILWELL.

As differences in soil and atmospheric conditions probably exercise an influence on the perfume given off by some varieties of Roses, you may be interested in my experience. Since reading the remarks in THE GARDEN of October 18 I have on three different occasions carefully examined several blooms of this variety and found them all sweet-scented. The perfume is not so strong as in the case of La France, but is more refined than that of many Hybrid Teas, and in this respect I think it nearly approaches to many of the pure Teas. I may add that I found the young blooms gave off a stronger perfume than the fully expanded ones. There is no doubt but that this is one of our very best Roses, and I hope that other growers will be able to confirm your verdict as to its scent.—OSMOND G. OPEN, Hillside, West Bergholt, Colchester.

**Notes from Ireland.**—During the past week, on the occasion of a visit to the charming gardens of Sir Jocelyn Gore Booth, Bart., at the foot of Ben Bulbin (so dear to Irish botanists), and

extending to the shores of the Atlantic on the peninsula of Raughley, on the western coast of Ireland, between Sligo and Bundoran, what impressed me most were the masses of blue Hydrangeas which were to be seen at every turn through this magnificent place. Fringing the avenues, forming thickets in the parks, and as an undergrowth in the forests, blue Hydrangeas were everywhere. To those whose sole conception of this charming flowering shrub consists in the contemplation of a stunted specimen in a tub or an occasional isolated bush in the grass, my attempt to convey even a faint idea of the superlative beauty of acres of gigantic specimens densely covered with their enormous trusses of bright blue flowers will, I fear, be futile. The Hydrangeas at Lissadell are certainly worth going a thousand miles to see. The peculiarity of the Hydrangeas in this place (apart from their wonderful size and luxuriance of growth) is the almost entire absence of any tinge of pink in the flowers. With the exception of a group of bushes near the gardener's

Irish horticulturists. The report of this great show and conference will form the subject of next week's notes.—T. SHAW.

**The White Rock Cress (*Arabis albida*) on a wall.**—I send you a photograph—amongst others—of *Arabis albida*, growing at Crosby Farm, Crosby-on-Eden, near Carlisle, which was photographed on May 21 of this year. It was just past its best when I took the photograph, but the result was very much better than I anticipated. This Rock Cress has been growing for some years at the foot of this hedge, and, I understand, was much admired by persons passing along the main road, which is on the other side of the gate. The Rock Cress has an easterly aspect, the roots are situated at the foot of the hedge, and the long trailing stems of the plants hang down over a brick facing to the hedge. No particular attention, I believe, is given to the culture of this bright charming spring flower, which seems to have made itself at home, and every year is a beautiful sight.—R. CARRUTHERS, Eden Grove, Carlisle.

THE WHITE ROCK CRESS (*ARABIS ALBIDA*) ON A LOW STONE WALL.

residence—beautifully situated on the sea shore—I did not notice a suspicion of pink among the flowers. On the contrary, every shade of blue, from pale cerulean in the woods to deep blue in the open was represented. I may mention that many of the individual bushes were over 8 feet high and 10 feet or 12 feet in diameter, and carried several thousands of enormous trusses of flowers. We are now almost on the threshold of the Chrysanthemum season, and though we would fain believe that summer, or at least autumn, has not yet left us, we are actively interested in the two great events of the winter season—the Royal Horticultural Society of Ireland's show at Ballsbridge and the still greater function which attracts Irish Chrysanthemum growers to the northern capital, both of which events occur in the first fortnight of November. The great show of Irish-grown fruit, which the Department of Agriculture have organised—as a fitting consummation of their herculean work in the cause of the development of Irish industry—at the Cork Exhibition is the all-absorbing topic amongst

**Blue Crocuses.**—Among "Items of Interest" in the *Daily Mail* of the 29th inst., I read "Blue Crocuses are to be seen blooming at Leamington Spa," as though this were a phenomenon. It would appear by this that the autumn Crocus (*C. speciosus*), which I suppose the writer saw, is not grown as commonly as it should be.—W. P. [We quite agree with our correspondent. This beautiful Crocus is not grown nearly so much as it deserves.—ED.]

**The Gardeners' Royal Benevolent Institution. — Proposed Liverpool Auxiliary.**—In the report of the meeting held in the City Hall on March 12, 1902, for the purpose of extending the knowledge and aiding the funds of the above institution, which the committee have the pleasure to record as an unqualified success, we notice the following paragraph:—"The committee desire to recommend that an Auxiliary of the Gardeners' Royal Benevolent Institution should be formed in Liverpool, and that a general meeting of those interested be called in October for carrying out the necessary details."

**November sowing of Sweet Peas.**

I tried sowing these in various winter months in pots kept in the unheated glass house, to be planted out for early flowering. I found November was the best month to sow the seed, and the plants kept in flower much longer than those forced by fire-heat. From seed sown on November 10 the plants were 1 inch high by December 7; shifted into 8½-inch pots on January 30 and staked; planted in the border, two pots to each group, April 24; in flower May 3 until middle of August. The year before seed sown the same date in November flowered from May 25 until the end of October, but then the plants were fed with liquid manure.—WINIFRED SPURLING.

**Late Peach Thames Bank.**—I was glad to note that at the recent Palace show of hardy British fruits there was a very good dish of the above variety. I was rather amused to find it described as a new introduction, as I have grown it for many years. It is rarely seen; why, I do not know, as I consider it one of the best of the late Peaches in the yellow-fleshed section. I am aware the yellow varieties in many cases do not compare with others—they lack flavour; still Thames Bank is one of the best, and its lateness makes it more valuable. This variety was raised within sight of the Thames by a good fruit grower in his day, Mr. Rust (at Broom House, Fulham), and he grew it well for many years. The flesh is deep orange and the skin also, and the fruits rather more oblong in shape than round. The flesh is tender and juicy, and well flavoured for a yellow Peach. Its season is late September, and it keeps good for some time after being gathered from the trees. In size it is larger than most Peaches, and in this respect it resembles Late Admirable, but is superior to it in flavour.—S. H. B.

**Black Bryony.**—The black Bryony grows in the Surrey lanes with trails of berries 2 feet or 3 feet long, and if these are picked when ripening vary from emerald green to scarlet, and make lovely decoration for the room. After several weeks they become dead ripe, and if laid just as they are in the ground, say, under a western fence, covered with a few inches of soil, they will come up freely the following year. The next year, when the small plants have died down, they should have 6 inches or more of soil put on them, as at that stage they suffer if frost gets at them. They bear berries about the third year. It is difficult to take up plants out of the hedges as the tubers are so deep down, and besides are so soft they easily rot when transplanted. It is also necessary to have a lot of plants together, as they are diceous, male and female blooms being on different plants, so that only if grown together do female plants bear berries.—J. R. D., *Surrey*.

**Colonial training for women.**—The Horticultural College, Swanley, has recently opened a colonial training branch, where women will receive preparation for colonial life, with special regard to horticulture, dairy work, and other outdoor occupations. The syllabus for the autumn term includes horticulture, domestic economy, jam making and bottling of fruit, instruction in native South African languages, fruit packing, milking, &c. The half term begins on November 10. The Colonial syllabus is arranged in conjunction with the British Women's Emigration Association. The Hon. Sir John Cockburn, K.C.M.G., is now a director of the Swanley College, and his name also appears upon the Colonial branch committee.

**New Strawberry St. Antoine de Padoue.**—The introduction a few years ago of the perpetual Strawberries is an immense gain to the private grower, who with a little attention to cultural details can now have ripe Strawberries well into the autumn. I have never seen better results with regard to crop than this season, but I fear on some heavy soils and damp places, if the plants are at all thick, difficulties have occurred in ripening the fruit owing to lack of sunshine. This note is written to point out the value of this new fruit, and though, from a market point of view, St. Antoine de Padoue is not large enough it must certainly become a standard variety for late supplies. One of the best points about this

perpetual race is their simple culture. When given a fairly rich not too heavy soil they make splendid growth. The earlier introduction, St. Joseph, is one of the parents, the other being the Royal Sovereign; but the fruit does not greatly resemble the last-named other than that the plant is a stronger grower and the fruits larger, of a bright red colour, with good flavour, even at this late season, and nearly round in shape. By planting these varieties to follow the summer fruiters there is no break in the supply if different positions are given to the plants. For latest supplies the first blossom that shows is removed. I have seen splendid crops on plants that fruited early, made new runners, and on these gave a later crop.—G. WYTHES.

**Neglect of British Ferns.**—The varieties of British Ferns are very numerous, and so varied and beautiful are they in growth and formation that they should be more largely grown, though I am aware there are many excellent collections grown out of doors, also of magnificent specimens rivalling the exotics, grown simply in a cool house. Whilst framers of schedules only turn their attention to the heat-loving species we are not likely to see British Ferns take their rightful position. How many small growers would take up their culture had they the encouragement from horticultural societies to do so, and one is glad to notice this step being taken up in several directions. Summer schedules will soon be formed, and the framers of such might do worse than include a class, and so benefit a considerable number of enthusiasts who have neither the time nor command of heat required for exotic species. I feel sure that many of your readers will support me in my plea. If so, I shall be pleased to name some good varieties suitable for pot culture.—A. B.

**Peach Marquis of Downshire.**—This is a valuable late Peach, not only for its crop but also for its flavour. I fear under this name it is not so well known as it should be. It is an old but good variety that should not be overlooked. It was raised many years ago by Mr. J. Standish, of Ascot, and sent out as Royal Ascot. Why it was called the Marquis of Downshire I am unable to say, but fruit growers are well aware that a good fruit of any kind frequently gets several names in different localities. I consider this variety of better quality than several of the late Peaches, such as Barrington, Late Admirable, and others. The fruits are large—at any rate above medium size—with a light red cheek, mottled and a darker red where exposed to the sun, flesh tender, very juicy, and sweet. It is a freestone. The flowers are large and produced later than some kinds. As regards cropping it is one of the best and a very free grower, its season being late in September. Doubtless on account of its late flowering the crop is superior, as in some seasons when others fail this crops freely. This variety is not in many fruit grower's catalogues.—S. H. B.

**Pear Grossé Calebasse.**—Fruit tree planting will soon be in full operation, and in almost all gardens varieties not hitherto grown will now be included. Stewing Pears in many large establishments play such an important part that they cannot well be overlooked, and from all appearances will be still more in demand. Cadillac and Uvedale's St. Germain are probably the best known in this section, but I want to impress upon those not acquainted with this Pear to include it. Grown as an espalier it is perfect, making abundance of fruit buds and a short-jointed growth, the fruit often weighing 1½ lb. and upwards. Coming into use in November it is highly appreciated, but care should be taken not to let it get over ripe or the centre becomes black. The colour of the fruit being a dark brown is often misleading in this respect.—A. B.

**Calceolaria Burbidgei.**—This plant was raised in the Trinity College Botanical Gardens, at Dublin, in 1879-80, and was the result of crossing the flowers of *C. fuchsiaeifolia* (= *C. deflexa*) with pollen of *C. Pavoni*. In habit of growth and in leafage the hybrid resembles its pollen parent, but the flowers are more like those of *C. fuchsiaeifolia* or *C. amplexicaulis*. The hybrid roots freely from cuttings, and is a rampant grower, especially

as planted out in the bed or border of a cool greenhouse, and it is peculiar amongst Calceolarias in flowering during the autumn, winter, and spring months, better than during the summer season. It was originally described in THE GARDEN, Vol. XIX., page 59, by Mr. W. E. Gumbleton, under the name of *C. hybrida* Burbidgei. In THE GARDEN, Vol. XX., page 422, Mr. T. Smith, of Newry, in alluding to this hybrid, remarks that all my seedling hybrids were alike in habit and leafage, whereas a batch raised by himself at Newry from the same parents, contained all sorts of intermediates between the parents in habit and leafage. Unfortunately, an accident happened and all the Newry hybrids were lost or died before they flowered. *C. Burbidgei* was illustrated by a coloured plate in THE GARDEN, and is generally to be seen in bloom during the autumn and winter season in the greenhouse (old No. 4) at Kew.—F. W. BURBIDGE.

**THE WALL GARDEN.****THE WALL GARDEN IN OCTOBER.**

**Q**UITE a number of attractive plants are either still in bloom or are flowering for the second time, especially in the West of England. Nor are those still blooming confined to the larger or more robust kinds like Red Valerian or Sedum spectabile, which were mentioned in previous notes, and are still very bright, but quite a variety of small perennial wall plants have not yet finished flowering.

*Linaria pallida* is among the neatest of wall plants. In the rock garden or border, where it can spread as it pleases, it is apt to become a nuisance, and often comes up in places where it is not wanted, but in the joints of a wall, where its spreading powers are limited, it is an excellent thing, and its lilac flowers with yellow throat are most attractive.

*Ethionema grandiflorum* is now flowering for the second time. It is true the flowers are not as large as those which appeared in May or June, but anything in the shape of flowers is welcome in October, and these pink flowers contrasted against glaucous foliage are certainly striking.

*Corydalis lutea*, as well as its cogener *Corydalis alba*, are still flowering, and better wall plants it would be difficult to find. They are satisfied with the often scanty nourishment obtainable from narrow joints in a wall, and their flowering season seems only quite over when winter sets in.

*Achillea tomentosa* with its bright yellow corymbs of flowers is also blooming a second time. It is not quite so satisfactory a plant for the joints of a wall as the Fumitory mentioned above, but its proper place is the top of a wall. In such a position it will thrive admirably, while

*Tunica Saxifraga* will do for either side or bottom. Its loose pendent shoots and its pale pink flowers make it a desirable plant for wall gardening.

*Echereria farina* is a good wall plant only in the southern or western counties, where there would be little to fear from frost. It is not at all hardy in the Midlands or in the North. Its chief attraction lies in its almost snowy white, thick, fleshy leaves. For a hot dry sunny position it is a desirable plant where the climate is warm enough.

*Polygonum vaccinifolium* has already been mentioned in previous notes, but it is still in bloom. Its cogener *Polygonum Brunonis* is much more rampant in growth. It is blooming for the second time now. The leaves are 6 inches to 8 inches in length, while those of *P. vaccinifolium* are less than an inch, and while the latter species is seen at its best when hanging down from the top of a wall, *P. Brunonis* is best at the bottom. Its pink flowers are attractive, but it must certainly have plenty of room.

*Calandrinia umbellata*, with its brilliant magenta

flowers, is again flowering a second time, though its proper flowering season is generally July. It is an excellent wall plant for a sunny position. In some localities it is only biennial, whilst in others it will last for many years.

*Arenaria grandiflora* has larger flowers and blooms later than its companion *A. montana*. I noticed it in several gardens in Cornwall blooming for the second time, and its pure white flowers are always welcome. It is not quite so pendent in its mode of growth as *Arenaria montana*, and is therefore not quite so elegant a plant for the top of a wall, but planted on the face of the wall between the joints it is generally satisfactory.

*Sempervivum Laggeri* I also noticed in full bloom in October. It is larger in all its parts than the more generally known Cobweb Houseleek (*S. arachnoideum*), and is an excellent plant for a dry wall with very narrow joints. It is most accommodating and will grow even in mortar joints. In fact if it is divided and its rosettes of foliage are inserted, even without any soil, among the chinks of the stones it will generally thrive where most other things would fail.

*Androsace Leichtlini*, or, as it is sometimes called, *Androsace lanuginosa oculata*, with its white flowers with crimson eye and its silky grey foliage, is an excellent wall plant. It will grow in quite narrow joints, provided there is at least a little gritty soil between the stones. Its flowering capacity seems to extend over a longer period than that of the better known lilac species, *A. lanuginosa*, for while the latter has passed out of bloom some time ago *A. Leichtlini* is still quite an attraction.

*Cullirhoe involucrata*, with its large brilliant purple flowers, is still blooming, and makes a good plant for a sunny position on the top of a wall, where its prostrate shoots would display their blossoms to greater advantage. Its individual flowers have a white centre and are quite the size of half-a-crown or even larger.

*Sedums* generally are more attractive on account of their foliage this month than for their flowers, though several are still in bloom, among them being *Sedum spectabile*, *S. Telephium*, *S. sibiricum*, *S. pruinatum*, and *S. spurium*, all with red or reddish flowers.

*Campanula isophylla* and *C. isophylla alba* are not sufficiently hardy for wall gardens, except in warm sheltered situations, but in Cornwall they are still blooming now and make a glorious display.

*Elaeis*, Exeter.

F. W. MEYER.

## THE HAMMOCK UNDER THE OAKS - IV.

### BEAUTY OF PHLOXES.

LATE in July our Phloxes are at their best. We have tried many varieties and grown them in many combinations. Perhaps nothing is prettier than a good stretch of one variety, such as *Auguste Rivière*, one of the finest French sorts lately introduced. This has large trusses of bloom, and is a rich carmine, a very distinct and beautiful shade. Some Phloxes are as scarlet as Geraniums. Coquelicot is one of these, and makes a brilliant bed on the grass of the lawn. We have to find a place remote from all other red flowers for the crimson and amaranth shades which do not harmonise with the other sorts. Some of the newer kinds are so brilliant that we cannot dispense with them. Toned down by free admixture with the white kinds they look very well; they are good carrying colours, and really very effective.

A separate border contains some lovely pink and light carmine sorts, such as *Adonis*, *Pantheon*, *Ornament*, and *Captain Wilhelmy*. The pure white sorts and the white with rose-coloured eyes, such as *Amazone* and *Henri Murger*, can be planted almost anywhere as they do not jar with other flowers. If my choice were limited to eighteen varieties, I would choose Coquelicot, *Flambeau*, *Caran d'Ache*, *Auguste Rivière*, *Coccinea*, *Pantheon*, *Adonis*, *Captain Wilhelmy*, *William Robinson*, *Ornament*, *Eclaireur*, *Le Vengeur*, *Oberon*, *General Chanzy*, *Henri Murger*, *Miss Lingard*, *Amazone*, and *Matador*.

From the hammock under the Oaks I can see all these and many more. On my left, in front of the wild garden, are the lake and crimson sorts, such as *Le Vengeur*, which is a tall kind with splendid glowing blossoms of rich amaranthine red. *Matador* is next, and is a lighter shade of the same red. Here, too, is the new *Eclaireur*, which is crimson with darker centre and a ring of rosy white around the eye. It is rather dwarf, with very large heads of bloom. In this bed also is an old but good variety called *Lothair*, a light carmine colour, and, for relief to the bright-coloured groups, there are plantings of the tall pure white *Amazone*, the early-flowering rather dwarf *Miss Lingard*, also white, and *Richard Wallace*, white with rosy eye, another old variety. On my right is a long stretch of border in front of some old Cherry trees, which give it partial shade, planted with *Coquelicot* and *Flambeau*, two sorts that are both scarlet and very much alike.

If I turn my head I can see behind the hammock on the other side of the path leading to it the pink and vermillion-coloured sorts, which we think the most beautiful of all. *Auguste Rivière*, *Ornament*, *Adonis*, *Pantheon*, *Coccinea*, and *Captain Wilhelmy* are among the best of these. We like to have a specialty for every month of the flowering season, and the *Phlox* is the speciality for July. One would not think that we could succeed as well as we do with them in this dry garden on top of a hill. Even *Miss Jekyll* complains that her *Phloxes* dry up and show brown stalks and withered lower leaves. I always think the climate of England an ideal one for flowers. It is so moist and temperate compared to our parching summers with their torrid heat. Nevertheless, and while we fail with very many lovely flowers that the humblest cottager in England grows to perfection, we do succeed with *Phloxes*. What they seem to want is heat, moisture, rich, not sandy soil, and partial shade. This year we have had what the farmers call a "good growing season," with much more rain than usual, and not very many days of torrid heat. Yet the 17th of this month was intensely hot. All day long the wind blew from the south-west, a parching wind like a sirocco. That is the wind we dread the most—the wind that brings heat. At six o'clock p.m., the thermometer stood at 96° Fahrenheit; next morning it was 95° at nine o'clock; but before long a thunderstorm cooled the air, and now it is comparatively pleasant at 80°.

To return to the *Phloxes*. I think the secret of our success with them is that they are planted in soil made rich with plenty of wood's earth mixed with well-rotted cow manure. These beds are deeply dug and kept well stirred and well watered when necessary. All of them are in partial shade, without being too near the larger trees of the grove. We also mulch these beds in dry weather.

Whatever else we may have to neglect we always pay due attention to our *Phloxes*, because they are the garden's pride. I used to experiment with a great many plants more or less adapted to the conditions here; but now I am more ambitious to grow a few plants to perfection than to have a very large variety of flowers. Each month some one conspicuous plant is made the feature of the garden for that month. It is the queen of the month, around which the other flowers group like ladies of the Court. Almost all of the *Phloxes* I have mentioned are called autumn-bloomers; but with us they begin to flower late in June and continue until blighted by frost. I do not mean that all our varieties bloom for such a long period. Most of them do not flower well until the middle of July. *Miss Lingard*, a low-growing sort, flowers in June, and is the first of all; *Henri Murger* follows in a week or ten days, and then the others in twos and threes, until all are in flower at once.

### OTHER BEAUTIFUL PERENNIALS.

Besides *Phloxes* there are a great many other perennials now in bloom. The path to the hammock skirts a rough bank for some 20 feet, and this bank we have, in humble imitation of a bank at Kew, planted with *Yuccas*, interspersed

with grasses and plants with sword-shaped leaves. Here, besides *Yuccas* in several species, are *Hemerocallis*, *Antheriums*, *Asphodels*, *Hyacinthus candidans*, *Lyme*, and *Pampas Grasses*, and at the top *Arundo donax* makes quite an imposing display.

Just now the only plant in bloom on this bank is some clumps of a tall *Hemerocallis*, which I obtained under the name of *H. Sieboldii*. Whether this is its right name I cannot tell, as there is so much confusion among dealers in naming *Hemerocallis*. It is a valuable species, blooming long after *H. flava* is over. The plants throw up many stalks, 2½ feet to 3 feet in height, bearing trumpet-shaped blossoms, tubular at the base. The colour is a clear lemon yellow, and they have no fragrance. There is always a deficiency of blue flowers in my garden. Perhaps it is for this reason that I prize so much the few blossoms of this colour that I have. There are a few *Campanulas*, *Platycodon*, and *Delphiniums*, but these do not make much display. *Cornflowers* we always have with us, but *Cornflowers* are not effective in the mass; their colour does not carry well. They are useful to put in vases and pretty at close quarters, but at a little distance their effect is lost. Nature is sparing in her use of blue as if it were not after all an earthly but a celestial colour. There is something very appealing about some flowers of this cerulean hue. The *Forget-me-not* is a sentimental little plant that everybody loves, while if it were yellow or pink it would not be prized at all. The faint blue of *Innocence*, whose other name is *Quaker Lady* (*Houstonia caerulea*), is enough to make one weep, not mawkish tears, but tears of gladness that any flower can express so much purity and peace. Who has ever seen a little bank by a stream in a green meadow covered with fragile *Bluets* without feeling better and happier for the sight?

The tininess of some flowers makes us love them all the more. When Tennyson speaks of

"The little Speedwell's darling blue,

I think he must have meant the little wild *Veronica* that is one of our earliest wild flowers, and that has minute pearly blue flowers delicately veined with azure.

If we had a blue flower as small and fragile as *Innocence* and with as delicate fragrance as trailing *Arbutus* what a favourite it would be! But, strange to say, blue flowers are never fragrant, are they? I cannot think of any really blue flowers that are so. It seems as if Nature had done enough for them in giving them the colour of the sky, and reserves her gifts of fragrance for less favoured blossoms. Violets are not blue, though they are called so. Many purple, violet, or mauve-coloured blossoms, like *Heliotrope*, for instance, are exceedingly fragrant, but I cannot think of one fragrant blue flower. After breakfast this morning I counted my *Hollyhocks*, and was pleased to find that I have thirty kinds. Some are single and some double. I have the species called the *Fig-leaved Hollyhock* and some of the new crimped *Allegheny* kinds. My *Hollyhocks* are in twenty shades of colour, ranging from white to almost black. *Hollyhocks* assume nearly all the colours that *Roses* do; every colour except blue may be found among them. However, I must qualify this statement, for I have never found a *Hollyhock* of the colour of the Austrian Copper Briar. I have quantities of them in the orchard along the fence. A hedge of *Hollyhocks* makes a fine screen to shut off the Corn-patch at the top of the orchard hill. They do not suffer from the *Hollyhock* disease, and they increase and multiply and hybridise themselves at their pleasure. Some of the hybrids between the common sorts and the *Fig-leaved* are very pretty, in odd shades of salmon-pink and pale tawny yellows. The *Fig-leaved* has lemon-coloured blossoms. Is there such a thing as an orange-coloured *Hollyhock*? I wonder? They are handsome but not aristocratic flowers, and remind me of cottage maids. They never look better than when associated with homely surroundings, as the kitchen yard or to screen outbuildings. We have a great many of them in front of the carriage-house, but these are not going to bloom this year. They were all eaten

by the cows, who have developed an extraordinary appetite for Hollyhocks. The cows cannot get to the orchard, so all the Hollyhocks there are still unchewed, but those by the carriage-house are quite devoured down to the ground, so that we have been drinking our Hollyhocks in milk.

DANSE DANDRIDGE.

Rose Brake, West Virginia, U.S.A.

## NOTES ON HARDY PLANTS

### VERATRUM VIRIDE.

**T**HIS plant (shown in the accompanying illustration) was introduced from North America in 1742, but unfortunately is now rarely met with outside botanic gardens, which is possibly owing to the fact that its flowers are not showy, being of a light green. It is, however, a truly handsome plant, and is seen to advantage skirting the front of the shrubbery or along a woodland walk. It does

for these flowers before forming a representative collection of the autumn and winter-flowering forms. Some of these are scarce and too expensive for planting by the dozen or hundred, but there are others, again, which are cheap enough to be purchased in such numbers as will form a clump at a moderate price. Such are *C. speciosus*, *C. zonatus*, and *C. pulchellus*, one of the prettiest of the Crocuses which bloom in autumn. One cannot repeat too often that the Crocuses are not to be confounded with the Colchicums, which custom has recognised as the Autumn Crocus. The true Crocuses are far more refined and beautiful, and have ranges of colour not to be found among the Meadow Saffrons. In *C. pulchellus*, for instance, we have a small flower with the most pleasing pearl-blue colouring, quite a distinct tone from *C. zonatus* or *C. speciosus*, and as fine form as either. A few years ago it was quite an expensive Crocus, but now nine or ten can be bought for what was once the price of one. Like many other autumn flowers, it does not produce its leaves until after the flowers have gone, and it is thus all the better for being carpeted with something which will be green in autumn and is yet a surface rooter. A *Sedum*,

me, I was pleased to come across a white-flowered variety in a nursery a short time ago. Unfortunately, the stock was not large enough for its being put into the market, but with such a good grower as this plant is there ought not to be much difficulty in its propagation for sale ere long. *C. g. hirsuta alba* hardly needs any description, as it is simply a perfectly white variety of the type, and resembling it in every particular save that of colour. One will be only too glad to have this plant when it is for sale.

### VERONICA PARVIFLORA.

THIS New Zealand Veronica is one of the species which are not sufficiently well known in gardens, for many of these Veronicas are hardier than most persons imagine, especially if they are planted where they do not get the sun too early in the morning. *V. parviflora* is one which has proved thoroughly hardy in my garden, though I have seen it a little the worse after a bad spring. I have never lost a plant from the weather, and it has been grown here for at least ten or twelve years. It forms a pretty bush, about 3½ feet high, though I can hardly say what height it would reach if left unpruned; it is pretty with its narrow light green foliage. Yet it owes most of its beauty to its flowers, and not the least of its value in the garden is due to its long blooming. It is in flower for months as a rule. I have several good bushes, and these have been, and still are, delightful with their little spikes of white flowers. It must be said, however, that *V. parviflora* has rather a reputation for tenderness, but I originally received it from an inland Scottish garden, where it was hardy on a stiffish soil and in a low and cold situation. The greater number of my plants are self-sown seedlings, and these come up very freely about the rockeries on which the older plants are grown.

S. ARNOTT.

Carsethorn, by Dumfries, N.B.

### ANDROSACE LANUGINOSA.

I REGARD this as the best of all the Androsaces. No Androsace can be grown successfully year after year and flower month by month as will this one; indeed, the plant seems only to require the absence of frost from our midst to render it quite perpetual flowering. I have some young plants in the cutting boxes that have flowered twice this year already, and the now forward points produced since the latest flowering have apparently flower-trusses still. It is plants of this class that I

regard as first-class in every way, and therefore plants for everybody to grow abundantly. Yet with all its good qualities it is not grown as one would expect, when we remember that few things are so well suited for furnishing rocky slopes or even carpeting beds of dwarf shrubs and in other ways. A capital place for it is a rocky bank. Certainly nothing could be more beautiful than its hoary leafage. Then again in blossom, where there is a patch worthy the name there is the ever-changing character of the flowers to catch the eye at every turn. The flowers vary from lilac of a pinkish hue to a creamy colour, which may be heightened or otherwise by soil or position. To see it in perfection a bank or slope should be clothed with it, or at least a patch 8 feet or 10 feet across, as I saw in a garden in early summer. All the plant requires is a good depth of loam freely intermingled with sand and old mortar refuse. If given this, and the drainage is also secure, the plant will be benefited by much more moisture than can be with impunity given to a large number of the species, and what is more to the point is the fact that overhead moisture is not harmful. In the hottest soils and positions the plantation may be in a rather sheltered place, but north of Birmingham,

VERATRUM VIRIDE IN THE PHYSIC GARDEN, CHELSEA.

not mind shade if this is not too dense. The lower leaves are broad and massive, beautifully recurved and plaited, and on this account alone the plant is worth growing. When well established the branched racemes of flowers are borne in profusion, and reach a height of 4 feet to 5 feet. The flowers show polygamy to a marked degree; in some cases bisexual flowers are found on certain branches, and on others unisexual, and it not infrequently happens that entire plants bear male flowers only. Although the plant enjoys a rich loamy soil, it is not fastidious in this respect. Propagation may be effected by means of seeds or division of the rhizomes; but since Veratrums are rather impatient of root disturbance seeds are preferable, being best sown as soon as ripe owing to their soon losing vitality.

Chelsea Physic Garden.

W. HALES.

### CROCUS PULCELLUS.

THERE is a steady increase in the number of those who grow collections of Crocus species, but, like everything else, one needs to acquire an enthusiasm

such as *S. Lydium*, or a Saxifrage of mossy habit, is as good as anything, but the drawback of the Saxifrage is that it forms a harbour for slugs, which are fond of the flowers of *Crocus pulchellus* and other autumn-blooming Crocuses. This Crocus is a native of the North of Asia.

### CAMPANULA GARGANICA HIRSUTA ALBA.

CAMPANULAS of dwarf habit are always appreciated by the alpine lover, although it must be said that a considerable number are not easily cultivated, yet there are a good many which present hardly any difficulty in this respect. Among the most easily cultivated, and at the same time one of the prettiest of slightly trailing habit is *Campanula garganica hirsuta*. I prefer it to the typical *C. garganica*, because of the more attractive appearance of the whole plant, with its hirsute foliage and pleasing flowers. It has another advantage in a somewhat slug-infested garden, inasmuch as these pests seem averse to the hairs on *C. g. hirsuta*, while they sometimes attack the typical *garganica*. As the ordinary *C. g. hirsuta* with its pale blue flowers is such a favourite with

for example, it may be best without this. What is greatly appreciated by the plant is a free root run, hence we do not see it in such perfect health where close tenacious clay abounds. As a free-flowering plant of shortly trailing, or even in some instances procumbent habit, I do not know its equal given the conditions named. The additional fact, too, that it is grown perfectly in gardens widely separated, as Ryde, Dublin, York, Middlesex, &c., making quite a feature by reason of its continuous flowering, should be an encouragement to many to naturalise it, so to speak, on bank or slope or rocky mound or any place where a perfectly free and beautiful flowering plant can be admired or appreciated. Above all it is easily propagated from cuttings, to which I will refer again, for in this way a colony of a hundred plants may soon be forthcoming.

E. JENKINS.

#### PROPAGATION OF ANDROSACE LANUGINOSA.

THOSE interested in this beautiful plant may like to know that this is an excellent time for increasing

also with the cutting soil, and though I still adopt it for the plants, I have to some extent diminished it when propagating, as I find the cuttings root quite freely treated as above. The cuttings should be firmly placed in position and thoroughly watered in and allow the leafage to dry again before covering up. Constant overhead watering will speedily kill the entire batch, as the woolly leaves do not readily dry up. When water is given the light should remain off for three hours or so, and at this time one watering per week will suffice. By this treatment a large number will root by spring, and many before, the state of the wood governing this to a large extent.

E. J.

#### NOTES ON LILIES.

##### LILUM HENRYI.

THIS Lily has been in cultivation since 1889, and so far as I know scarcely any variation has occurred in the shape or colour of the flowers. From the outset the plant, when grown under glass in a cool house, has differed markedly in habit from the wild form. The wild plant never is met with taller than six feet, and it has the stiff erect habit of stem of ordinary Lilies. Under cultivation it has more than doubled in height, and grows almost like a Bamboo, tall, graceful, with a stem bending over at the summit, and the number of flowers has increased extraordinarily. This year fasciation has occurred apparently for the first time. The photograph reproduced is of a plant growing in the garden of Mr. P. R. Kelly, of Paoli House, Athlone. He informs me that the number of flowers is over 200. The stalk is almost flat from the ground, becoming at the top quite flat, and there it is  $8\frac{1}{2}$  inches wide, with a thickness of only a quarter of an inch. The inflorescence measures in length 21 inches, and the total height of the Lily is 7 feet 5 inches. Mr. Kelly's bulb was sent to him some years ago from Kew at my instance, and it descends from my original stock. A similar case of fasciation has occurred this year in Mrs. Berkeley's garden.

Lilium Henryi, as a wild plant, has a very restricted distribution and a peculiar one, as it is met with in two localities differing markedly in soil, aspect, &c. In the Ichang gorge it was common on the rocky limestone ledges, where they were covered with short grass at altitudes above sea level of 1,000 feet to 2,000 feet, and in these wind-swept, sun-exposed situations it rarely exceeded three feet in height, and generally bore only one or two flowers. In the conglomerate mountains south of Ichang it grew taller, and bore often five or six flowers; still it never exceeded six feet in height.

The original stock from which the Lilies grown at Kew spring was a small number of bulbs sent by me from the limestone cliffs of the Ichang gorge in 1889. Some time afterwards I sent a small box of bulbs to Dr. Wallace of Colchester, and some of the stock of the Colchester firm is derived from this source. Afterwards Messrs. Wallace, in conjunction with a Japanese firm, imported into Japan some bulbs, which I believe were dug up in the same locality, and for years the growth of the plant on a commercial scale has been carried

on in Japan. During the present year Mr. E. H. Wilson has brought home a large number of bulbs, which were dug up in the conglomerate mountains near Ichang, and this stock is in cultivation at the Coombe Wood Nursery of Messrs. Veitch. At the show in Holland Park this summer Mr. Wallace and myself thought that there was a difference in the colour of the flowers of his Lilies and those of Messrs. Veitch; but this difference was due simply to forcing. Grown in the ordinary way in the open there is no difference at all between the Lilies grown at Coombe Wood, derived from the conglomerate mountains, and those at Kew, which descend from the limestone bulbs. It will be interesting to watch if in course of cultivation any differences arise.

The capabilities of Lilium Henryi for hybridisation were shown in the production of Lilium Kewense, which so strangely resembles the wild form of Lilium auratum. Indeed, it has been suggested that this last-named Lily may be a hybrid; but of the occurrence of it in an apparently wild state in Japan there is no doubt. It is somewhat remarkable that Lilium speciosum is not known in the wild state in Japan, according to Franchet and Savatier. It is, however, truly wild at Kinkiang in China. The Japanese have been importing plants for cultivation from China for centuries, and it would be a very interesting study for Japanese scholars to see if there are any records of the origins of many of their cultivated plants, such as these Lilies. I have pointed out elsewhere that Ichang, situated on the great river, was the probable source from which the Chinese derived some of their striking cultivated plants, as *Primula sinensis*, the *Chrysanthemum*, &c. It would be a strange thing, but one not inherently impossible, if *Lilium auratum* were really a hybrid of Chinese origin, which has become wild in certain parts of Japan.

AUGUSTINE HENRY.

#### THE FLOWER GARDEN.

##### WINTER SCHEMES FOR SUMMER COLOURING.

**W**E are indebted to our excellent contemporary *Country Life* for the following valuable suggestions by Lady Algernon Gordon-Lennox about summer borders, a subject that we know, from the many questions asked, is interesting to readers of THE GARDEN:

The few suggestions which I offer at this season, in all humility, on the important question of colour considered in relation to the flower garden are intended more especially for the practical guidance of those who possibly are not able, by means of pencil and brush, to illustrate with facility their own ideas, assuming, of course, that the garden is to be designed and the borders planted without the assistance of a landscape gardener. The additional time and thought required will be amply repaid by the ultimate satisfaction of feeling that the garden is of one's own creating, and that, even through failures, experience has been gained.

LILUM HENRYI FASCIATED.

(From a photograph kindly sent by Dr. Henry.)

it by cuttings. These are best if made entirely of the tips of the branches constituting the most recent growth of late summer, or indeed any of the terminal points do well for purposes of propagation. These may have an inch of stem attached, from which, when all the leaves are removed, the young bits are quite ready for insertion. Where a large stock is quickly needed, however, and the material at hand not over-abundant, the stems may also be cut up into short lengths and treated in the same way, except that some leafage must remain on the upper part of the cutting. In this way a large lot may be secured, not that all the stem pieces root quite so readily as the terminal pieces, for these are virtually crowns or rosettes of leaves. All that remains is to make up a square hand-light for their reception, filling up the square box nearly half its depth with very sandy loam, and covering the surface with about half an inch of pure sand. Formerly I employed old mortar or broken brick

STANDARD TREE OF ROSE BENNETT'S SEEDLING (THORESBYANA)  
IN THE GARDEN OF MR. S. HEILBUT, THE LODGE,  
HOLYPORT, NEAR MAIDENHEAD.

At Broughton the garden has grown up in this way. Four years ago the old castle looked down reproachfully, as if to chide neglect, upon a rough grass field, which has now given place to a semi-formal garden, the design of which we borrowed from a curious old picture at Dunrobin of a parterre at Heidelberg dating from the sixteenth century. Set within clipped hedges, and brilliant with herbaceous plants, it now forms a more worthy setting in these peaceful days to those old grey walls from whose shelter Nathaniel Fiennes, and the leaders of the Puritan party, sallied forth to do battle with the forces of the King. Borders bright with hardy flowers nestle against the battlemented walls; Delphiniums, Foxgloves, and Shirley Poppies fringed the moat, and seem never to weary of their own reflections in the still water, as if they were aware that each has a part to play in helping us to complete the colour scheme.

Is it, I wonder, the result of many happy hours spent in the sunny south, that to me colour is almost as indispensable as sunlight? Nowadays we have this great advantage, that colour in flowers—even as in materials and decoration—has been improved out of all knowledge. Instead of the old-fashioned sickly mauve and magenta Phloxes of our childhood we have been given such varieties as Coquelicot and Etna; the monotonous crimson and dingy pink of the Peony have yielded pride of place to the brilliant hues of the ones raised by Messrs. Kelway, Desser

Méchin and others; the wonderful shades to be seen amongst the Tea Roses—these are only a few instances of the revival of taste for *true* colours which has taken place in the flower world. There is, therefore, no excuse for want of harmony, but, in order to attain success, we must first learn to *study* colour effects; even as the painter determines what is to be the highest light in the picture, so must the most brilliant patch of colour in the border have its allotted place.

Some of my readers may never, perhaps, have realised how essential it is to adapt colour to surroundings; cool and delicate tints will appear infinitely more telling when planted in semi-shade, whereas a brilliant scarlet or yellow is intensified by the sun's rays. Nowhere is this effect of sunshine upon colour more forcibly illustrated than in the East: glowing hues which rejoiced the eye beneath a cloudless sky almost invariably appear garish and crude when associated with our grey English atmosphere, no longer wearing the same aspect as amidst their own surroundings. It is, therefore, manifestly impossible to dogmatise where gardening is concerned.

I can imagine many criticisms being passed on the general scheme of one of my borders, but for the present moment it will serve to illustrate this colour theory of mine. Running along a broad grass terrace, it faces south-west; behind it stands a crumbling, Ivy-covered wall, terminating with the beautiful old house which has weathered the storms of full six hundred years; not a tree casts its shadow anywhere, and the wall, sheltering the border, as it does, from the north

and east, is, in consequence, no protection from the sun's rays.

In such a position, brilliancy is obviously essential, for the beauty of the grey stone, mellowed by age, is enhanced a thousand-fold by the belt of glowing colour at its base, and nothing like the same effect would be attained were the predominating note a subdued one; on the other hand, where shadow can be secured, the more delicate the tones the more effective will they be.

In the making of a border, when planning a broad colour-effect, dimensions are important, owing to the fact that the width must determine the plants to be used; the broader the border the easier it is, to my mind, to plant it well, for colour is always more effective when massed. In narrow borders there is a greater risk of that fatal mistake of "spottiness," which so frequently destroys the effect of an otherwise good mixed border, because the clumps of each individual plant are not large enough.

In certain positions dimensions have to be governed by architectural features (a large illustration is given in our contemporary showing a case in point), for the distance between the projecting buttress of the building at one end and the termination of the wall at the other limited the total length to 119 feet. As one almost invariably finds in these early buildings, the wall, although starting from the house, does not run parallel with it. The border obviously could not project beyond the

buttress, so in order to ensure a true line for the grass terrace, which is continued under the windows of the house, it was necessary gradually to increase the width of the border from 7 feet 8 inches to 9 feet 4 inches.

I quote these measurements merely in order to show that, even where one has to adapt one's self to circumstances, it is possible by *careful* planting to secure a satisfactory effect of colour; but I would insist on the point that, where space is not limited by any such conditions as these, the broader the border the more effective will it appear.

(To be continued.)

#### RESERVE BORDERS FOR CUT FLOWERS.

THERE is an ever-increasing demand for cut flowers, but not always an inclination to rob the borders to obtain them, and sometimes when this is done there is a feeling that the display in the borders is not so good as it might be. It must be remembered that the flowers cannot be enjoyed both on the plant and in the vase. So it comes about that where the demand for cut flowers is great it is always advisable to have a fair amount of ground in some part of the garden where they can be grown for this purpose alone, and a judicious selection made so that the season is of long duration. This can now be easily effected and at very little expense, except, of course, where there is a demand for choice varieties in the different species, and we could just now (early in October) cut plenty of Delphiniums, Pyrethrums, Coreopsis, Penstemons, and Chrysanthemums in variety from plants that are the result of seed sown last March, and that are still in the border where they were pricked out waiting to be transferred to other quarters. Specially good just at present is Pentstemon barbatus coccineus, with spikes quite 5 feet long. It is a good plan to bastard trench the border for the reception of plants under notice, and to work in a fairly liberal dose of manure between the spits, as deep rooting and moisture-loving plants, and indeed all things, will be benefited by this treatment. A good surface mulching is also beneficial. It is impossible without monopolising too much space to give a list of the many things that are suitable; one important fact may, however, be emphasised, viz., that whatever the amount of space available a good variety of things should be planted, embracing a season that will extend right away from the earliest Daffodils until the latest Sunflowers and Aster. After one or two season's experience special favourites may be noted and added to as deemed necessary. For instance, Daffodils, Spanish and English Irises, Montbretias, white Pinks, single Pyrethrums, the Pentstemon noticed above, and perennial Aster are always in great request.

E. BURRELL.

### THE ROSE GARDEN.

#### WEEPING ROSES.

**A** WELL-DEVELOPED weeping standard Rose is a thing of beauty. Being isolated as it should be upon a lawn, or grouped by the main walk, the huge heads of growth after the trees have been planted some four or five years are very charming, surpassing, in the opinion of many, all other flowering weeping trees, and producing, as Dean Hole says, "a fair dome of Roses." A Rose garden is certainly not complete without a few weeping Roses; not, of course, grouped in formal lines, but placed where the trees will stand out well. As weeping Roses attain to such large dimensions, obviously they need special care when planting. They are usually budded upon the finest Briar stocks procurable, and should have an abundance of fibrous roots if they are to be a success. The thick-

ness of stem is no criterion as to the vigour of the tree. A young, thrifty Briar will quickly overtake the stout hide-bound specimens often seen, so that when selecting weeping Roses this important point should be remembered.

For each tree I would recommend that the ground be trenched 2 feet to 3 feet deep, and from 2 feet to 3 feet wide each way. If the soil is at all poor, replace with better from the kitchen garden or add some good turf loam. Manure, well decayed, should be incorporated at the rate of about one-fourth the bulk of soil. After allowing the latter to settle a few days the trees may be planted. Iron stakes, the same height out of the ground as the stem of the tree, should be first placed in position, then a hole opened wide enough to allow the roots to be spread out without bending them. The roots, having been previously wetted and jagged ends smoothed over, should be placed about 9 inches below the surface. Some well-prepared compost gently worked in among the finer roots will give the trees a good start. More soil is placed in the hole and firmly trodden, the final soil being allowed to remain somewhat loose, and the surface covered with short manure. On no account allow grass to be laid nearer to the stem than 12 inches, the ground being covered with Pansies or some surface-rooting plant if the bare soil be objected to. The method of pruning weeping Roses varies according to age. For instance, the first spring after planting the growths should be cut back rather severely to promote long, pendulous young shoots. The following year these shoots should not be pruned at all, but a wire frame placed beneath them and the growths regulated by tying to this frame. These growths will send out numerous spurs or laterals, which are shortened back each spring. As the heads become dense, cut out a few of the oldest growths, which will induce new ones to break, and thus give to the tree a youthful appearance. When established, aids to good cultivation consist in liberal doses of liquid manure during winter and also in May and June, and again after flowering, and, if at any time it is thought that the liquid does not reach the roots readily, holes made with a

crowbar round about the stem and afterwards filled up will create a passage and also admit air to the roots. Formerly, the

#### SELECTION OF VARIETIES

suitable for this purpose was limited to the Ayrshires and sempervirens Roses, excepting the Boursault and Hybrid Chinas, which were anything but suitable, but now the introduction of that charming tribe Rosa wichuriana and the varied variety of R. multiflora has given the planter a more extensive selection. The accompanying illustration of R. thoresbyana, or Bennett's Seedling, faithfully depicts this lovely Rose to perfection, and when its growths touch the ground the effect is very fine. Other good kinds of R. arvensis are Ruga, Dundee Rambler, Queen of the Belgians, splendens, and Virginian Rambler, and from the group of R. sempervirens three of the loveliest are Félicité Perpetue, Flora, and Myrianthes Renoncule. But I think all of these must give place in gracefulness of growth to the hybrids of R. wichuriana. The fine pot-grown specimens of some of the newer varieties exhibited at Holland House in June last were object-lessons of the possibilities of this group, and these will be well supplemented by that most charming addition Dorothy Perkins.

There is one kind I should like specially to direct attention to, and that is Evergreen Gem. Rather a shy bloomer, it nevertheless makes up for this by its graceful growth. The slender shoots and neat foliage must be seen to be fully appreciated. Then, too, the charming group of R. multiflora, such as Crimson Rambler, Aglaia, Euphrosyne, Thalia, Electra, and Queen Alexandra, add a rich variety, every one of them capable of making a perfect floral picture.

I am persuaded the future demand for standards will be for Roses of this character and Roses that make fine large heads. The stumpy-headed kinds of the Baroness Rothschild type must give place to the glorious-headed trees such as the kinds already mentioned, and also of lesser vigour but more perpetual type of Gruss an Teplitz, Mme. Alfred Carrière, Aimée Vibert, Corallina, and many others.

#### PHILOMEL.

NO. 1.—A SUITABLE SITE FOR A ROCK GARDEN, SHOWING PREPARATORY WORK.

## THE ROCK GARDEN.

### ROCK GARDEN - MAKING.

#### 11.—SUITABLE AND UNSUITABLE SITES.

In introducing the subject of rock gardening I have already pointed out that no rock garden can be a success unless it represents a piece of wild, rugged Nature. Hence it follows that the site for a rock garden must under all circumstances be an irregular one. And if it is not naturally irregular it must be made so by excavation or filling. An unsuitable site can never show rockwork of any kind to advantage. Even if the rock itself should have been skilfully executed it will look out of place if the site and its immediate surroundings do not justify its presence. Such would be the case, for instance, near a large mansion standing on a flat expanse of almost level ground. In such a position the repose or dignity produced by an extensive lawn would be entirely destroyed by the unjustified introduction of rocks on almost level ground. Even if, where the rocks are desired, irregularity is produced by sinking a large pit, a rock garden on such a site would still look unnatural. If the surrounding ground is flat the artificial depression would be meaningless, and it will appear as if it had no business to be there and ought to have been filled up. It is seldom possible to produce a good rock garden near a house, as, naturally enough, in almost every garden the immediate surroundings of the house would be treated with more or less regularity.

The case is different, however, if the house stands on hilly ground, or, if in order to produce the level space required for the house, it was found necessary to cut deeply into the hill, leaving steep banks almost close to one side of the building. By still deeper excavation and by making irregular recesses such a site can often be made most suitable for a rock garden. In all probability it would be possible to face the rough, irregular banks with stones in such a way as to convey the idea that the house was built in a large recess sheltered on one side by natural rocks. Nor would it be necessary to face the whole bank with stones, for often a somewhat scattered appearance of rocks protruding from the surface only here and there looks more natural and picturesque than more massive structures, to say nothing of the greater facility in construction and the reduction in the cost.

The most unsuitable sites for rock gardening are long, straight, and narrow borders. For wall gardening they may be ideal sites, but to produce in them the natural appearance demanded by a rock garden will in most cases be found impossible. The site for a rock garden should not be near large trees. Not only would it be impossible to grow the choicer kinds of alpine plants under the drip of trees, but the latter would also send their hungry roots into the crevices prepared for the rock plants. They would not only exhaust the ground but would in time dislocate the stones by the swelling of their roots. Where it is impossible to keep the rock garden far enough away from such trees as to be out of harm's way, it would be best to cut a

deep, narrow trench, say, 12 feet or so in depth, filling this with a concrete through which even the roots of large Elm trees could not penetrate. This, however, adds considerably to the cost. In laying out a garden it often happens that after the more or less regular parts near the house have been completed satisfactorily there remains some remote corner which is quite irregular, and the owner is at a loss to know what to do with it. The probability is that such a spot could be made into an ideal rock garden. Such a site is shown in illustration No. 1, which represents the ground set apart for a large rock garden constructed in some extensive private grounds at Paignton. That the site was a suitable one may be gathered from the second illustration (No. 2), which was prepared from a photograph I took twelve months later. In the centre of the first picture will be seen four large Palms (*Chamaerops excelsa*). In the second picture the same four Palms appear more to the right, because the photograph was taken from a slightly different point in order to obtain a better view of the now completed rocks in the background. I shall again refer to these illustrations during the next paragraph on

#### PREPARATORY WORK.

The work required for preparing the site chosen for a rock garden is of a very varied character, according to circumstances. If the ground is comparatively flat it will be necessary to excavate in some places and fill up the extra soil so obtained in other places in order to ensure that indispensable irregularity of outline. But even if the ground is already irregular it will, as a rule, be advisable to make that irregularity still greater. Thus by deepening a recess, and by still further projecting a prominent part, we emphasise the irregular effect.

Sometimes constructors of rock gardens have the soil roughly shaped to represent the desired effect as it would appear when the stonework is complete. This principle I consider altogether wrong and most misleading; besides this it hampers the work, and is more expensive from the fact that soil has to be shifted several times over. During my own practice I have always found it most desirable to have a great deal too much room rather than not enough, and I hold that rock building should commence with the stones and not with the soil. If there is plenty of space one is at greater liberty, too; as regards outline, the best method of rock building I have always found to be filling in the soil behind the stones as the work proceeds, and not placing the stones on the top of a heap of soil as is so often done. Where a recess is wanted it should be excavated very much deeper than really required, allowing not only for the thickness of the stones to be placed against its sides, but also for a fair quantity of good soil to be filled in between the stones and the remaining bank.

Most important is preparatory work in connexion with water, such as the construction of a new pond or streamlet. Especially is this the case when there is not a constant stream of water, but when the supply is limited and it is necessary for the new pond or streamlet to consist of cement work which is to be masked with soil and stones afterwards. If the space allotted to such a pond has to be

NO. 2.—THE SAME SITE AS ILLUSTRATION NO. 1 TWELVE MONTHS LATER.

entirely excavated out of solid ground, the sides of the pond would be cut to the proper shape, and the cement concrete would be placed against these sides in a somewhat sloping position. But if (as was necessary in the case represented by illustration No. 1) the conditions are such that a portion of the pond would be on a higher level than the ground was before, then stout walls must be built, which are afterwards supported by large quantities of soil, forming outside banks in such a manner as to be dipping towards—not away from—the water. I shall go more fully into this matter when speaking of water gardens in connexion with rocks, but one most important item in connexion with preparatory work for ponds must be pointed out here. In order to prevent the cement concrete or walling of a pond from being visible after the work is complete, it is necessary to build a kind of shoulder about 6 inches or 8 inches below the actual water-level. This shoulder is to support either stones or turf which might thus dip right into the water and prevent a stiff appearance.

In the background of illustration No. 1 such a step or shoulder is clearly visible around the space for a pond close by the large trees. Illustration No. 2 shows in the foreground a small portion of the same pond twelve months later. The stones and turf are resting on this shoulder below the water-level, and not a trace of the shoulder or masonry of any kind can be discerned.

With regard to other preparatory work I may briefly mention that, as a matter of course, good drainage must be provided, and that in excavating portions of the ground good soil and bad soil should never be mixed before the actual rock building commences, but should be put aside in separate heaps easy of access when wanted. It would also be well to deposit the stones or other materials required not too close to the place where they are to be used, and to spread them out so that any individual stone might be easily selected without turning

over the whole heap. If the stones are deposited "best side upwards" it will greatly facilitate the work and save a lot of turning over. If placed too close to the field of operations the stones are too apt to be in the way, and sometimes have to be moved several times.

#### APPLIANCES FOR MOVING AND CARRYING STONES.

When the rock garden is on a large scale, necessitating the removal of stones weighing sometimes several tons, a small trolley running on portable rails, like a miniature railway, will be found of enormous advantage in saving labour.

Illustration No. 1 shows a stone about a ton in weight resting on such a trolley, which can be easily pulled along the rails. The rails are shifted in any direction within a few minutes, and are supported by planks. This method, however, would of course apply only to work on a very large scale. A most handy appliance is a little two-wheeled trolley with a long pole, which might be made to act as a lever in loading the stone. But stones up to two tons in weight can easily be shifted without any other appliances than planks, rollers, and iron bars or wooden hand-spikes as levers. If such a stone rests on a broad plank or, better still, on a couple of short planks clamped together side by side and running on rollers supported by planks on the ground, it will be found an easy matter to move it by forcing it on with levers. For hoisting heavy stones a large tripod and double blocks are usually employed. If it is possible to land the stones so that, in order to be put into position, they have to be let down instead of being hoisted, an iron winch will be found most useful in letting them down gradually. This will be treated more in detail when dealing with the actual fixing of stones in a subsequent chapter.

*Elmside, Exeter.*

F. W. MEYER.

(To be continued.)

## GARDENING OF THE WEEK.

## INDOOR GARDEN.

*RICHARDIA ETHIOPICA.*

**G**ROWERS differ somewhat in their treatment of this plant. We have for several years planted part of our stock out in trenches, and the other we have kept entirely in pots, allowing them to go to rest and remain dormant until early in August. By both methods the plants come into flower during September, and produce spathes all through the winter months. They should be placed in a situation fully exposed to light and sunshine in order to get the growths well matured. Plants for an early supply of flowers may be placed in a warm temperature, affording plenty of light and moisture. An excess of water at the roots should be guarded against. When the pots are full of roots plenty of manure and soot water should be given them. *R. elliottiana* should be allowed to go to rest by gradually withholding water. The pots containing the tubers may be placed under the greenhouse stage on their sides until starting time.

## WINTER-FLOWERING PELARGONIUMS.

These are now coming into flower, and should be given a warm and rather dry temperature, allowing the plants all available light. Watering ought to be done in the morning. Spot and decay at the base of the stem are often caused by faulty watering. Stimulants should be carefully administered during winter. Freely ventilate on favourable occasions, avoiding cold draughts, which are most injurious.

## FUCHSIAS

that have passed out of flower should have less water, so that the plants will gradually go to rest. Fuchsias when dried off too suddenly often have their roots killed. The soil should remain slightly moist during winter, for the plants will then be in a better condition than if it is quite dry. Store the plants in any dry situation where frost can be excluded.

## IXORAS

are amongst the most handsome and useful of stove-flowering plants, and it is difficult to understand why they are so little grown. Short-jointed and moderately firm cuttings should be inserted singly in small pots and plunged in a propagating frame having a brisk bottom heat. They thrive in a compost of fibrous peat, leaf-soil, and sand. Cuttings rooted now, if kept potted on, given a high temperature, and supplied with plenty of moisture will make nice flowering plants in 4½-inch pots by next June. Specimen plants which have ceased to flower and have made free growth should receive less water at the roots. They should be sponged over frequently, and the stems well searched for scale, to which they are very subject.

## MALMAISON CARNATIONS.

Very little water will be required at this season, moisten the leaves, keep the house dry, and give air at all times. Keep a sharp look-out for insect pests and vapourise with XL All.

JOHN FLEMING.

*Wexham Park Gardens, Slough.*

## THE FRUIT GARDEN.

## PLANTING BUSH FRUIT TREES.

Owing to the bad weather the planting season of hardy fruit trees will be later than usual this year. Assuming that preparations as previously advised have been made for the work, there should be no delay in commencing when the foliage falls by taking those trees in hand that become bare first. In planting, the depth to place the bush in the soil is of considerable moment, and usually they may safely be planted the same depth as they were before being lifted from the nursery. The roots after having their jagged ends removed by a clean upward cut should be spread in a slightly declining position in shallow holes. Avoid planting when the soil is wet or cold, and place fine soil im-

mediately around the roots, making the whole quite firm by treading, and complete the operation by mulching with short litter. Should the roots be dry when the bushes are received soak them in water before planting.

## RED AND WHITE CURRANTS.

These prefer an open sheltered situation and a well drained loamy soil, not too stiff. Young properly furnished bushes possessed of short stems should be selected, and when plantations are formed the rows should be 6 feet apart each way. Trained plants with branches about 10 inches apart and cordons are suitable for planting against walls or upon trellises, and in this way can be conveniently protected from birds. Standards upon 3 feet stems planted by the sides of walks are both ornamental and prolific. The following are excellent red varieties: Cherry, Fay's Prolific, Red Dutch, Raby Castle, Knight's Early, Warner's Grape, and La Constance; white varieties, White Cut-leaved, White Grape, and White Versailles. Gooseberries require similar treatment, but in planting, for the sake of convenience in protecting them from birds, keep the dessert varieties from those grown for gathering the fruit in a green state. Red Warrington will prolong the season if planted against a north wall.

## BLACK CURRANTS.

Unlike most fruits these do not resent a somewhat shaded position, and they delight in a tolerably damp heavy soil. They are, however, impatient of exposure to strong winds, and if subjected to them, especially if grown upon single stems, they are very liable to be much disfigured and broken.

## RASPBERRIES.

Amongst bush fruits these take a high place for preserving purposes, Superlative, Red Antwerp, and Carter's Prolific are reliable red sorts. The best yellows are Yellow Superlative and Yellow Antwerp. Of autumn bearers, Belle de Fontenay, October Red, and Yellow Four Seasons are useful. For private garden culture the Raspberry is best grown in rows from 5 feet to 6 feet apart, with the plants 2 feet asunder, and supported by permanent trellises.

## FILBERTS AND COB NUTS.

The fact of these having been very prolific this year, while other hardy fruits have been generally scarce, may give an impetus to their culture, particularly as they succeed in many cases upon land, provided it is drained, too poor for other fruits to flourish upon. Twelve feet is a suitable distance for the bushes to be planted apart, and of varieties Kentish, Webb's Prize, and Cosford Club are good Cobs, and Prolific, Red Exhibition, and Purple-leaved desirable Filberts.

T. COOMBER.

*The Hendre Gardens, Monmouth.*

## ORCHIDS.

## HEATING AND AIRING.

In the Phalenopsis, warm Cypripedium, and stove Orchid houses maintain a temperature of 70° by night and 75° by day by fire-heat, admitting a little air by the lower ventilators when the weather is not cold or windy; Cattleya houses, 65° by night and 70° by day; Mexican houses, 60° by night and 70° by day, admitting air more freely by the lower ventilators and a little by the top ones on all favourable occasions; cool Cypripedium houses, 60° by night and 65° to 70° by day, always allowing a free circulation of air by the bottom ventilators, using the top ones when not cold or windy; cool intermediate houses, 55° to 60° by night and 65° by day, admitting air freely by the bottom ventilators and top ones when the outside conditions are favourable; cool houses, 50° by night and 55° to 60° by day with free top and bottom ventilation, never entirely closing the house unless the outside temperature is as low as freezing point.

## WATERING THE PLANTS.

Great care is needed at this season, the genus, species, and variety must be considered, if growing or resting, and watered accordingly. Phalaenopsis, Cypripediums, Masdevallias, and many bulbous

Orchids must never be allowed to become too dry at the root or they suffer. Cattleyas, Laelias, and many of the Oncidioms may be allowed to become much drier before water is applied. This also more forcibly applies to Dendrobiums, the deciduous species in particular; *Dendrobium Dearei*, *D. revolutum*, *D. atroviolaceum*, &c., require more warmth when resting, and should not be allowed to shrivel.

## DAMPING THE HOUSES.

The weather must now be taken into consideration. The cool and cool intermediate houses will need but little damping during damp mild weather, when a little fire-heat is required. The Cattleya and Mexican houses, too, had better be kept on the dry side rather than have too much moisture in the atmosphere or decay of the improperly ripened pseudo-bulbs may take place. Excess must also be guarded against even in the warm houses or too much moisture settles on the foliage at night, and finds its way down into the axils of the leaves, which sometimes has a very injurious effect upon some species of Orchids, causing the base of the lower leaves to decay. Some of the Selenipediums are quickly affected this way, likewise the bellatulum section of Cypripediums, and such others as *C. rothschildianum*, *C. Stonei*, *C. levigatum*, and many of the hybrids derived from plants liable to be affected in this manner.

## SHADING.

The aspect of the different houses must now be considered, and shading dispensed with wherever possible. The Phalenopsis, Cypripediums, Masdevallias, Odontoglossums, and such like tender Orchids will still need shading during the brightest part of the day.

## REPOTTING.

Among the numerous Orchids there may be a few plants in the right stage for repotting during the latter days of autumn and winter, but the majority have now been done, and as few as possible should be disturbed at the root after this date.

## SYRINGING.

Little overhead syringing is needed at this season, yet such plants as the Odontoglossums, Miltonia Roezl, some of the Cypripediums, and plants that are subject to the attacks of thrips are benefited if sprayed lightly overhead once on bright days.

F. W. THURGOOD.  
*Rosslyn Gardens, Stamford Hill, N.*

## THE KITCHEN GARDEN.

## GLOBE ARTICHOKES.

THESE have done well this season, especially of late, and unless we get severe frost good heads may be cut well into November, and they will well repay protecting whenever the glass shows signs of falling to freezing point. The heads should be tied together and three stakes placed round when the slightest covering will make them safe against a few degrees of frost.

The better kinds are much more tender than the common ones, many of which are not worth growing, and to ensure keeping up a good stock of these, strong suckers should be potted up every autumn and wintered in a place of safety, either in cold frames or plunged at the foot of a south wall in leaves or ashes, where they can be easily protected if necessary and planted out early in April. These will give excellent returns in late autumn. The best and most prolific variety to grow is the large green, which has scarcely any prickles. Those raised from seed can never be depended upon to come true. The best purple is very good in quality, but scarcely large enough for general purposes.

## CARDOONS.

Give the final earthing to these, banking up plenty of soil to ensure perfect blanching, without which they are of little use.

## BEETROOT.

is a splendid crop this season, and all should now be lifted. Do not cut the foliage but twist it off with the hands, and then store away the roots in the root-room in their different sizes, either in

sand or finely-sifted cinder ashes, and any that may be required for very late spring use will be best if clamped under a north wall, making sure that plenty of protection is given.

#### CELERIAC.

Continue to take advantage of fine weather to earth up the latest plantings. Every care should be taken to break up the soil as finely as possible and place it firmly round the stalks, as when slovenly done it never keeps well.

#### CELERIAC.

If not already done this should be lifted and stored in sand, where it is proof against frost.

#### LEeks.

Complete the earthing up of the late plantings as speedily as possible, but before doing so make quite certain that the roots are not dry, for at all seasons these require plenty of moisture.

#### CUCUMBERS.

Much attention must be given to those plants which are expected to yield supplies all through the winter. In the first place there must be plenty of heat at command, both bottom and top, or it will be useless to expect them to do satisfactorily. The plants should now be strong and well established, and over-cropping must in no case be indulged in. Immediately the fruits are of a fair size they should be cut, the ends placed in about half an inch of water and kept in the same temperature as that in which they have been growing, when they will keep in good condition for ten days. The growths should be moderately thinned and stopped one joint beyond where the young fruits show. Syringe with tepid water about 8 a.m. on bright mornings, and again about two in the afternoon. The evaporating pans should be filled with manure water and a small surface-dressing frequently given. Use a light, porous compost, which should be well warmed before applying it. Fumigate frequently when the foliage is quite dry to ward off attacks of thrip and green and black fly, and dust the growths when any sign of mildew appears. Sufficient moisture must be given in a warm condition to the roots or the fruits will be bitter, especially at this season, when they grow slowly, and red spider also will be sure to attack the plants.

#### FRENCH BEANS.

Make another sowing of these in pots and nurse along near the glass in heat.

E. BECKETT.

## ORCHIDS.

### ORCHIDS AND LEAF-SOIL.

**R**ECENT contributions to THE GARDEN on the use of Belgian leaf-soil (*terre brûlée*) for Orchids go to show that most authorities wish to preserve a non-committal attitude on the subject, possibly a wise course, but one which is not likely to encourage an enterprising attitude among growers generally, who do not care to risk accidents with valuable plants and prefer to go on in the old and comparatively safe way. The illustration, from a photograph, published with this may help in a small way to dispel doubts as to the suitability of the material for Cattleyas. It shows a plant of *C. Mendelii* which has been in its present

(6-inch) pot for over three years, and is only one of many now growing well in leaf-soil here. A careful examination of the illustration will show that the growths made since the plant was potted are a great improvement on the older ones, and this improvement has been progressive each year, not only in the pseudo-bulbs and leaves, but in the size and substance of the flowers. At first it was thought that there was a slight falling off in the substance, but this was only noticed in the first year, and may have been more fancied than real, or it may have occurred through some slight error of treatment; in any case it has not only disappeared but the difference now is quite the other way. One thing the illustration cannot show, and that is the great

water is necessary it is only given close round the sides of the pot and not sufficient to run over the surface. If leaf-soil comes into general use it will help to solve the question of pruning, for Cattleyas spread outwardly so fast that to keep the new roots within the bounds of the pots some of the old back bulbs and rhizome must be cut away, severing the rhizome some months before disturbing the roots. If potted on intact, increased size of pot would be too great, as it is useless to let the new breaks hang outside the rims, for the roots would not then find their way back into the soil.

We have severed the rhizomes of many plants, and the results of potting these are very promising. It will be seen that the plants are not raised on a mound, but rest at about the level of the pot rim, and this method is followed in every case without any bad effects on the young leads when they appear.

In addition to Cattleyas, we have used this soil with beneficial results on many Dendrobiums, including *D. Phalaenopsis schaeferianum* and *D. formosum giganteum*; Oncidiums, including *O. marshallianum* and *O. varicosum* var. *Rogersi*, also on Vandals and some others; but do not find it a suitable rooting medium for Cypripediums. I may say that I have used only the Belgian leaf-soil, which differs from the home product, as it apparently contains a large quantity of very fine silver sand.

## NURSERY GARDENS.

### CACTUS DAHLIAS AT SILVERHILL PARK, ST. LEONARDS.

**D**URING late years the improvement of the Cactus Dahlia must be of interest to all lovers of floriculture, and for the rapid strides in its

recent development we are in no small measure indebted to the strenuous and successful efforts of Messrs. Stredwick and Son, of Silverhill Park, St. Leonards. A visit

paid to their gardens last month, when the flowers were in their full beauty, proved of the keenest interest, and grand new things were met with at every turn. Messrs. Stredwick devote themselves chiefly to the Cactus Dahlia, and this often gives them a point or two when competing with other growers who have several irons in the fire. To do one thing, and to do it thoroughly well, is no doubt best. It was only about six years ago that Mr. James Stredwick, in conjunction with his son, commenced the cultivation of Dahlias for profit; they had for six years previously exhibited as amateurs, and the success of the pastime no doubt stimulated them to take the matter up in real earnest.

We first went through a plot filled with what I thought at first sight were a grand lot of new varieties. "These are all failures: we shall throw them away," was Mr. Stredwick's remarks, and on closer inspection one could detect here and there on some of the plants a flower with a faulty centre, another perhaps a little too heavy or in some other way not quite up to Mr. Stredwick's rigid standard. On my venturing to make a remark on the subject, he replied that with such a wealth of new material as he had to select from

CATTLEYA MENDELII IN BELGIAN LEAF-SOIL.

he would not introduce to the public any flower which was not as near perfection in size, shape, colour, height, and habit as is possible. Before sending out new varieties, constancy is also ensured by growing the plants on heavy, light, and medium soils. With regard to the fancy varieties, any flower showing the least tendency to revert to the self colour is rejected. All these precautions indicate a policy to be recommended to those raisers who each year put on the market a flower heralded with a glowing eulogy, which, on being cultivated, frequently turns out to be perfection only as far as its catalogue description.

I next inspected the new seedlings shown and certificated this year, and they were an object-lesson of the careful method of selection pursued by Messrs. Stredwick. H. J. Jones is an absolutely novel flower of most delicate colouring, primrose centre, shading to pink at the tips of the petals; Eva, as nearly pure white as possible, and undoubtedly far and away the best white up to date; W. F. Balding, shaded yellow of excellent shape; Etna, lilac and buff; and Vesuvius, a most showy and brilliant flower, yellow ground, striped and splashed with crimson-scarlet, another example of the race of fancy Cactus Dahlias of which Alpha, introduced by Messrs. Stredwick last season, was the pioneer. Other good new ones to be noted

view one may safely prophecy that the firm will maintain and enhance its well-known success as raisers and distributors of one of the most beautiful and popular of garden flowers. F. H. C.

## THE FRUIT GARDEN.

### AUTUMN STRAWBERRIES

**O**f late years more attention has been paid to the culture of the late varieties of Strawberries, and the perpetual varieties have found more favour. Such kinds as the St. Joseph and St. Antoine de Padoue and the alpines have much extended the Strawberry season, although the season for the late varieties cannot in some soils and situations have altogether been favourable, and this points out the necessity of varying the culture. We have the St. Joseph and others on different aspects, and in hot dry seasons such as we have had for several years past, our best fruits were obtained from north or north-east borders, but this year a much better position will be necessary to get late fruits to ripen well. The autumn Strawberries may be

divided into three sections, the true alpines, the hybrid or perpetual varieties, and the summer fruiters, grown for autumn supplies, that is a second crop grown from forced plants or young plants of certain varieties denuded of their first blossoms and made to produce a second crop. Now the last named can scarcely be termed autumn varieties, although they can be made a profitable crop, and unless I briefly refer to them I fear some readers may take me to task for omitting them.

#### ALPINES.

Doubtless the alpines should come first; these need more care to get the best results. At Gunnersbury House, Mr. Hudson grows them to perfection, and in the autumn gathers fruit daily. The hybrid

varieties are equally well grown; of course these are grown from runners, and the culture is more simple. Raising Strawberries from seed is most interesting, and to be a success should be carried out systematically. Seed is readily obtained of the best varieties from our leading growers, and it is an easy matter to save seed of any good variety and sow early in the year. Some cultivators sow it as soon as gathered, but during the winter months the plants make good progress, and I prefer sowing early in the year. Sow in pans or boxes in light rich soil in frames or in a warm house, and when large enough prick out the seedlings into cold frames on a rich root run, or, what is better, on a bed with a little warmth. In a few weeks transplant to proposed borders in the open, lifting carefully and preserving the roots. The plant is remarkably hardy, and seedlings may be raised in the open ground if sown in the spring in rich soil in drills 6 inches apart. Transplant in rows 15 inches to 18 inches apart and half that distance in the row. For alpine Strawberries it is well to have a well-prepared quarter; they do well on narrow borders under a south or west wall.

The alpine varieties are not numerous. There are about half a dozen really good kinds, and certainly one of the best is Gunnersbury Alpine, a

long, large red bright fruit of splendid flavour and very prolific. Many persons object to the alpines on account of their small size; this is one of the best as regards size. Belle de Meaux is a large red berry of good flavour. The Sutton Alpine is a good fruit, larger than the older kinds, and when raised from seed sown under glass early in the year gives grand fruit the next autumn. The White Alpine is much liked by many; it is a small round fruit, and produced in abundance. There are also the Hautbois alpines, which are noted for their rich aromatic flavour: they are not so much grown as they deserve, for they are very prolific. The two best are the Royal Hautbois and the older form, Triomphe de Orléans. When the alpines are grown from runners it is well to remove the first blossoms to get autumn fruits.

The St. Joseph was one of the first of the useful perpetual Strawberries, and was raised by crossing the true alpine with a garden variety. Its fruits may be had from June to November. The best way to secure a full autumn crop is to remove the first blossom. This forces the plants to make a free runner growth, and on the latter fruits are obtained. If runners are planted in spring in good land, 18 inches between the rows and 12 inches between the plants, and the first blossom removed, the beds will be in good condition by September. I do not advise leaving old plants, except to get runners, or after the runners are taken to get earlier fruits than the younger plants would provide. Much finer crops are secured by autumn planting and one season's crop. I have found raised borders of great advantage for a latest supply. If the soil is wet or clayey the crop is poor. Flowers are often produced so late that they cannot set, and it is a good plan to lift these plants into frames or pots and place them under glass, when good fruit may be had. I have also seen runners potted up in June in 4½-inch pots grown on and placed under glass in October for a later autumn supply. There are other good kinds in this section. The new St. Antoine de Padoue is a very good fruit, a cross between Royal Sovereign and St. Joseph. St. Antoine is a larger fruit than the latter, and equally prolific. Louis Gautier is also a perpetual. This is a white fruit (large for this section) and of good flavour. Another variety worth naming in this section is La Constante d'Automne, a very free bearer and very late.

I have referred to plants forced in pots and then planted out for autumn supplies, and for this purpose Vicomtesse Hélieart de Thury is very good, and gives a fair return. Though not strictly an autumn fruiter grown thus, it gives two good crops in one year. Another plan to get an autumn supply is to remove the blossoms in July, and late young plants are best for the purpose, or say late runners put out now, planted rather close, and treated as advised. With the advent of the new perennials there is now less need of the ordinary varieties for autumn fruiting. G. WYTHES.

#### PEACHES IN 1902.

In spite of the want of sunshine we have never had Peaches on walls better for size and colour than those produced this season. Anyone would have thought the flavour would have been inferior, but this is not the case. I have not seen a single fruit split, which is not often the case with some varieties. There can be no doubt that the abundant rainfall in this part of the country suited the trees, ours being a very light soil, and I think to this fact we owe our good fortune, as doubtless in a clay, cold soil the results would have been different. There can be no question that Peach trees require more water than they often receive, as frequently the roots in light soils are dry, and in many cases the walls are responsible for this. The same remarks apply to the Nectarines.

In our case some of the best Peaches this year—and they were really fine—were on those trees that we feared had set a poor crop, but there was a fair crop when the fruits had matured, and this shows the necessity of early and thorough thinning. Anyone would have thought that in such

LATE STRAWBERRY ST. JOSEPH.

were: Raymond Parkes, deep crimson, very free-flowering; Mary Farnsworth, yellow at base, white tips, very pretty; King Edward VII., orange and terra-cotta, very large, incurving; H. F. Robertson, deep pure yellow, described as always fit for exhibition; and Comet (another of the attractive fancy Cactus section), pink ground, speckled and striped with scarlet, of good Cactus form.

Mr. Harry Stredwick, who has throughout been associated with his father in the Dahlia business, and who obviously possesses horticultural enthusiasm, afterwards accompanied us round the large batches of this year's seedlings. In this connexion it may be mentioned that about 6,000 of these are raised annually here. Just before leaving I was shown a large bed entirely composed of all the known white varieties of the Cactus Dahlia, grown in this way for the sake of comparison. One could not help noting the immense improvement of the new St. Leonards varieties on the old Miss Webster, Keynes' White, and the like. It would be well to remark that Mr. James Stredwick's ideal Cactus Dahlia is a dwarf plant, a flower of exhibition size, but escaping grossness or coarseness, claw-like, but not intensely incurved petals, and a full, deep centre, the bloom carried on a stiff stalk well away from the foliage. With these worthy objects in

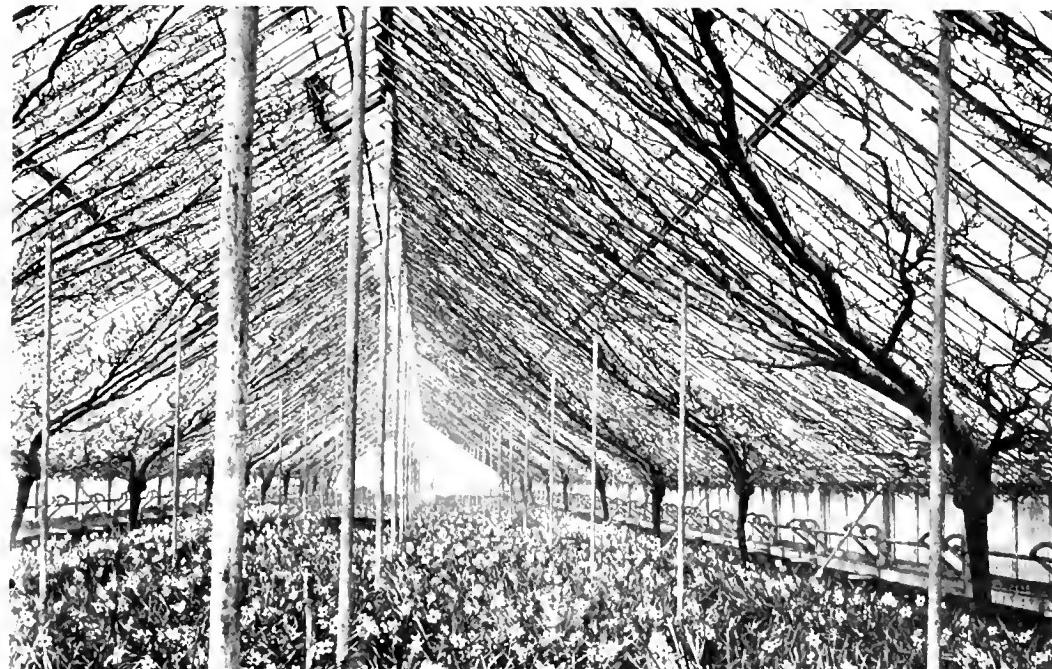

a season as the past the late Peaches would have been later than they really are, but at the time of writing (September 30) I find our latest varieties are not much later than usual; for instance, we have just cleared trees of Walburton Admirable and Princess of Wales. Of course, such varieties as Golden Eagle and Lady Palmerston, golden-fleshed Peaches and second-rate in quality, are far from ripe yet; but, on the other hand, we have had these varieties in past seasons late in October before being ripe, and this after a hot summer. Another interesting point is the absence of mildew, in spite of the cold weather. So far, we have none on these trees, but we usually have had it badly on some large trees of Royal George in the past.

I am aware with such luxuriant growth on both the Peach and Nectarine this season there may be some difficulty in ripening up the wood this autumn. It would be well, therefore, to cut out old fruiting wood or any not required for extension as soon as possible to allow the sun to reach the trees fairly. In many cases the wood in such seasons as this will be much crowded.

No note would be complete without a brief reference to some of the newer varieties, and among the Peaches we have a splendid fruit in late Devonian. This season this fruit is very fine and of good flavour; it is a mid-September variety. Thomas Rivers will, I think, be a splendid addition, but in our own case the trees were too young to properly test their fruiting qualities. An older variety but not often seen, the Marquis of Downshire, is a really fine late September Peach, and well worth space in all gardens. The Early Rivers' Nectarine was very fine; it gave us our largest open wall fruits of the season. Though we have fine trees of older kinds, there can be no question as to its usefulness.

Among late Nectarines this season Spenser has been specially good, and is just over from trees on a south-west wall: the flavour is very fine, and the fruits large. The Peaches give so many really good fruits that there is no lack of varieties. Our most profitable late varieties are doubtless Sea Eagle, the Nectarine Peach, and Late Devonian. Grosse Mignonne is a fine mid-season fruit, and to this may be added Stirling Castle, Bellegarde, and Royal George, and Waterloo, Amsden June, and Hale's Early for earliest supplies.

G. W.

IN A MARKET NURSERY : HOUSE OF PEACH TREES AND DAFFODILS.

collections in the country. These he forces in thousands every spring in his Peach houses. Planted on the border in the autumn at the fall of the leaf they remain dormant during early and midwinter, but are excited into growth early in the new year by the heat applied in starting the Peach trees, and before the trees are in leaf the crop of Narcissus will have been gathered and disposed of, leaving the house in possession of the Peaches and in as favourable condition as regards a successful crop as if this crop of flowers had not been produced. That complete success attends the working of this dual system is well shown by our illustration.

#### IN A LONDON GARDEN.

As a rule, London gardens are not pleasant to look upon in the autumn time, and principally, I think, because they lack that variety of flowering plants which is so essential to the good looks of a garden throughout spring, summer, and autumn. But few gardens in town, and none too many in the country, can really lay claim to the possession either of interest or beauty during all the seasons just named, although, thanks to the excellent teaching of gardening books and *THE GARDEN*, owners of gardens are daily becoming more cognisant of the fact that a wealth of flowers may be produced through many months from a comparatively small plot. Most London gardens are at their best during the spring months, many during the summer, and a few in the autumn. The reason of these metropolitan and suburban gardens wearing their brightest apparel so early in the year instead of awaiting brighter and warmer weather, as they naturally should do, is I think due to the fact that practically all their beauty is obtained from bulbous plants. And the reason is obvious, for bulbs, the commoner ones at least, need but very little attention at the hands of the gardener. Once well planted, their brilliant flowers stud the bare cold earth unfailingly as spring time comes round. To keep the garden attractive during summer time requires the expenditure of considerably more care and forethought. To say nothing of the labour of watering, staking, tying, weeding, &c., there is the periodical thinning out and regulating of the herbaceous perennials, sowing the seed of annuals and biennials, taking the cuttings of this and layering that, the proper

performance of which necessitates the expenditure of much more time than is often available. Of the best plants to make use of for keeping their gardens bright during the autumn months many are still ignorant. Thus the suburban garden generally speaking is at its best in spring, often untidy and overgrown in the summer months, and bare and devoid of interest in the autumn.

Recently I had the opportunity of seeing a London garden that could, however, neither be called uninteresting nor unbeautiful. The Hollyhocks, that once had towered so high as to peep into the neighbouring garden, now show signs of age in their yellow leaves, drooping stems, and fading flowers. Curiously enough some of the bright red singles are still in blossom, while no traces of the double flowered ones remain. Is it that the single blooms of the Hollyhocks last longer than the double ones, especially in a wet season like the present, or do the flowers continue to appear for a longer period? I think there probably is some foundation for the first suggestion, for the close double blooms would be much more likely to decay in a wet cold summer such as we have had than single ones. There are two white Phloxes still beautifully in flower which can be faithfully recommended to the suburban gardener, namely, James McKay and Virgo Marie. The former is a good grower and flowers for a considerable time. The inflorescence is loose and somewhat pyramidal, the flowers are white, with faint streaks of purple in the throat. The variety Virgo Marie also grows well and bears a more compact head of shapely flowers, whose broad petals are of good substance and a good white. Small groups of Sedum spectabile provide welcome colour here and there; it is not by any means a brilliant colour, but the large, somewhat dull red flower heads are not to be despised so late in the season. Even *Lilium speciosum rubrum* is not yet quite out of flower, although many of the Michaelmas Daisies are now but masses of brown. Their season this year seems to have been exceptionally short, due probably to the excessive rainfall. They have borne myriads of flowers, and these were so thick together that the decay caused by the wet very quickly spread and ruined them. Some of the Sunflowers also are over, but *Helianthus multiflorus*, maximus, and one or two more still brave the autumn winds. The only Golden Rods now left are *Solidago caesia robusta* and a dwarf form which bears the name of *S. multiradiata nana*.

## MISCELLANEOUS.

### MARKET FLOWERS AND FRUIT.

#### DAFFODILS AND PEACHES.

In the illustration we give of the early spring aspect of one of the many large Peach houses in one of our great market nurseries the many-sidedness of the horticultural industry is interestingly shown. Those who have had the privilege of visiting this well-known and successful home of fruit and flowers in early and mid-summer have no need to be told of the splendid crops of Peaches and Nectarines annually produced for the London markets in these capacious houses. What is less known, perhaps, is the fact that these same houses are made to produce another successful and remunerative crop every year, and that without any detriment whatever to the more important and permanent occupants of the houses, viz., the Peaches. The owner of these houses is an enthusiastic cultivator of the Narcissus (as he is, in fact, of everything he takes in hand), and has gathered together one of the best

The large and striking flowers of Pyrethrum *uliginosum* are still well in evidence; this year they have been particularly assertive, for the summer rains have had the effect of adding several inches to the normal height of this plant. The early-flowering Chrysanthemums are a great boon to the gardener who delights to have his garden presentable throughout the autumn; they provide a variety and wealth of colour, whose value cannot be over estimated. Notwithstanding that practically all the Roses in this London garden are Hybrid Perpetuals there is quite a respectable display of autumn flowers. Most beautiful of all them is Marie van Houtte, one of the very few Tea Roses grown here. It is represented by a single plant, but this has continued to produce blooms for the past three months at least, and still bears several exquisite creamy white flowers whose beauty is appreciably increased by the lovely and varied colouring of the outer petals. Crown Prince proves to be well worthy of being classed as an autumn bloomer, for even now it carries several large red flowers, deliciously scented. Maurice Bernardin, beautiful dark red; La France, Comtesse de Ludre, rose coloured; Augustine Guinoiseau, and Sultan of Zanzibar, whose later flowers are rosy red, are other Roses of much value to the London gardener in the autumn.

A. P. H.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

## CARNATIONS AND PICOTÉES.

[To THE EDITOR OF "THE GARDEN."]

**S**IR,—What Mr. Molyneux writes in your issue of the 27th ult. on the subject of border Carnations is very interesting. The varieties he mentioned were all raised at Hayes. I wish to point out, without detracting in any way from the merits of those he mentions, that there are in existence other raisers who put into cultivation good Carnations.

To turn to the subject of Carnation shows, so long as the disgraceful "faking" of the flowers—or what is called "dressing"—is permitted, and even encouraged, no good can possibly arise from them, as an entirely false impression of what the flower really is created. In many cases the entire centre of the flower is first removed and the calyx torn down to the stalk, the collar of card being then adjusted. The petals are arranged symmetrically by the aid of tweezers, and this is termed a flower, and is approved of by the judges and gains good prizes: in short, it is useless to exhibit blooms at first-class shows, in the boxed classes, unless they are treated in this barbarous manner.

If the chairman of the National Carnation Society—who we all know has the interest of the Carnation thoroughly at heart—would only put his foot down and say that for the future such practices should no longer exist, he would be conferring the greatest boon on true lovers of the Carnation and all those who do not use this most beautiful of all flowers as a simple counter for the purpose of getting money prizes. And it could be done. Why not? The cutting off of terriers' tails and the cropping of their ears died hard, but these barbarities, like the mutilation of these flowers, can be and should be stamped out.

In America Carnations are improving annually, and some of the finest winter-flowering varieties come from there now. True, their standard is not exactly our standard; but, apart from their fringed edge petals, they are all richly scented, and are far superior as regards size, length and soundness of calyx, and length and strength of stalk to anything that is grown in this country during winter. Our cousins do not tear their flowers to pieces, but they exhibit them as grown. They are put up in specimen glasses, so many of each variety, open as the day, where the stalk, calyx, and form of bloom

can be thoroughly examined before and behind, and such things as wire and tweezers are unknown.

By this means, which I submit is the only way, anyone can clearly see for themselves what a Carnation really is as Providence intended it should be, and not a mangled remnant, as represented at our shows of the present day.

There are several Carnations now in cultivation which are only fit for exhibition and shows under the present circumstances, in that they look all right when dressed on a card, having large blooms and a striking appearance; but if the visitor has the curiosity to examine the other side of the card he will find, in most instances, it has a badly split calyx, and that the stalk is wired right up to the bloom to make it hold its heavy head straight up. This state of things is all wrong, and if Mr. Martin Smith would only show his disapproval by bashing all "faked" flowers from the tables, and introduce the American system, in at any rate some modified form at first, he would be conferring a real boon upon all lovers of Carnations.

I will now add a few remarks to what Mr. Molyneux says about varieties.

### SELF CARNATIONS.

*White.*—What has Mrs. Eric Hambro done that it should not be mentioned in the first flight? I do not know any white that is more perfect and refined in every way than this.

*Red and scarlet.*—There is The Sirdar (Charington) and Isinglass (Salter), both excellent in these colours, and I do not think any of the newer dark varieties named are an improvement upon poor old Dodwell's Uncle Tom.

*Pinks.*—Ibis (Douglas), The Major (Spurling), and Little Dorrit (Chaudy) are all good.

*Yellows.*—Miss Audry Campbell is very well, but what has yet beaten the old Germania (Benay)? I have been growing a variety called Lord Roberts, which I have found very satisfactory. Then there is Miss Alley (Campbell) and Golden Fleece (Chaudy).

*Lavender and heliotrope.*—I had the honour of sending out Garville Gem, raised by Williams, and I differ from your correspondent as to Lady Jane Gray being superior. I have seen two or three that are better, but they are not yet in commerce.

### YELLOW GROUND PICOTÉES.

Childe Harold was challenged this year by The Pilgrim (Mathias), and badly beaten on several occasions. Mr. C. H. Herbert, the well-known Carnation authority, of the Sparkhill Nurseries, Birmingham, writes me: "I am very pleased with The Pilgrim you sent me last season: the flower I consider is better than Childe Harold, being a fuller flower and the petals flatter." Lauzan is good, but I cannot say I like the colouring, and there are several sent out lately that are more pleasing, such as Royalist (Douglas), Mrs. Herbert (Herbert), and some excellent varieties from Mr. Chaudy of Oxford.

### FANCIES.

Duchess of Roxburgh (Gow) is a very good yellow ground, a fine strong grower, and an all-round satisfactory flower. C. R. Thomson and Mrs. Curbstone (Herbert) are both beautiful fancies, besides several others, which, as they are of my own raising, I say nothing about.

Seedling growing is very interesting. I have been for some years occupied in hybridising certain varieties with the hope of some day raising a blue Carnation.

A new Carnation grower, whose catalogue will appear next year, would not be denied, and carried off all my stock. I have, however, reserved to myself an interest should the long hoped-for result be attained.

Planting of all Carnations that are to stand out of doors should be done instantly.

### SEED SUPPLY.

The supply of seed this season will be very short, owing to the cold summer and absence of sun. I do not know what the result has been in the Northern and Midland counties, but we in the

South are short by about 75 per cent. of our ordinary supply.

The new group of large self-coloured Tree Carnations, about which an article was published in THE GARDEN on July 26, are now safely housed at Welbeck Abbey, the entire stock having been purchased by her Grace the Duchess of Portland.

Dawlish, Devon.

H. W. WEGELEIN.

## THE BEAUTY OF GROUPING.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—There must always be happy disagreements in whatever pursuits one may happen to follow, so that I am quite at a loss to understand why your correspondent "M. L. W." (page 220) heads her letter "Heretical Sentiments." Why should the opinions therein expressed be deemed heretical? In the introductory chapter to "Wood and Garden" wise words are written on this subject, which I will quote for the benefit of your correspondent. The passage to which I refer is as follows: "The scope of practical gardening covers a range of horticultural practice wide enough to give play to every variety of human taste. Some find their greatest pleasure in collecting as large a number as possible of all sorts of plants from all sources, others in collecting them themselves in their foreign homes, others in making rock gardens or ferneries, or peat gardens, or bog gardens, or gardens for conifers or for flowering shrubs, or special gardens of plants and trees with variegated or coloured leaves, or in the cultivation of some particular race or family of plants. Others may best like wide lawns with large trees, or wild gardening, or a quite formal garden, with trim hedge and walk, and terrace, and brilliant parterre, or a combination of several ways of gardening. And all (the italics are mine) are right and reasonable and enjoyable to their owners, and in some way or degree helpful to others." Is it not a fact that nine out of ten borders planted in mixture—regardless of any kind of plan—are usually failures? It is small wonder, then, that THE GARDEN has long deprecated the system of muddled planting which has spoilt so many gardens, and is also responsible for the loss of many a good plant and shrub. To some extent I sympathise with your correspondent's remarks as to the monotony of massing if carried too far. The temptation to make too much use of one special plant, so that the eye is tired by its frequent repetition, is a dangerous one. To avoid this the best plan seems to be to allot part of the garden to certain groups of plants, avoiding the use of these same plants elsewhere. This system has been adopted in many good gardens, both large and small, and with marked success. Much of the beauty and interest attaching to the lovely gardens at Madresfield Court is due to the carrying out of this same idea. Then there is another point to be considered whilst discussing this question of grouping plants. A complaint has recently been made that interest is being largely sacrificed to mere appearances. When Forbes Watson attacked the bedding system he complained that its greatest fault was its uninteresting character. "My chief accusation then is," he wrote, "that gardeners are teaching us to think too little about the plants individually, and to look at them chiefly as an assemblage of colours. It is difficult in those blooming masses to separate one from another—all produce so much the same sort of impression. The consequence is, people see the flowers on the beds without caring to know anything about them or even to ask their names. It was different in the older gardens, because there was variety there, the plants strongly contrasted with each other, and we were ever passing from the beautiful to the curious."

Now to my mind this accusation is to some extent applicable to gardeners of the present day. When a new plant makes its appearance we hear little about its individual beauty and a great deal about its effect in the garden. Is this because in the rush and scurry of the present day few of us can spare the time to closely study the beauty of the flower, much less the beauty of stem and leaf? And, by studying the effect that a plant will produce in the garden in preference to its indi-

vidual beauty, are we not sailing perilously near to what Forbes Watson rightly declaimed? Only the other day a well-known hardy plant nurseryman told me that at the present time a plant *must* be showy in the mass to sell. To those of us who love to treat our plants as living beings, to study the beauty of their form and outline, and to learn something of their structure, this cannot fail to be a matter for regret.

It often appears to me that people do not obtain pleasing effects with massing because they fail to grasp what it really means. Too often one sees blocks of colour placed in a disjointed manner the whole length of a border without an attempt at any scheme of colouring or use being made of the grand hardy or half-hardy foliage plants which we now have at our command, such as Yuccas, Cannas, Megaseas, Irises, and other plants with noble leafage. Thus one passes from one mass of splendour to another, till the eye is as wearied by the garishness as it used to be in the old days of bedding-out. One is often told that this is massing, but I take it as being very far from what has been taught of late in the pages of *THE GARDEN*. Miss Jekyll tells us in

"Wood and Garden" that her chief aim is to "try for beauty and harmony everywhere, and especially for harmony of colour." There seems not the slightest reason why those of us who wish to grow a variety of interesting plants cannot do the same. Both Kew and Bath botanic gardens are rich in plants of the most varied character, arranged, as far as possible, to show a wealth of beauty all the year round, and surely it is not too much to express a hope that even in the smallest gardens beauty and interest may ever go hand in hand.

ARTHUR R. GOODWIN.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I read "M. L. W.'s" and "H. W.'s" letters with great interest. The question must usually end in a compromise with those of us who own small gardens. While we make colour-effects the controlling consideration in our gardening generally, we can reserve one large bed for the flower which gives us so much pleasure and interest. This question is akin to another which has often perplexed me—at what point the increase in quantity of a particular plant ceases to mean an increase of pleasure. Of course, it depends upon the nature of the plant, the position, and other circumstances, so that no general answer is possible. In *THE GARDEN* of the 27th ult. M. Correvon speaks of *Primula cortusoides* as strong crimson. The plant I have known under this name is more pink than crimson. I was looking out eagerly for an article on the species of *Tulips*, for there are few plants more attractive, so I read with pleasure "E. J.'s" article of the 4th inst. Will he kindly say whether he takes these bulbs up every year? In *THE GARDEN* of the 11th inst. *Cistus algarvensis* is mentioned. If I am right in thinking that *Cistus algarvensis* and *C. formosus* are nearly alike, I should like Mr. Arnott to know that *C. formosus* is quite hardy here. There are several large bushes in this garden, and when in full bloom with forty or fifty flowers on each bush their beauty is striking indeed.

*Coed Efa, near Wrexham.*

#### HISTORY OF THE AMERICAN BEAUTY ROSE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In this year's April number of a splendidly illustrated paper, *Country Life in America*, there is a passage which in the main confirms Mr. Peter Barr's remarks upon the introduction of this Rose into American commerce. It runs as follows:—

"The famous American Beauty Rose is often said to have originated in (George) Bancroft's garden. The facts are these: In Bancroft's garden were several varieties lately imported from France. One had no label. This was much admired by a florist named George Field, who happened to be looking over the place in company with Bancroft's gardener. Field asked for a cutting. He got it. Field and his brother worked quietly away for several years until they had a big stock, and then they advertised their novelty as the American Beauty Rose. They are said to have made a small fortune out of the transaction. The American Beauty has since become the most famous of all sorts in the United States. Some time after Field and his brother introduced the American Beauty horticulturists began to investigate its origin, with the result that its proper name was found to be Mme. Ferdinand Jamin, the name it had in France before, and a plant of it had been sent to Bancroft's garden, where the label was lost. This variety is of no importance in France or in Europe. In fact, the American Beauty has become so much modified by American conditions that some think

collection of Roses in October. So many are now interested in autumn Roses that we give a complete list of the varieties in Messrs. Frank Cant's collection.

#### OCTOBER ROSES.

##### MESSRS. FRANK CANT AND CO.'S GOLD MEDAL EXHIBIT.

ON Tuesday, the 7th inst., at the meeting of the Royal Horticultural Society in the Drill Hall, Buckingham Gate, Messrs. Frank Cant and Co., Braiswick Rose Gardens, Colchester, were awarded a gold medal for an exceptionally beautiful collection of Roses, an illustration of which we are able to give. It was generally admitted to be the finest display of Roses ever seen at so late a date, and we believe that never before has a gold medal been awarded to a

noisseau, Mme. Falicot, Mme. Hoste, Mme. H. de Potworska, Mme. Louis Poncet, Mme. Pierre Cochet, Mme. René Gérard, Maman Cochet, Maria C. Reine d'Espagne, Marie van Houtte, Marquise de Vivens, Medea, Mrs. B. R. Cant, Muriel Grahame, Papillon, Princesse de Sagan, Raoul Chauvry, Rêve d'Or, Safrano, Souvenir de Catherine Guillot, Souvenir de Pierre Notting, Souvenir de Thérèse Levet, The Bride, White Maman Cochett, and William Allen Richardson.

#### DWARF POLYANTHA ROSES.

## SOCIETIES.

### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE sixteenth anniversary dinner was held at the Holborn Restaurant on Thursday, the 10th inst., Arthur W. Sutton, Esq., F.L.S., V.M.H., presiding. There was a record gathering, no less than 111 persons sitting down to dinner, and the occasion proved one of the most enjoyable in the history of the society. By the kindness of the chairman excellent instrumental music was discoursed during dinner by the Alexandra trio. Amongst those present we noticed Messrs. G. J. Ingram, James Hudson (treasurer), E. Sherwood, R. Dean, Dawkins, S. Mortimer, C. H. Curtis, A. J. Baker, George Gordon, J. Heal, and others. Telegrams regretting their absence were received from Messrs. Peter Kay and H. J. Cutbush.

After the loyal toasts had been proposed, and reference made to the donation from His Majesty the King to the fund for building the new horticultural hall, the chairman gave the toast of "The United Horticultural Benefit and Provident Society." Mr. Sutton said that he had read up the work of the society and could think of none doing better work or that was better managed. The speaker made special reference to the benevolent fund, pointing out that this helps members after they have been on the sick fund for twelve months, those who are over seventy years old, and also the widows and orphans of deceased members. The convalescent fund Mr. Sutton thought was also well worthy of support, but suggested that its funds should be more liberally disbursed. Now thirty-six years old, the society was prospering as it never had done before. Twenty years ago there were but 55 members, now the number is 974, and this it was hoped would be increased to 1,000 by the end of the year. Twenty years ago the invested funds were £6,800, to-day they were £20,000. Speaking of lapsed members, Mr. Sutton said those who are unable to continue payment do not lose their money. He also referred to the economical manner in which the society was managed, its great usefulness, and the fact that the committee were anxious to increase the number of honorary members from between 70 and 80 to 100 by the end of the year. Mr. Sutton concluded by sincerely commanding the toast he gave.

Mr. James Hudson, V.M.H., treasurer of the society, responded. He said the benefit fund was strong by reason of the subscriptions. The benevolent fund was not quite so satisfactory, because honorary members were not so correspondingly numerous as were the benefit members. The future of the society will be what gardeners make it; unless they help themselves they must not expect help from others. Mr. Hudson concluded by urging gardeners to join, and hoped the members would obtain other members.

Mr. C. H. Curtis, in proposing the "Honorary and Life Members," said the society wanted honorary members chiefly to advocate its claims and take a greater interest in it than they otherwise would do. The £20,000 they had invested represented rather more than £20 per member, thus placing them in an unique situation. Mr. Curtis suggested that presidents of local gardening societies should help all they could. In the absence of Mr. Herbert J. Cutbush, Mr. A. J. Baker briefly replied.

Mr. George Gordon, in proposing the toast of "The Chairman," referred to the very valuable help that Mr. Sutton gave to gardening institutions. Mr. Sutton, in replying, made lengthy reference to gardening and gardeners. He pointed out how ancient and honourable a calling that of the gardener is, and spoke of the gardens in Palestine, immortalised in Scripture. Of these Mr. Sutton was able to give interesting particulars, as he has had the pleasure of visiting them. The enabling influence of gardening was dwelt upon by the speaker, who concluded by hoping those present would take to heart the lessons that are to be learnt from gardening.

The toast of "The Visitors" was given by Mr. C. F. Harding, and responded to by Mr. Richard Dean. Mr. W. Woods gave "The Press," Mr. W. P. Thompson replying. Pleasant music (which was under the arrangement of Mr. W. Morris of the Gunterbury Gardens), excellent recitations, and a thought-reading séance given during the intervals between the speeches were much appreciated.

The following statement of the work and privileges of the society was presented by Mr. J. Hudson (treasurer) to the chairman (Mr. Arthur Sutton):—

"This society has been established for thirty-six years, its rules having been certified and passed on August 3, 1866. Like many other such institutions, its progress at first was slow. Thanks, however, to its friends and supporters, its merits were realised by some of those for whom it had been constituted, and for the past sixteen years there has been an uninterrupted run of prosperity. Twenty-one years ago—in 1881—the membership was only 58; in 1886 it was 177; in 1891 the number was 413; and in 1896, 639. At the last audit the numbers were 904 (end of 1901), but now there are 974 benefit members. The executive hope that the number at the close of this, the Coronation year, will amount to 1,000. The funds of the society have increased in a similar ratio. These in 1891 stood at £6,822; at the close of the last financial year the amount invested and in hand for current expenses were £19,056. At the present time they stand at £20,000 in the aggregate."

"Some of the large benefit societies have heaped up their funds in tens of thousands by the misfortunes of their lapsed members, yet have not so large an average sum per member. In these societies members who allow their subscriptions to lapse lose everything."

### THE BENEFIT FUND.

"It is entirely opposed to all reason that in a 'benefit society' any section of its members should profit by the misfortunes of others. It cannot possibly occur in our society. The 'United,' from its commencement, has credited to each member his proportion of the year's working. Thus,

some have now to their credit in the books of the society over £100, to which is added yearly 3 per cent. interest. Each member has to contribute his proportion towards the sick fund of the current year, after which the balance is placed to his own account. A yearly balance-sheet is issued to each member, so that he knows from year to year exactly what funds he has to his credit. And in the event of his decease, his nominee can know at a glance what that balance is. When a member reaches the age of seventy years he can withdraw his balance in one sum, or in smaller amounts. Lapsed members, i.e., members whose accounts have been closed through ceasing to pay their contributions, can obtain their balances upon attaining the age of sixty years, the sum paid to such being the amount standing to their credit when they became lapsed members."

### THE BENEVOLENT FUND.

is provided for by the contributions of life and honorary members, and by a small annual sum from each benefit member. This fund provides for all members after they have passed the age of seventy years. It also assists members in cases of accident or other peculiar forms of distress, and the widows of such members who die in needy circumstances. The committee appeal urgently for more honorary and life members, so that this fund may be increased in proportion to the number of benefit members. With 1,000 benefit members, the number of honorary and life members should be at least 100.

### THE CONVALESCENT FUND.

is a purely voluntary one on the part of the benefit members. It was instituted through the kindness, liberality, and business forethought of Mr. N. N. Sherwood. Its funds are devoted to assisting members by a grant, so that they can obtain a change of air during convalescence. In the case of young gardeners who may be in lodgings during sickness, it is an important aid to their recovery.

### THE MANAGEMENT FUND.

is directed to the working expenses of the society. During 1901, with 904 benefit members, it amounted to £163 14s. 10d., an average of about 3s. 7d. per member, towards which each member contributes annually the sum of 2s. 6d., the balance being made up from the interest of monies standing to the credit of the lapsed members, and by the proceeds from advertisements in the annual report.

"The committee considers that this society in a measure fulfills what has been often urged upon the community at large, viz., the provision of 'old-age pensions.' It is a self-help society, its rules being framed so that the utmost possible return may be made to every member belonging to it, and in proportion to the number of years each one has contributed. The secretary is always willing to supply any information as to scales of contribution, &c. The funds are invested in approved trustee stocks, which yield on an average about 3 per cent."

### LIVERPOOL ROOT SHOW.

THE thirteenth exhibition, under the auspices of the Farmers' Club, was held in a marquee in Great Nelson Street, Liverpool, on the 18th inst. The exhibits and entries quite upheld the high position of previous years, whilst a large number of visitors attended. As in former years, the Lord Mayor of Liverpool attended and opened the show. The Right Hon. the Earl of Derby, K.G., also accords it his warmest support. The exhibits were of a high standard in every department. The Potatoes generally are the main attraction, and they were conspicuous by the quantity and the very fine quality. Owing to the number of classes only the first prize awards can be given. Six tubers in all cases comprised a dish.

### POTATOES.

White early Kidney of certain varieties, Mr. J. Johnson, Early Sutton's Regent, Mr. J. R. Newton. Early white round of certain varieties, Mr. James Johnson, with small but clean specimens of Superb. White, second early Kidney, of selected sorts, Mr. James Johnson, with Cole's Favourite. White, second early round, of selected sorts, Mr. Thomas Percival, with Royal Standard. Early or second early, any other shape, Mr. Ben. Ashton, with Ideal. Snowdrop or Lord of the Isles, Mr. W. Mackrell, with the former. Reading Giants or Colossal, Mr. Edward Davies, with the latter. Sutton's Abundance, Mr. George Ashley. Sutton's Satisfaction, Mr. James Johnson, with large clean tubers. Up-to-date, twenty-nine entries, Mr. Thomas Reason.

Late Maincrop or Langworthy, Mr. Ben. Ashton, good form. Late Kidney, Mr. James Johnson, with large Excelsior. Late round, Mr. B. Bowen, with Zion House. Late, any other shape, Mr. James Johnson, with Scottish Triumph.

Red or coloured early or second early, Mr. Ben. Ashton, with Reading Russet. Red or coloured early or second early Kidney, Mr. Edward Davies, with clean Fearless Rose. Red or coloured late Kidney, or any other shape, except round, Mr. Thomas Reason, with Edgocote Purple. Red or coloured late round, Mr. E. H. Wood, for Purple Perfection. Heaviest old or new variety, Mr. James Smith.

### NEW VARIETIES.

Early or second early Kidney, Mr. James Johnson, with Parker's Seedling. Early or second early round, Mr. James Johnson, with Sunbeam. Late Kidney, Mr. Ben. Ashton, with Webb's Empire; a special award was given, the tubers were large and of fine form. Late round, Mr. James Johnson, with Victory.

Special prizes presented by Messrs. Sutton and Sons.—For three dishes chosen from selected kinds, Mr. James Johnson, with a fine lot of Abundance, Ideal, and Satisfaction, the two first named being given special awards. One dish, any variety, bearing Sutton's name, Mr. Edward Davies, with Satisfaction. Sutton's Reliance, Mr. Thomas Percival.

Special prizes presented by Messrs. E. Webb and Sons.—One dish from selected kinds, Mr. Ben. Ashton, Webb's Yeoman or Webb's Renown, Mr. Ben. Ashton, with the

latter. Kidney shape, of selected kinds, Mr. Edward Davies, with Webb's Motor. Late round, from selected kinds, Mr. John Haycox, with Goldfiner.

Special prizes by Messrs. Fidler and Sons.—For Charles Fidler, first prize, Fidler's diploma of merit and gold medal, Mr. John Wilson; Mr. James Needham second, diploma and silver medal.

Special prizes by Mr. W. L. Hutton.—Any new variety, Mr. J. R. Newton, first, with Edward VII.; second, Mr. S. Maddock, with Maddock's Excelsior.

Special prizes by Mr. W. Kerr.—Round, first, Mr. Ben. Ashton, with Enterprise.

Special prizes by Mr. John Niven.—Kerr's General Buller, first, Mr. James Johnson. One dish from selected kinds Mr. John Wilson, with Pioneer.

Special prizes by Mr. H. Middlehurst.—For three Gateacre Swedes, Mr. G. Argyle won the silver cup, with very fine roots. Many other vegetables were also shown.

### FRUIT.

Six culinary Apples, Mr. G. Faulkner, with Warner's King. Six dessert, Mr. W. Morgan, with Blenheim Orange. Six culinary Pears, Mr. J. Davies, with Uvedale St. Germain. Six dessert, Mr. Thomas Guy, with Marie Louise.

Special prizes.—Six culinary Apples, Mr. W. Mackrell, Warner's King. Six dessert Apples, same exhibitor, with Ribston Pippin. Six culinary Pears, Mr. W. Mackrell, with Pitmaston Duchess. Six dessert Pears, Mr. W. Mackrell, with Geurre Hardy. Any other dish of fruit, Mr. Ben. Ashton, first, with Muscat of Alexandria Grapes; Mr. Thomas Guy, second, with Peaches.

Mr. R. Webster, president, Mr. James Lunt, Halewood, and his stewards made most satisfactory arrangements.

### ROYAL HORTICULTURAL SOCIETY.

A SPECIAL meeting of the Floral Committee was held at Chiswick on the 13th inst., to further examine late flowering Michaelmas Daisies. Some excellent kinds were in flower, several obtaining awards of merit and others being highly commended. Present: Mr. W. Marshall (chairman), with Messrs. J. F. McLeod, C. Jeffries, C. Dixon, R. Dean, W. J. James, E. H. Jenkins, W. P. Thomson, and J. W. Barr. Awards of merit was given to the following kinds:—

*Aster Novi Belgii Ariadne*.—One of the most handsome in the entire collection, and as here grown forming a rather close pyramid, which is both densely and profusely flowered. The solitary blossoms are  $\frac{1}{2}$  inches across, and the colour a good pale blue. We regard this as one of the very finest October kinds. Height, 5 feet to 6 feet.

*Aster Novi Belgii Calliope*.—A showy and vigorous kind, growing about  $4\frac{1}{2}$  feet high, and with pale mauve flowers. Of good growth and free-flowering, the bushes were laden with blossoms rather more than  $1\frac{1}{2}$  inches across. These two varieties were shown by the Royal Horticultural Society.

*Aster Novi Belgii Elsie Perry*.—An excellent kind in every way, with medium-sized blossoms of a warm rose tint. Height, 4 feet to 5 feet, with strong branching habit, on which the well formed flowers are produced continuously. From Mr. Amos Perry, Winchmore Hill.

*Aster Novi Belgii Coombeshare Brightness*.—Those who are acquainted with the well-known A. N. B. Coombeshare will only need to be told that this is a great advance, hence its rather descriptive final name. It is about 4 feet high. It is of bushy and fairly compact habit, and its free-flowering is remarkable. Flowers, medium size, rosy pink in colour, and at their best in mid-October. From Mr. E. Beckett, Aldham House Gardens, Elstree, Herts.

*Aster Cordifolia*.—Despite the obvious cross-bred character of this kind, an item rendering it difficult to classify at sight, it is a free and pretty kind. It is probable that it may prove an almost intermediate between either Novi Belgii or levis and one of the cordifolius section. The rather conical habit inclines to the last named. The flowers are of the palest blue. Height, 4 feet. From Miss Willmott, Warley, Essex.

*Aster rinniens Delight*.—A charming variety, graceful, and beautiful. Height, 3 feet or so, nearly erect, pleasing elegant habit, and smothered with white rosy-edged blossoms of  $\frac{1}{2}$  inch diameter. From Mr. E. Beckett.

*Aster cordifolius elegans*.—This possesses all the merit of typical A. cordifolius, and is more elegant in growth. In common with all this set the blossoms are very numerous. It is nearly 5 feet high; the flowers are white, and tinted with very pale mauve, while the ever-varying white and reddish disc completes a very pretty picture. In dainty and elegant habit, with great freedom of blossoming, these cordifolius kinds are not excelled. From Messrs. Dobbs and Co., Rotheray, N.B.

*Aster acris var. nanus*.—The name here given is not only singularly appropriate, but, one may almost add, amply descriptive of one of the most charming things in the whole collection. It is really a dwarf form of A. acris, but comes into fullest beauty when the type is on the wane, thus being doubly useful. The starry blossoms are just as free as in the typical kind, and the linear leafage the same, but the height is barely 16 inches, as growing at Chiswick, a fact alone that is suggestive of the many uses to which it may be put. It is indeed a most welcome kind to be at its best in mid-October. Planted together with other acris varieties its true habit could be seen at a glance. From the Royal Horticultural Society.

The following were highly commended:—

*Aster Novi Belgii semi-pleno*.—This was labelled "as received, A. N. B. flore-pleno, but the committee were unanimous in the opinion that such a name would mislead, therefore the modified form as above was put forward. The variety is of quite a promising character, of very good habit, and producing the large pale blue blossoms in which a touch of lavender is also seen. Height, 5 feet. From Miss Willmott, Warley, Essex.

*Aster Novi Belgii Jessie Crum*.—This also came from Miss Willmott. Growing some  $4\frac{1}{2}$  feet high, and loaded as it is with a wealth of rosy lilac flowers, it is very bright and attractive even amid the host of good kinds here seen.

*Aster Novi Belgii Edna Mercia.*—The flowers of this are of medium size, and of rich rosy purple. They are well formed, and the habit and freedom of blooming all that could be desired. The plant is about 3½ feet high. Although seen in good condition at this meeting, the variety really belongs to a date fully a fortnight earlier. From Mr. Amos Perry, Winchmore Hill.

*Aster rimusus Freedom.*—This is only surpassed by A. V. Delight, yet the great array of its starry white yellow-eyed blossoms doubtless called forth a very serviceable name. Freedom has all the attributes of its type, and surpasses it in freedom of flowering. From Mr. E. Beckett.

*Aster cordifolius Ideal* is virtually an improved form, possibly a seedling of *A. c. Diana*, from which it differs only in the rather more deeply coloured flowers. The great mass of starry, delicately toned blossoms renders it one of the most pleasing varieties of *A. cordifolius*. It will assuredly meet with many admirers. From Mr. Beckett.

*Aster cordifolius Sweetheart.*—This exquisite variety has flowers of the palest, softest blue or pale lavender, a tinge so delicate that it is not easy to describe. The variety attains 4 feet to 5 feet high, and the firm, vigorous, freely branched growth and stems, lateral as well as principal, are just loaded with a mass of blossoms that would be dense but for the free branching character of the plant, which disposes of them in the most graceful fashion. It is a charming kind. From Mr. Amos Perry, Winchmore Hill.

*Aster Novae Angliae W. P. Bowman.*—This is one of the finest of the Novae Angliae group. Strong and vigorous, 5 feet or more high, it produces among the latest of these Aster's its large and handsome rosy purple flowers. These latter are in a shortly branched head, thus creating a good effect in a mass. The flowers are very richly coloured. From the Royal Horticultural Society.

#### ORCHID COMMITTEE.

Present: Messrs. Harry J. Veitch (chairman), James O'Brien, J. G. Fowler, H. Little, de B. Crawshaw, Norman C. Cookson, H. M. Pollett, James Douglas, Frank A. Rehder, N. F. Bilney, J. Charlesworth, F. W. Ashton, G. F. Moore, F. J. Thorne, W. Boxall, W. H. Young, W. H. White, H. A. Tracy, H. Ballantine, J. Wilson Potter, and F. Sander.

A small group of Orchids was shown by J. Bradshaw, Esq., The Grange, Southgate, N. (gardener, Mr. G. G. Whitelegge). It contained some excellent Cattleya labiata, *C. Lodigesii alba*, *C. Mantinii x nobilior*, *Oncidium Forbesii*, *Odontoglossum grande*, *Dendrobium nobile* Cooksoni, *C. John Baguley* (*C. bowringiana x C. hardiana*), and others. Silver Flora medal.

Messrs. Charlesworth and Co., Heaton, Bradford, Yorks, exhibited a group of Orchids, in which were several very choice plants, many of them hybrids. We noticed Cattleya Mrs. J. W. Whiteley (*C. bowringiana x C. massaiana*), a lovely flower; *C. Mrs. J. W. Whiteley magnifica*, with a larger, more brilliantly-coloured lip; *C. Iris*, *C. chamberlainiana* (*C. guttata Leopoldii x C. aurea*), *L.-C. gottoiana* (*C. Warneri x L. tenebrosa*), *L.-C. gottoiana superba*, Cypripedium Standard (*C. Charlesworthii x C. leeanum giganteum*), a very good crispum—*O. c. Trianae roseum*, with heavy spots of chocolate-red; *L.-C. Weedmansi Kuhleibii* (*C. granulosii x C. Mendelii*). There was also a well-flowered plant of *Ocicidium ornithorhynchum album*, and several other well-flowered and choice Orchids. Silver Flora medal.

Messrs. James Veitch and Sons, Limited, Chelsea, exhibited a small collection of Orchids, consisting chiefly of most beautiful Lelio-Cattleyas and hybrid Cattleyas. Particularly striking were *Lelia splendens* (*L. crispa x L. purpurata*), Cattleya *wendlandiana* (*C. bowringiana x C. Warscewiczii*), *C. Mantinii* (*C. bowringiana x C. dowiana aurea*), *L.-C. bletchleyensis* var. *urania*, *C. porphyroblepharia* (*C. superba x C. intermedia*), *C. x Chloris* (*C. maxima x bowringiana*), a striking flower of a blue-purple colour; Cypripedium Baron Schröder (*C. cananthum superbum x C. fairianum*). Silver Flora medal.

Messrs. Sander and Sons, St. Albans, exhibited a group of Orchids in which several good things were noticeable. *Vanda coerulea* was represented by two plants bearing splendid racemes of their uniquely beautiful flowers, Cattleya *Maroni* (*C. velutina x C. aurea*), Lelio-Cattleya *gottiana*, *L.-C. bowringiana* Clive (sepals and petals purple, lip an intense velvety purple, with two yellow blotches below the column), *L.-C. Euterpe aurea*, *L.-C. Martinette* (*C. Mossiae x L. tenebrosa*), *L.-C. bletchleyensis*, and others. Silver Banksian medal.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, showed several beautiful Orchids, notably *Oncidium ornithorhynchum album*, Cypripedium fansonii magnifica (C. Morganii x C. rothschildianum), Cattleya *area Rosita*, Lycaete hybrida Low's variety (a natural hybrid), Cattleya *Mantinii nobilior*, and others. Silver Banksian medal.

J. Gurney Fowler, Esq., Glebelands, South Woodford, showed a small group of choice Orchids, for instance Lelio-Cattleya *haroldiana superba*, *Lelia digbyana-purpurata*, var. King Edward VII. (a very handsome flower), *L.-C. bletchleyensis* Fowler's variety (described elsewhere), and others. Silver Banksian medal.

Walter C. Walker, Esq., Percy Lodge Garden, Winchmore Hill, N. (gardener, Mr. George Cragg), sent several pretty forms of *Odontoglossum crispum* and *Dendrobium schrederianum*. Silver Banksian medal.

H. J. Elwes, Esq., F.R.S., Colesbourne Park, Cheltenham (gardener, Mr. Walters), showed Habenaria carnea bearing two erect racemes of large pale pink flowers, and one still undeveloped. Cultural commendation. Stenoglottis longituba Colesbourne var. was also shown by Mr. Elwes.

Mr. James Douglas, Edenside, Great Bookham, Surrey, sent *L.-C. gottoiana Edenside* var.

Lelio-Cattleya Henry Greenwood was sent by Messrs. B. S. Williams and Son, Upper Holloway, N.

A cultural commendation was given to Sir Trevor Lawrence, Bart., Burford, Dorking (Orchid grower, Mr. W. H. White), for *Angraecum Kotschyii*, a plant bearing a drooping raceme of curious white flowers, furnished with long stalk-like tails fully 9 inches or 10 inches long.

A cultural commendation was given to F. Wellesley, Esq., Westhild, Woking, for a fine plant of *Cattleya Maroni* (*C. velutina x C. dowiana aurea*).

#### CERTIFICATE ORCHIDS.

*Odontoglossum harryano-crispum var. delicata.*—This is a remarkable variety of *O. spectabile* (*O. harryano-crispum*). The flower is large, the sepals and petals long, somewhat tapering, and prettily crinkled. Very pale green is the ground colour of the sepals, which are heavily spotted with chocolate-brown. The lower half of the petals is white, also spotted with brown, and the upper half is pale green. The large flat slightly receding lip is white, prettily marked with brown. Exhibited by Baron Schröder, The Dell, Egham (gardener, Mr. H. Ballantine). First-class certificate.

*Lelio-Cattleya bletchleyensis* *Fowler's variety.*—A remarkably handsome flower, large, and of most beautiful colouring. The petals are of a dark rose colour, and the sepals a lighter tone. The most remarkable attribute of the flower, however, lies in the vivid colouring of the lip. Practically all over, both inside and out, it is a rich crimson tinged with purple. The upper sepal and the petals are somewhat drooping. Shown by J. Gurney Fowler, Esq., Glebelands, South Woodford. First-class certificate.

*Lelio-Cattleya x Mrs. Chamberlain.*—The parents of this hybrid are given as *Cattleya choocoensis* and *Brassavola digbyana*, and a peculiarly pleasing flower has resulted from the cross. The large, beautifully fringed lip is pale lilac, with an exquisitely coloured throat—a pretty green. The loose sepals and petals are dull white very lightly tinged with lilac. From the Right Hon. Joseph Chamberlain, M.E., Highbury, Birmingham (Orchid grower, Mr. J. Mackay). Award of merit.

#### FRUIT AND VEGETABLE COMMITTEE.

Present: Messrs. George Bunnard (chairman), Henry Esling, S. Mortimer, A. Dean, W. Pope, Edwin Beckett, George Kelf, Horace J. Wright, J. Willard, J. Jaques, G. Reynolds, F. L. Lane, James Smith, G. Norman, James H. Veitch, George Wythes, and W. Ponpart.

Major Bythway, Warborough, Llanelli, South Wales (gardener, Mr. Walter Wilkins), obtained a silver-gilt Knightian medal for a collection of Apples. The cooking varieties were shown better than the dessert fruits; they were really excellent. All were well coloured, and many were of good size.

Mrs. Arnold, The Lodge, Dedham, showed a small collection of Apples. Bronze Banksian medal.

Leopold de Rothschild, Esq., Gunnersbury House, Acton (gardener, Mr. J. Hudson), was given a cultural commendation for autumn fruiting Raspberry *Belle de Fontenay*.

Mr. W. Shrigley, head gardener to Lord Hastings, Melton Constable, showed a new Grape, Melton Constable Seedling, the result of a cross between the varieties the Lady Hastings and Gros Colman. Pot Vines were shown bearing four or five bunches; these were of medium size. The berries were a good colour and carrying an excellent bloom. The flavour of this new Grape, however, did not recommend it to the committee.

Mr. George Bunnard, Royal Nurseries, Maidstone, showed fruits of Burbank's Giant Prune.

Several other new fruits were shown, but only one award was made.

R. W. Hudson, Esq., Danesfield Gardens, Bucks (gardener, Mr. J. Gibson), obtained a gold medal for a very fine collection of vegetables. The exhibit was splendidly set up, quite one of the best arranged collections we have seen. A great number of dishes were included, and the quality was all that could be desired. The background of the exhibit consisted of Cabbages, Cauliflowers, Brussels Sprouts, Celery, Leeks, &c., the smaller dishes being arranged in front. Such displays as this are worthy of great praise. Nothing does more to foster an enthusiasm for vegetable culture than a representative display of first-rate produce, such as Mr. Gibson's exhibit undoubtedly was.

Messrs. Cannell and Sons, Swanley, Kent, were awarded a silver Knightian medal for an interesting miscellaneous collection of vegetables. They were well grown specimens, and bore good testimony to the Kentish soil and Mr. Cannell's skilful culture.

Mr. John Crook, Forde Abbey Gardens, Chard, sent a dish of Green Peas (Veitch's Gladiator), also some foliage to show the good effect of spraying, to keep down mildew and thrip, with Messrs. White's Sprayer.

#### NEW FRUIT.

*Apple Edward's Coronation.*—An award of merit was given to this new Apple, whose parentage was not communicated, but we should say that Cox's Orange Pippin is undoubtedly one of the parents. It is flatter than Cox's Orange, prettily coloured on the sunny side, and the stalk is long and thin. The flavour is excellent. It is said of the tree that it is of compact habit and a good grower. Shown by the Hon. H. B. Portman, Buxted Park, Uckfield (gardener, Mr. H. C. Prince).

#### FLORAL COMMITTEE.

Present: Mr. W. Marshall (chairman), and Messrs. C. T. Drury, H. B. May, Jas. Walker, R. Dean, J. F. McLeod, W. Howe, R. W. Wallace, Chas. Dixon, W. Bain, Chas. Jeffries, H. J. Cutbush, Chas. E. Pearson, Geo. Gordon, C. E. Shea, H. J. Jones, E. H. Jenkins, W. P. Thouson, J. H. Pitt, Geo. Paul, and J. Fraser.

In every direction the fast approaching winter season was made apparent, hardy plants and Dahlias are being replaced by Chrysanthemums, of which there were good collections shown. Some few groups of hardy plants still remained, and of these Messrs. Barr and Sons, Covent Garden, contributed a most interesting lot. The Michaelmas Daisies were in plenty, and of these we select one which we consider should be in every collection—*Novi Belgii* Mrs. W. Marshall. It is a fine plant, and we do not remember to have seen the variety before. Some few Phloxes were good, and especially so the Kniphofias, such as *Triumph*, *Leichtlini distachya*, of a red-flame tone, *Corallina superba*, very brilliant in colour, &c. Gladioli were strong, and the

*Childsii* forms very beautiful. A charming lot of autumn Crocuses included *C. speciosus*, *C. zonatus*, *C. pulchellus*, a set of gems not to be equalled by any other three, while of *Colchicum*, the double white and pink were good. *Cactus Dahlia*, *Pentstemons*, some few *Lilium auratum*, the pretty *Polygonum molle*, with fragrant white plumes, were other things of interest, and not less so the pink Japanese *Anemone Queen Charlotte*, a large and handsome kind that will quite displace *A. j. elegans*. Early Chrysanthemums and other plants completed quite a good lot of things. Bronze Banksian medal.

Messrs. T. S. Ware, Limited, Feltham, also had hardy flowers, and here again many things of like character found a place. *Cactus Dahlia* were very good for so late a date, at once revealing the open character of the season, when such as *Vesta*, *Island Queen*, *Zollern*, *Starfish*, *Innovation*, and others were quite characteristic. *Lilium speciosum* in variety, *L. auratum*, *Pentstemons*, Early Chrysanthemums, *Asters*, *Sunflowers*, and Japanese Anemones were all good. *Kniphofia Nelsoni* was very fine; so too, *Amaryllis Belladonna*, and a pretty lot of *Nerines*, most of them seedlings. The gold and silver-leaved Cornish Moneywort (*Stibthoria*) were also shown. Bronze Banksian medal.

From Edmonton, Messrs. J. Hill and Sons brought some fifty species and varieties of Polypodiums, in which the well-known kinds *glaucum* and *anreum* were in conspicuous contrast with *vaccinifolium album*, *pectinata*, *piloselloides*, *musifolium*, and others. The entire lot were excellent and well-grown examples. Silver Flora medal.

Mr. John Russell of Richmond showed a table of *Aucuba vera*, perfect bushes, freely set with brilliant red berries and the plants about 9 inches above the pot. Nothing could be better than such as these for ornamental use as pot plants, for which their perfect hardiness would stand them in good stead. There must have been some two hundred plants or so. *Osmanthus purpureus* was also shown. Bronze Banksian medal.

Messrs. J. Peed and Son, Norwood, showed *Dracanas* and *Cratons* in variety, together with *Begonia Gloire de Lorraine* and a few *Cypripediums*, *C. Medea*, *C. calophyllum*, &c., the variegated *Ficus*, *Anthuriums*, and the like. Vote of thanks.

Messrs. James Veitch and Sons, Limited, Chelsea, set up a grand table of their new winter-flowering Begonias, in which Mrs. Heal and the wonderfully free-flowering *Idealas* were the main features. *B. Incomparabilis*, derived from crossing *B. Freebilly* and *B. polystylis*, is also a remarkable hybrid, superior to either parent from the decorative standpoint. The set represents a great advance in *Begonia* hybridisation. *Daedalanthus parvus* has deep violet-blue flowers upon quite dwarf plants, and by these a group of *Javanico-jasminoides* Rhododendrons was shown. Silver Flora medal.

Mr. G. Shawyer, Hounslow, showed several good Chrysanthemums mostly seedlings. *Eleanor*, fine white; *Miss B. Miller*, orange-yellow; and *Black Prince*, being of the best of those named.

H. J. Elwes, Esq., Cirencester, Gloucestershire (gardener, Mr. Walters), showed an admirable lot of *Nerines*, *Mrs. Harrison*, red crimson; *Miss Carrington*, deep rose-pink; and *Rosebud*, being remarkable, the last the most distinct of all both in form and colour. This at least should prove a good breeder by reason of its widely distinct character generally. For the remainder we can only say they represent an admirable lot of these charming plants. Silver Banksian medal.

The white and typical form of *Begonia Gloire de Lorraine* were set up by Hugh Kerr, Esq., South Woodford (gardener, Mr. Dunkley), the large and bushy plants being freely flowered.

Messrs. William Bull and Sons, Chelsea, had tree Ferns, *Dicksonia glauca*, *D. antarctica*, *Cibotium species*, *Cyathaea medularis*, &c., large handsome heads on fine stems. Silver Banksian medal.

A noteworthy group of *Adiantum Farleyense* with *Dracanas* came from Mr. H. B. May, Edmonton, all beautifully grown stuff, as is his wont. The *Dracanas* were grouped and contained such kinds as *His Majesty*, *Warreni*, *Miya*, *Bergmanni*, &c., and with a few graceful Palms made a very pleasing and fresh-looking group. Tree Carnation *Triumphans*, a scarlet kind, dwarf and very free, was also shown. Silver Flora medal.

Mrs. Dennis, Little Gaddesden, Berkhamsted (gardener Mr. Gentle), set up an assortment of Michaelmas Daisies in well-known kinds mostly, together with seedlings.

Messrs. Cannell and Sons, Swanley, contributed Chrysanthemums, in which Lord Ilipetou (crimson and gold), *Mrs. Harry Emerton* (yellow), and *Princess Henry* (a hirsute kind) were the most notable. Many early-flowering sorts were also staged. Silver Banksian medal.

A large white-flowered Chrysanthemum, *Laura Howard*, was exhibited by Mr. W. Howard, Shanklin, Isle of Wight.

Messrs. E. S. Williams and Son, Holloway, staged a group of *Dracanas*, fine well-grown examples in good kinds, such as *Gladstone*, *amabilis*, *Alsace Lorraine*, *Baptistii*, *Emile Zola*, *Imperialis*, &c., with the beautiful yellow *Allamanda Williamson* in the midst.

Messrs. Cutbush and Son, Highgate, had a large as well as comprehensive group, in which there were Michaelmas Daisies galore, artistically set up, and in not a few of the best kinds; for example, *cordifolius*, *Diana*, and *elegans* were very beautiful, while one called *Captivation*, rose-pink in colour, was very pretty. *Amellus Stella*, a quite starry kind; and *Enchantress*, a fine pyramid of palest mauve, were both good among these popular kinds. Then in Tree Carnations we noted the white *Mrs. Brooks*, the crimson *Malmaison Maggie Hodgeson*, the white and striped Sir *Hector Macdonald*, and the crimson *General Maceo*. A silver Flora medal was awarded.

In the group of Chrysanthemums from Mr. Wells, Redhill, the following varieties were prominent: *Lord Alverstone*, rich crimson, broad florets, with light gold reverse, very handsome; *Mrs. T. W. Pockett*, yellow, very fine, but rather paler than usual; *Mrs. J. T. Thorncroft*, bronze and yellow; *Miss E. Fulton*, white, very fine; *Phyllis*, orange-yellow;

gold; Mme. Gustave Henry, white; Mme. Von André, yellow, of canary tone, &c. Then around the front was a margin of such as Jules Mary, Carrie, Gertie, and many others of the free-flowering class that grow so well in the open ground. The group was an admirable one, well staged, and the flowers fresh looking and tempting. The silver-gilt Flora medal was well merited.

In that from Mr. H. J. Jones we saw such excellent examples as are rarely seen at these early meetings. The best things in this fine group were Mrs. C. Brooks, white, very fine quality; Mrs. James Mileham, rose-mauve, with silvery reverse, was in splendid form in several places and everywhere good in this group. It is a massive and well-built flower, and fully big enough to satisfy the big flower champions of the day. Mrs. Greenfield, gold; Godfrey's Pride; Lady Audrey Butler, yellow; Miss A. Byron, white; Bronze Soleil d'Octobre, Godfrey's Triumph, M. Paoli Radelli, pure white, &c. In this group, too, were many Palms, graceful Phoenix drooping over the flowers, while a margin of early kinds and a fringe of Asparagus Sprengeri completed as fine a lot as we have seen at any October meeting. There were, indeed, many superb blossoms. Silver-gilt Flora medal.

Some good cut Chrysanthemums were shown by Miss Edith Somers, Bushey (gardener, Mr. Cooper), Mme. Gustave Henry, Hairy Wonder, and Bouquet de Dame being the best.

A similar lot was sent from the Hon. W. F. D. Smith, M.P., Henley-on-Thames (gardener, Mr. Perkins), Lady Ackland (gold), Primrose Dame (yellow), and Mary Perkins (rich yellow) being noted.

*Begonia* Mrs. D. C. Guthrie is a rose-pink kind, from D. C. Guthrie, Esq., East Haddon Hall, Northamptonshire (gardener, Mr. H. Trueman). This was stated to be a sport from B. Gloire de Lorraine, but there was no evidence of this. The plant also is strongly tuberous.

*Nerine* coruscans major in fine trusses came from H. J. Lane, Esq., Bexley, Kent, and was much admired.

Mr. W. J. Godfrey, Exmouth, set up a sterling lot of Chrysanthemums of several sections, though notably show kinds, in which he is evidently very strong. For instance, Loveliness (soft yellow), Sensation (bronze and gold), Kimberley (rich gold), Lord Alverstone (crimson, with gold reverse, very fine), Masterpiece and Grandeur (both of the red-crimson type), Exmouth Rival (a superbly dark kind, with finely finished petal, almost velvet-like), and Queen Alexandra (buff-orange) were all good things. Free-flowering decorative kinds were also included, of which October King, Mars, and Pink Beauty were noted in particular. In addition there was a group of Tree Carnation Exmouth Pink, a flower of pleasing shade and rather full. Some others were shown, but no names were to be given. Silver Flora medal.

The following obtained awards of merit:

*Chrysanthemum* Miss E. Fulton.—A fine kind of the incurved type of Japanese, with broad and massive florets of a fine pure white. From Messrs. Wells and Co., Redhill, Surrey.

*Chrysanthemum* Hon. Mrs. Ackland.—A rich golden yellow, fine in build and superb in colour. From the Hon. W. F. D. Smith, M.P., Henley-on-Thames (gardener, Mr. Perkins).

*Chrysanthemum* Mme. Paoli Radelli.—As shown, this massive flower, of the largest size, was of a soft pink tone, whiter near the centre, or rather less coloured at the tips. Other flowers in the Hall appeared white, we believe. The above was shown in capital condition by Mr. Norman Davis, Framfield, Sussex.

*Anemone japonica Queen Charlotte*.—A pink flowered kind of increased size and beauty, and certainly a most meritorious variety worthy of free planting. From Messrs. Barr and Sons, Covent Garden.

*Cinicutigia japonica*.—This is said to be equivalent to C. simplex. It is the purest kind known, and the most late in flowering. Flowers are produced in dense columnar spikes from amid much divided leafage. Flowers pure white. Shown by Leopold de Rothschild, Gunnersbury House, Acton (gardener, Mr. Hudson).

*Nerine* Miss Carrington.—Flowers of a deep rose-pink, large, with much undulated segments, spikes bold and freely flowered. From Mr. H. J. Elwes, Cirencester (gardener, Mr. Walters).

A botanical certificate was awarded to *Nerine flexuosa alba* from Messrs. Barr and Sons. The plant is taller than the type, and flowers in company with good arching leaves.

#### THE LECTURE.

#### "SUMMER AND AUTUMN BULBS."

Mr. P. R. Barr, in his paper on the above subject, gave much interesting and valuable information concerning the best bulbs for summer and autumn. The word "bulb" was taken in its broadest sense, so as to include corms, tubers, &c. Ranunculi were first mentioned. These, said Mr. Barr, should be planted 2 inches below the ground. The beauty and value of the Spanish and English Irises was extolled, and the best varieties given. They were said to be amongst the easiest of bulbs to cultivate, September planting giving the best results. Ixias, Calochorti, and Sparaxis were next brought to notice. Ixias like a sunny spot and well-drained soil. The Sparaxis, which require similar culture, are most brilliantly coloured flowers. The Calochorti were one of the gems of June flowers. They are the sole representative of the Tulip family in the Western Hemisphere. The different sections, all of which are hardy, were described. The early Gladioli were very valuable, G. byzantinus and G. Colvillii being very suitable for naturalising. Plant 4 inches or 5 inches deep from October to January in a situation protected from the wind. Many Lilliums were mentioned, and these, said Mr. Barr, are best left undisturbed. They like a cool rooting medium and a well-drained soil.

The Alstroemerias are good border flowers for July, and with the exception of A. peregrina and A. pulchella may be considered hardy. They are invaluable for cutting. In August we have Gladioli, Tigridias, and Montbretias. We are much indebted to M. Lemoine, of Nancy, for his work

with the Gladioli, said Mr. Barr. From the middle of March to the end of April is the best time to plant Gladioli. The Lilies for August include L. auratum and varieties and the Tiger Lilies. The Tigridias were lovely flowers. They were of easy culture. Plant in March or April. The bulbs should be lifted in the autumn and stored during winter away from frost. In September, Lilium speciosum and Amaryllis Bella-donna are at their best. The last-named should be planted at the foot of a south wall, as also should Vallota purpurea. Mr. Barr concluded his essay with a reference to the beauty of autumn Crocuses, the best sorts being given. If the bulbs are planted in July they will flower the same season.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the floral committee was held at the Royal Aquarium, Westminster, on Monday afternoon last, at three o'clock, Mr. D. B. Crane in the chair. There was a good attendance of members, and many novelties were submitted for their adjudication. The new rule, which requires the support of three-fourths the members present to grant a first-class certificate to any novelty, is having the effect of making it difficult to gain the coveted distinction, and on this account awards by the floral committee from this time forth should therefore be held in high esteem. The only variety, and this a Japanese, to obtain a first-class certificate was

Mme. Paoli Radelli.—This is an immense incurved Japanese bloom of splendid form and capital substance. The florets are very long and fairly broad, neatly curling and incurving at the ends, and building up a very deep flower. Colour, pale rosy blush tinted yellow in the centre. From Mr. Norman Davis, Framfield, Sussex.

The following variety was commended for its colour:—

*Exmouth Rival*.—A Japanese bloom of medium size with fairly broad florets of medium length, and somewhat pointed, developing a flower of neat and even form. Colour very deep rich crimson with bronze reverse. This is a bloom of which much may be heard later. From Mr. W. J. Godfrey, Exmouth, Devon.

The committee expressed a wish to see the following varieties again:—

*Mabel*.—A large loosely built Japanese flower of drooping form, and fairly broad florets of great length. Colour suffused and edged rose, reminding one of Belle Paulle. *Hon. Mrs. A. Ackland*.—A lovely Japanese bloom of even and pleasing form, with broad florets reflexing, and incurving at the ends. The colour is a lovely rich and deep shade of yellow, somewhat approaching the tone of yellow as seen in R. Hooper Pearson, a very promising novelty. *Duke of Devonshire*.—A large spreading flower with long and fairly broad florets curling and twisting. Colour, a distinct shade of yellow, paling at the ends of the florets, and tinted rosy red. A vote of thanks was accorded Mr. M. Silsby, Shanklin, Isle of Wight, for a single bloom of a very handsome Japanese seedling named *Mrs. F. W. Wallis*. This is a large flower with long drooping and broad florets, which build an enormous exhibition specimen, of good form. The colour is deep yellow, striped and suffused reddish crimson.

On Monday evening last the executive committee held a meeting at the Royal Aquarium, Mr. Thomas Bevan presiding. Arising out of the correspondence was a discussion as to the forthcoming Chrysanthemum show at Chicago, which is being organised by the American Chrysanthemum Society, and a letter was read from the secretary. It was announced that every effort was being made for a most successful show, that classes had been instituted for English and French varieties, that a conference would be held, and that the American society would be pleased to see blooms sent over by European growers if any could be induced to do so. Much interest was evinced in the announcement, and there was an evident desire on the part of the committee to express practical sympathy with the American show, but in the present state of things it was decided to defer matters until next year, when the National Chrysanthemum Society's budget might more safely justify some substantial recognition of the sister society's efforts. There is some probability that next year the show will be held at New York.

Owing to the absence of the president (Sir Albert Rollitt), it was resolved that the annual dinner be postponed to suit his convenience. Prize money awarded at the October show amounted to £66 3s. 6d., the amount in Mr. Deverill's classes being in addition. A list of the medals awarded to miscellaneous plants was also read.

An interim financial statement was read by the secretary, and owing to the sale of the Royal Aquarium it was resolved that the sites committee should determine on a place for the annual general meeting.

The secretary of the catalogue committee stated that he hoped the MS. would shortly be in the printer's hands, but the work had been unexpectedly heavy.

Twelve new members were elected, and the Seabrook, Ilythe, and Sandgate Mutual Improvement Society received in affiliation.

#### THE HORTICULTURAL CLUB.

AFTER the usual summer recess this club resumed its annual series of dinners at the Hotel Windsor on Tuesday, the 21st, this time under the chairmanship of its president, Sir John Llewellyn, Bart., and with an attendance of some thirty members and friends. Prior to the summer the usual business of the club was disposed of, which embraced a contribution of twenty guineas to the Royal Horticultural Society's hall, plans and elevations of which were exhibited by the Rev. W. Wilks. Since the last meeting in June the club has to lament the deaths of two of its esteemed members, Mr. R. Goffon Salmon and Mr. Edward J. Cockett, to whose families it was resolved to send letters of condolence. After dinner, in accordance with the custom of the club, a paper was read by Mr. T. Alfred Rivers on "Pot Fruit Trees for Amateurs," and it need hardly be said that, coming as it did from the ruling representative of the third generation of a family to whom so much is owing by

the world as regards fruit culture and its improvements, the paper in question was of unusual value. Mr. Rivers demonstrated by the record of his experience that good crops of Apples, Pears, Plums, Cherries, Peaches, Nectarines, and even Apricots can be obtained under those quite cold conditions of culture which appeal more to amateur capabilities, and there is no doubt but that the paper and the subsequent discussion it evoked are admirably calculated to foster such cultivation wherever greenhouse space is available. At the conclusion of the paper an animated discussion followed, conducted by such well recognised authorities as Messrs. Bunyard, Hudson, G. Paul, Owen Thomas, Walker, Pearson, and Veitch, and the Revs. W. Wilks and G. Engleheart, whose remarks considerably enlarged the purview of the paper and enhanced the value of the initial points contained therein.

The question of repotting was dealt with, and it was pointed out that as the fine fibrous feeding roots were purely annual, as distinct from the more woody and permanent roots, the tree not only did not suffer by the removal of the former when the season's work was done and repotting effected, but that this was really essential in the interests of the following season's growth and crop. Repotting in practically the same sized pots and in entirely fresh top-soil loam, rammed very hard by successive ramming, as filling up proceeded, was recommended, and valuable hints were given as to the subsequent feeding by mulching composts. As, however, the paper and other points discussed will see the light of print in the Royal Horticultural Society's Journal, we must refer our readers to that for fuller details. We may, however, add that the discussion of the question of quite cold treatment, i.e., in houses entirely devoid of piping or other heating arrangements, led to the generally adopted view of the wisdom of a little provision in this respect, since though in many places it might be safe to dispense with any further protection than that afforded by glazing, both frost and fog in others involved risks at the critical flowering period which it was wise to avoid by a little heat, though only just sufficient to exclude frosts, any forcing methods being altogether outside the area of discussion. Pruning, too, was naturally entered into, and the success of Mr. Rivers' methods was evidenced by some capital photographs of trees, which evoked much admiration, both by the symmetrical form and abundance of bloom which, in most cases, they exhibited. A very hearty vote of thanks was accorded to Mr. Rivers for his very interesting and practical paper, and the meeting then dissolved with the customary feeling that the Horticultural Club had once more established its claim to be considered a useful as well as a pleasant centre of horticultural interests.

#### OBITUARY.

#### MR. DAVID SAUNDERS, OF FREAR'S WALK NURSERY, CORK.

A WORTHY man, a sincere friend, a great lover of his calling, has just gone to his mother earth, from whose sources while with us he gave by his labour and enjoyment of his work the rich products of many Irish gardens—flowers, fruits, and shrubs. He leaves a great blank behind, being as he was the mainstay at all exhibitions from the metropolis south to Cork. He is greatly lamented by his fellow-citizens, and the gardener out of place never had so good or sincere a friend. A widow and a numerous family have to mourn their great loss, yet few of us but can be done without, and the business will be conducted by his eldest son and his worthy manager.

W. B. H.

#### MR. COCKETT.

WE are very sorry to hear of the death of Mr. Cockett, who was for many years one of the trustees of the Horticultural Club, and a member of the committee.

#### ANSWERS TO CORRESPONDENTS.

**Names of fruits.**—Fennan.—1, Striped Beaufin; 2, Rosemary Russet.—Grower.—The Apple is Dr. Harvey. Allington Pippin is in season from October to December; on heavy soils it will keep longer.

**Names of plants.**—G. B. H.—1, Sedum kamtschatcum; 2, Sedum sarmentosum. This is not strictly hardy.

—Foreman—Salvia Horminum.

**Salvia virgata** (R. D.)—This is a true perennial, and generally considered hardy. It is a native of Armenia, and the species has long been known to cultivation. You do not mention the colour, but in referring to the plant you speak of "bright clumps," from which we take it you have been attracted by a highly coloured plant. S. virgata is white flowered. Could you send us a spray of the plant you have seen, then we may be able to name it, and it would save you disappointment in the future.

\* Several answers are left over until next week.

[NOVEMBER 1, 1902]

## WHOLESOME FRUIT.

WITH SPECIAL REFERENCE TO IRELAND.

CORRESPONDENT OF THE GARDEN

A has sent a letter, above the signature of "An Englishman in Ireland," to the *Irish Times* about the recent fruit show at Cork. It is a straightforward and sensible commentary upon the condition of fruit culture in the Sister Isle, but the letter applies with equal force to Britain in general. Fruit growing in England has not shown remarkable developments, though books, pamphlets, and articles have poured from the pens of writers, practical and otherwise—with some effect, it is true—but we have much to learn in spite of wholesale literature and such a splendid show as the Royal Horticultural Society provides each autumn at the Crystal Palace.

We give the following extracts from the letter, which is too lengthy to reproduce in full:—

"As an Apple show pure and simple it was equal to anything I have ever seen at the Crystal Palace, Shrewsbury, or elsewhere, but it was not equal to the great Apple and Pear conference held in the Royal Horticultural Society's gardens at Chiswick a few years ago. All fruits at Cork, except Apples, were only of average quality and limited in quantity. The one strong point in the show was the proof—if proof be needed—that the best Apples can be grown in Ireland as productively, as large, of as good quality, and probably finer in texture and colour than as grown anywhere else in the United Kingdom. Cowper, the poet, wrote long ago on horticulture:—

'If vain your toil, then blame the culture, not the soil.'

And this advice is particularly appropriate to this country at the present time. All that is wanted are more intelligent growers like those now so prosperous in the fertile district around Armagh, or those small fruit growers of one to three or four acres, who have for many years been quietly working away at Gormans-town. A good deal is said now and then about the fine colour of the American imported Apples, but probably no one ever saw Apples so clearly and brilliantly coloured as were a large proportion of those shown at Cork. A splendid collection from the warm limestone soil of Clare took everyone by surprise, as also did many of those from County Cork, and others from the celebrated old cider district, the Blackwater Valley of Waterford. The most brilliant Apple in the show was one named Scarlet Custard (? Costard), with a coat as deeply crimson-scarlet as a Tomato. It is believed to be an Irish seedling. As to good texture, juiciness, and flavour, the Irish-grown specimens of Cox's Orange Pippin and its

parent the old Ribston Pippin could scarcely be equalled anywhere else in the British Islands. Go where one may, all over the length and breadth of Ireland, you will find the best of fruit in private gardens, and as a fact some of the finest Apples and Pears ever exhibited at the Royal Horticultural Society's show in Dublin for many years past were grown at Rathmines, on the sloping banks of the Dodder, by the late Mr. J. F. Lombard, as an agreeable recreation in a busy life of business in town. The Cork show ought to encourage farmers and other cultivators of the land to have a greater and a firmer faith in it than they have hitherto shown, and as one good result it is to be hoped that new growers will commence fruit culture, slowly it may be, by at once planting half a dozen or more of the best kitchen Apples and a similar quantity of eating or dessert kinds. Before planting a few of the very best varieties of Apples in large quantities, it is wise to test the soil and situation by planting a few only; then, if they succeed, it will encourage the safe application of more labour and capital and land. It will take many years and many more fruit growers before we can hope to check American and other importations to our shores. The change of habit in the culture of new or different crops is a slow process everywhere. In France viticulture is hereditary—'in the blood,' so to speak—just as is the silkworm culture, or the growth and priming of Olives in Italy and elsewhere. The good work is going on, and on all sides one may see a renaissance taking place in fruit growing, and of horticulture, and woodcraft or forestry in Ireland. It is getting not only 'in the air,' but 'into the blood' of both gardeners and agriculturists. Not only must the best of fruits be grown in quantity, but the production of good fruit is only a part of a fruit grower's business; he must gather the crop and grade it carefully, pack it safely, neatly, or attractively, and, above all, honestly, and then he will have to study transit methods and charges, and all the many vagaries of the best markets. All this the Department is trying its best to instil into the minds of those interested, not only by inaugurating this show, but by the publication of useful literature as to grading and packing methods, &c., and if one may venture to prophecy we shall hope, by the publication as soon as may be of their official report on the Cork fruit show, a vast amount of further good will be effected. As to the great advantages of a more extensive use of good fresh fruit and of fruit produced by the people themselves, nothing need be said, seeing that good and wholesome fruit is like good wine, in so far that it needs only to be seen or tasted to be fully appreciated at its true value.

"The Agricultural and Technical Department is sometimes thought to be working like the mills of the gods, but slow and sure is not the worst of policies. It is only by object-lessons

and demonstrations like those instituted at the Cork exhibition that the masses can be reached and taught to use their land to the best advantage.

"Mankind generally are commonly said to possess only five senses, but there are others, and none higher than a fervent love of the native sod and a high faith in its innate fertility. In any case, self-interest may be appealed to very effectively, and by showing those connected with the land that its produce may be rendered more valuable, and that more profitable crops may often, even if not always, be introduced, is a noble and a national work, and one of the highest and best expressions of true patriotism."

## ROUND ABOUT A GARDEN.

THE SHRUBBERY IN NOVEMBER.

Few places can be so dank and sodden as shrubbery paths at this time of the year. The rain lies in adhesive layers among the fallen leaves which it brought patterning to the ground; and in the close, shrub-sheltered alleys November winds cannot exercise their scanty drying powers, while November fogs drip steadily into water from the shining wet branches overhead. The very ground seems to have entered the conspiracy of dank decay, for it thrusts all its mouldiness to the surface in fantastic shapes of fungi, clammy to the touch, and melting later into black unwholesome-looking slime. The fat-bodied garden spider spins its geometric moisture-spangled web just where you, ducking to avoid a dripping branch, may thrust your head into it. Apart from the irritation of clinging cobwebs on your nose, the large full-fed garden spider is not a good thing to carry off upon your person, in spite of the dainty decoration of its back. It can bite.

A MOIST OPPORTUNITY.

For these and other reasons one wanders less about a shrubbery in November than perhaps at any other time of the year, and if the paths have been neglected in late summer and early autumn they are now so cumbered with dripping grass and decaying weeds that you might as well wade in a brook. Yet more useful work can be done in the shrubbery now than at any other time. The gardener is in possession of the garden proper, for this is one of the periods of upheaval with spade and fork, and wholesale planting, which you may direct and supervise, but cannot perform. So, if you want to mess about with your own hands, you cannot do better than turn to the shrubbery. From late spring to autumn it has been almost out of hand, a scene of rampant luxuriance where, beyond aiding the plants that you like in their struggle for existence against undesirable neighbours, you could do little more than look on, admiring or deplored, as the case might be. But in autumn Nature's exuberant partisanship on

behalf of her own wildlings dies down, and she leaves you a clear field.

#### LIKE GOVERNING IRELAND.

Controlling the plant life of a shrubbery is like governing Ireland. You have to treat it with a judicious mixture of kindness and firmness; but you will usually find that it has taken advantage of your kindness to scramble all over the place, so that you are tempted to think you were not half firm enough. But do not attempt drastic measures. Coercion never pays; and if you sternly dig up a wild space in your shrubbery, because you disapprove of its behaviour this year, you will be amazed, if the soil is good, at next year's deluge of weeds—Nettles, Thistles, Twitch-grass, creeping Ranunculi, coarse Umbellifers, and everything unwelcome—that your spade seems to have let loose. Shrubbery gardening is work for trowel rather than spade, and it needs botanical judgment; but its triumphs are greater than those of flower-bed gardening, when you can wander down a winding path and discover at every turn dainty flowers flourishing among wildly natural surroundings.

#### THE COMMON OR GARDEN "SHRUBBERY."

Comparatively few people regard the shrubbery as part of the "garden" at all. Fewer still have time to undertake its care; and the trained gardener's traditions are all against such work. In dealing with defined spaces, such as flower-beds, which he can rake and dig, he knows what he is about; but shrubbery work, where you have to treat each plant as an individual in the struggle for existence, and aid it or repress it, according to its surroundings, is too "fussy" for him. Consequently there are few gardens where the shrubberies serve any other purpose than as a fence or a background to lawn or flower-beds. Usually the "shrubbery" is a dense mass of evergreens with a few trees in the middle; where the sparrows roost in crowds and cats prowl after them at night; where toads crawl among the snail-infested layers of dead leaves; but no human being, except a bird's-nesting boy, even thinks of penetrating its dank and gloomy interior.

#### THE "SHRUBBERY GARDEN."

Now, this is all wrong. If a dense shelter is needed it should at least be planted in a double row with a path between, and at once your impenetrable shrubbery becomes a sheltered pleasure, where one or more seats can be placed and where you can plant in the half-shade woodland flowers and Ferns that will flourish better there than in any other part of the garden. The shrubs themselves will grow far better through getting air and light on both sides, and the death of a large evergreen will not then create an unsightly gap in the shrubbery, but merely give you a temporary view of the shrubbery walk with its flowers and Ferns. And this is the season when, trowel in hand, you can discover hundreds of places where these may be judiciously planted. With such common things as Primroses, Forget-me-nots, Rocket, Foxglove, and Evening Primrose, common shade-loving bulbs, and British Ferns, you can effect a magical transformation for next year in the aspect of any neglected coppice or shrubbery; and from year to year, working in autumn and spring, you can add to its charms, until what used to be merely the fence or a neglected annex to your garden becomes the part where you always linger for pleasure and whither you take your friends with pride.

E. K. R.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

November 1.—Battersea and Derby Chrysanthemum Shows (each two days).

November 4.—National Chrysanthemum Society's Exhibition, Royal Aquarium (three days); Royal Horticultural Society's committees meet; Southampton and West of England Chrysanthemum Shows (each two days).

November 5.—Hanley, Margate, Northampton, Cardiff, Cambridge, Hereford, Sevenoaks, Truro, Southend-on-Sea, Halifax, and Ascot Chrysanthemum Shows (each two days).

November 6.—Chichester and West Sussex Horticultural Show; Cheltenham, Doncaster, Hornsey, Isle of Thanet, Manor Park, Tooting (each two days), Totnes, Ealing, and Evesham Chrysanthemum Shows.

November 7.—Leicester, Bolton, Barking and Ripple, Beaminster, Penzance, Winchester, Woolwich, Thornton Heath (each two days), Waterford, Colchester, and Newport Chrysanthemum Shows.

**Rose Mme. Jules Grolez.**—I am glad to see that the claims of this Rose to that general recognition which it undoubtedly deserves appear at last to be making some progress. At the same time, Mr. Goodwin is not doing the Rose justice when he describes it as scentless. I am afraid he must have been taking his fill at the ever-open fountain of La France before he reached his plants of Jules Grolez—in no other way can I account for his failing to detect its delicate fragrance. At any rate, be the reason what it may, my experience of the Rose is distinctly against Mr. Goodwin's verdict. And, although a Rose in a town or London garden may seem sweeter than it does in a country garden, from the greater contrast of its surroundings, yet it is only seeming after all, and I have little doubt Jules Grolez at Kidderminster is much the same as its cousin in town.—HERBERT E. MOLYNEUX.

**Vittadinia triloba.**—It must be twenty years since botanists tried to teach us that the plant common in gardens and nurseries, and then generally called Vittadinia triloba, the Australian Daisy, really belongs to a different genus, and is rightly named Erigeron mucronatus. The two plants are very easily distinguished, but the Vittadinia is hardly ever seen in gardens, though year after year we often see it stated in gardening papers and in nursery catalogues that the two names are synonyms. Vittadinia, as De Candolle and "Index Kewensis" spell the name, though the "Kew Hand List" has it Vittadenia, is a genus of several species, all natives of Australasia or of the Sandwich Islands. The plant described by De Candolle ("Prodromus," Vol. V., page 280) as Vittadinia triloba is now included in the name V. australis. It is a weak little bushy Daisy, not hardy in Edge Garden, having a very distinct form of leaf, each leaf ending in three equal lobes, joined at the base like three equilateral triangles placed side by side. The flowers are shabby with few rays, and continue white. Erigeron mucronatus (De Candolle "Prodromus," Vol. V., page 285) De Candolle wrongly makes the classical Greek name Erigeron (of the neuter gender) a native of Mexico. The leaves have two small lateral and one large central division, each of the three being tipped with a spike like the sting of a nettle, but harmless. The flowers, which are considerably larger than those of V. triloba, are white when they first open, and turn pink. The plant is perennial, and is quite hardy in Edge Garden, sowing itself on rockeries so as to be rather troublesome. Minutiae distinctions between Erigeron and Vittadinia will be found described in "Genera Plantarum" (Bentham and Hooker, published in 1875).—C. WOLLEY DOD, *Edge Hall, Malpas*.

**Mr. C. Harman Payne.**—The appointment, by the French Government, to the rank of Officier du Mérite Agricole of Mr. Harman Payne, gave the members of the Société Française d'Horticulture de Londres an opportunity of expressing their appreciation of the work of the corresponding foreign secretary of the National

Chrysanthemum Society, and the esteem in which he is held by them. Mr. Payne was on Saturday last entertained by members of the French society and other friends. Mr. G. Schneider presided. The object of the meeting was the presentation to the new officer of a miniature cross of the French Order, which, so far as we are aware, has been bestowed on half a dozen British subjects at most, and then only as Chevaliers or Knights. In calling the attention of the company to the splendid services which Mr. Payne has rendered to horticulture on both sides of the Channel, the chairman specially remarked that this is the first instance of a British subject having been raised to the rank of Officer. Mr. Payne having duly and graciously acknowledged the gift and thanked the company, Messrs. B. Wynne, T. Bevan, and Percy Waterer delivered appropriate speeches, reminding the company of the amount of work which the new Officer not only undertakes, but also carries out successfully every year, and assuring those members present that their guest would always, and in every way, do the greatest honour to the Order which has been conferred upon him by the Government of the French Republic.

**Peach Waterloo as a bush.**—For some years I have tried several of the early Peaches, such as Hale's Early, Early Alexander, and Amsden June, grown as bushes, and, so far, I must say the trees have not given a good return. There are several other varieties, such as Early York and Condor, but the best bush trees have certainly been the Waterloo. This has been our worst season; the severe weather in May played sad havoc with these fruits, and my advice to fruit growers of Peach trees grown as bushes is to give a sheltered position; grown thus there is no question that the fruit obtained is of excellent flavour and beautifully coloured. I think Waterloo, as compared with other varieties, worth a special note, both for its earliness, hardiness, and good flavour. I prefer Waterloo and Hale's Early to all others. These American varieties are the earliest to ripen, and if the trees are kept thin so as to mature the new wood they produce fine fruits.—G. W. S.

**The Pershore Egg Plum.**—In the Midland Counties and the West of England this Plum is grown in large quantities; indeed, in the Vale of Evesham and Pershore district I have seen enormous crops. The fruit was unsaleable; but at that time there were no fruit factories, so that doubtless this variety is now made good use of. My note is sent on account of the value of this Plum for cooking and preserving; indeed, I do not know of any variety that gives such a good return as an orchard tree. It does well as a dwarf standard, and few varieties are more robust. In shape the fruit somewhat resembles an egg. It has a clear yellow skin and pale yellow flesh, with a sweet vinous flavour. It may be called an early fruit, as it matures early in August. I am aware that soils greatly influence the crop as regards most fruit, but I have seen this variety in such poor soil and out of way places that I should think it would do well in any gardens where Plums are grown. Unfortunately, the fruits do not keep long, as the skin is very thin, but for home use, preserving, or other purposes they are most valuable.—G. W. S.

**A valuable late Plum.**—Few fruits of recent introduction have proved more valuable to growers than Rivers' Monarch, though this past season was a poor one for Plums. It is not quite a dessert variety, but, like Victoria, is useful for both purposes. It is also catalogued as a dessert fruit by some growers. It is a beautiful fruit, roundish oval, and one of the largest, the colour being dark purplish blue. It is a freestone kind, of good quality, but not rich. Its value is in its free cropping and its lateness, whilst the fruits do not crack in wet seasons. Grown on a wall they are very fine. We grow it otherwise, and it is most profitable. The tree is a strong grower, and it flowers later than some kinds; but I find it well to give it ample space and not prune it too much, merely thinning out where too thick. The trees fruit in quite a young state, as I noticed three year old trees fruiting grandly.—G. WYTHES.

**Browallia cerulea grandiflora.**—I think it is much to be regretted that names should be multiplied and new ones applied to well-known plants instead of those already generally accepted which everyone knows, as such a practice can only lead to confusion and the misleading of those who do not know plants. In a recent issue (on one of your unnumbered pages) a correspondent writes in high and well-deserved praise of Browallia cerulea grandiflora, which must, I think, be what is generally known as *B. speciosa major*.—W. E. GUMBLETON.

**Corn Exchange Chrysanthemum show.**—An excellent example of what can be done to assist the various charities is that set by the committee of the above Chrysanthemum show. The members of committee and officers of this society are well known on the London Corn Exchange, and their object in carrying out this exhibition is two-fold. In the first case, it is an endeavour to bring together in friendly rivalry the members of the corn trade in four classes, exclusively devoted to growers of the Chrysanthemum. There are also four classes open to amateur cultivators of the Chrysanthemum, who are non-members of the corn trade. The foregoing are to be staged on show-boards in the usual manner, and these, together with an open class for six blooms arranged in a vase, complete the list of competitive classes. A silver bowl and a silver cup are also provided, and these are given respectively for the grower of the best twelve blooms in the first four classes, and for the best twelve blooms in the amateur classes. The second object of this excellent institution is to sell the blooms by auction in aid of the funds of the Corn Exchange Benevolent Society, and with such a worthy object in view it is hoped the classes will be well contested. Such good work might with advantage to the charities be taken in hand by many of the more successful Chrysanthemum societies throughout the country, and it may not be too late even now to do something in this way. The honorary secretary of the show under notice is Mr. J. H. Mitchener, 1, Seething Lane, London, E.C., who will be pleased to send schedules to any grower who may be interested.—D. B. C.

**Vegetables at the Drill Hall.**—It was remarked of the specially fine collection of vegetables shown by Mr. Gibson (Mr. R. A. Hudson's gardener) at the Drill Hall recently from Marlow that it contained some dishes which would have improved the high quality of the collection had they been left at home. That criticism from the purely competitive aspect of vegetable exhibiting may have been quite correct, but it was not sound criticism in this case. Mr. Gibson's aim was to show a thoroughly representative collection of vegetables for the time of year, and in that respect he succeeded. I noticed one dish of the too little known or grown *Stachys tuberifera*, a capital sample of the tubers of this Chinese introduction. When properly cooked it is quite a delicious vegetable, but far from being an attractive exhibition product. There were other useful things shown that were not of the normal show order; but as a representative collection, both in quality and in variety, it was a splendid display, and not least of its merits was the arrangement, which thus created out of the products a work of art. Thoroughly well was the gold medal deserved.—A. D.

**Royal Horticultural Society.**—The next fruit and flower show of the above society will be held on Tuesday next, in the Drill Hall, Buckingham Gate, Westminster, S.W., 1–4 p.m. A lecture on "The Dietetic Values of our Common Vegetables" will be given at three o'clock by the Rev. Professor G. Henslow, M.A., V.M.H. At a general meeting of the above society, held on Tuesday, October 21, thirty new Fellows were elected, amongst them being Lady Owen Roberts, the Hon. Mrs. Wood, Colonel Henry Moore, and Colonel F. B. P. White, making a total of 1,005 elected since the beginning of the present year.

**Prospects of the Chrysanthemum shows.**—Mr. Norman Davis thinks that the backward season will tend to promote quality in the specimen blooms of Chrysanthemums which we are accustomed to see at the November show

at the Royal Aquarium of the National Chrysanthemum Society. If the experience of the last December show of the society can be taken as suggestive of what is likely to be seen next week, then there should be an exhibition of unparalleled extent and quality, especially of varieties of the incurved type. At the last of the three exhibitions to be held during the first week in December much will, of course, depend upon the weather. Fog and mist bring damp and mildew, and the flowers decay rapidly. Should conditions quickly change for the best, and dry, clear open weather follow, even if frosty, it would be much more favourable to the production of fine specimens, especially at the December show. There will certainly be a very good display at the Aquarium on Tuesday, Wednesday, and Thursday next.—R. D.

**Continental Chrysanthemum shows.**—This year will see a very marked progress in the exhibition of the Chrysanthemum on the continent of Europe. Almost everywhere shows are announced, but the principal ones will

of a reddish brown hue. The dark brown anthers are very conspicuous against the rest of the flower, although in showy weather the pollen is apt to mar its beauty.—T. W.

**Cimicifuga japonica.**—This plant seems to have been presented as a novelty to the floral committee of the Royal Horticultural Society at the Drill Hall on the 21st ult. But it is no novelty either to botany or to cultivation in England, as I have grown it at Edge for about twenty-five years, and given it away in more or less quantity nearly every year, as it is very easily increased by division. Its history may be instructive as showing how long a good hardy plant may continue in cultivation without becoming generally known. It was described at least as early as the year 1784 in Thunberg's "Flora Japonica," and again, early in last century, in De Candolle's "Prodromus," Vol. I., page 65, both times by the name of *Actaea japonica*. About the year 1843 Siebold put it into a new genus and called it *Pityrospurma acerinum*, but Bentham and Hooker, in "Genera Plantarum" (Vol. I., 1867) joined this genus with *Cimicifuga*, and the plant is accordingly enumerated in "Index Kewensis" and the "Kew Hand List" as *Cimicifuga japonica* (Sprengel). So much for its names; now for its cultivation in English gardens. About twenty-five years ago it was offered in the catalogue of Ware, then at Tottenham Nursery, as a Japanese novelty at a reasonable price under Siebold's name of *Pityrospurma acerinum*, and I at once bought it and found it easy to cultivate if not allowed to suffer from drought or hot sun. A few years later I saw it flourishing plentifully in Rhododendron Nurseries on the mill-stone grit soil near Matlock, Stephen Smith's at

Tansley, and James Smith's at Darley Dale—who offered it at four shillings a dozen—also under Siebold's name. After dry hot summers I have more than once replenished my neglected stock from that source. About ten years ago it was offered under its new name, *Cimicifuga japonica*, by a Colchester nurseryman at a higher price for one plant than I had paid for a dozen. I bought one and found it to be, as I expected, my old friend. It flowers with me usually from the middle of August to the end of September, but this season all autumn flowers are three weeks late. At the beginning of October this year I saw it flowering in large clumps in a very flourishing condition in a well-stocked herbaceous garden at Penmaenmawr. From the reports I read there seems to have been some confusion at the Drill Hall between this plant and *Cimicifuga simplex* (Wormsk), which is quite distinct. It is described by De Candolle ("Prodromus," Vol. I., page 64) as a variety of *Actaea Cimicifuga*, now *C. fetida*, abundant in Kamtschatka, but the variety has since been made into a species, and is grown and enumerated as such at Kew, where I saw and made a note of it in flower about five years ago, but I have never had it in my garden.—C. WOLLEY DOD, Edge Hall, Malpas.

**Kingston Chrysanthemum Society.**—The annual exhibition of this old society will be held on the 12th and 13th inst., in the warm and pleasant St. James's Hall. The area of this is materially less than that of the Drill Hall, but it is a far warmer and more comfortable hall. To meet the reduced space the schedule has been partially cut down. Owing to the dense fogs which prevailed last year the society's funds suffered severely, and therefore economy in expenditure as well as other reasons has governed the changes made. Mr. W. Hayward, the art florist of Kingston-on-Thames, is the active secretary, and we hope his efforts will meet with every success.—A. D.

**Cotoneaster rotundifolia.**—The Himalayan Cotoneasters are notoriously a difficult class to deal with, as some of the species run into one another by almost imperceptible gradations, so

undoubtedly be those at Paris on November 12–19, by the National Horticultural Society of France; Angers, November 7–9, by the French National Chrysanthemum Society; Havre, November 8–10; Nimes, November 1–3; Lille, November 13–17, organised by the North of France Chrysanthemum Society, which has recently been reorganised, and is now under new management; Contances, November 15–17; Lisieux, November 8–9; Bourges, November 6–11; Milan, November 8–12, organised by the Italian National Chrysanthemum Society; Brescia (Italy), November 5–9; Amsterdam, November 10–14, the annual show of the Netherlands Chrysanthemum Club, besides several others, the dates of which were not fixed at the time of writing.—C. H. P.

**Lilium Brownii.**—The accompanying illustration depicts one of the best garden Lilies, and one that has done well with me this year in a London garden. The flowers are large, trumpet shaped, and of an unusually thick, waxy texture; inside they are ivory-white, but heavily suffused with chocolate on the exterior of the three outer segments, so that the unopened buds are entirely

that the confusion which prevails in many places regarding their nomenclature is easily understood. An interesting group of the different Cotoneasters at Kew, most of which being at present fruiting are additionally attractive, is of considerable interest, and a good practical lesson may be learnt as to the successful grouping of the smaller growing kinds. The true *Cotoneaster rotundifolia* is, however, a delightful shrub, whose berries, borne in great profusion, are remarkable for their brilliancy. The usual habit of this species is to form a freely branched spreading shrub of 4 feet high or thereabouts, clothed with small, dark green, roundish leaves, most of which are retained throughout the winter unless the weather is particularly severe. The berries, which are about the size of Peas, are freely borne, and being when ripe of a bright scarlet hue a bush of this Cotoneaster is then conspicuous for a considerable distance. Of the smaller Cotoneasters it is decidedly the best with but one exception, and that is so dissimilar that a place may in most gardens be found for both. The exception just alluded to is *Cotoneaster horizontalis*, a sturdy bush whose branches are arranged in an almost horizontal manner. The minor branchlets are disposed in a regular manner on opposite sides of the stem, thus imparting to the branches a flattened frond-like appearance. The scarlet berries of this are very showy, while the leaves, which are deciduous but late in falling, become deeply tinged with yellow and red before they drop. When at its best it is entitled to a place among the brightest of shrubs remarkable for autumn leafage. Of the tree Cotoneasters the Himalayan *C. frigida* is now laden with its large clusters of scarlet berries. It is sometimes met with in gardens as *C. affinis*, but the true *C. affinis* is a different plant altogether.—H. P.

**Pampas Grass.**—For some years subsequent to its introduction in 1848 this was botanically known and still is generally met with in gardens as *Gynandrum argenteum*, but now I believe it is correctly called *Cortaderia argentea*. Differences of opinion may exist as to the necessity for changing the name after it has once become thoroughly fixed, but its great beauty at this season of the year affords no food for controversy, for it is in its way unapproachable. A good healthy tuft, with its long, arching, gracefully disposed leaves, is at all seasons decidedly ornamental, but in early autumn, when overtopped with its silvery plumes, there is then nothing to compare with it. Beside the ordinary form there is a variety with variegated leaves, and another in which the flower panicles are pinkish. This variety, known as Rendatleri, is not so beautiful as the type, but from its distinct appearance it is well worth a place in most gardens. In the South of England the Pampas Grass is hardy, but in more northern districts it cannot be thoroughly depended upon unless protected. The New Zealand *Arundo conspicua* (now *Cortaderia conspicua*), though less imposing, is harder than the Pampas Grass, and may therefore be planted in colder localities. Even this is, however, in many places benefited by a certain amount of protection. Both the above named prefer a good deep soil with ample supplies of water during the growing season, but stagnant moisture in winter is injurious.—T.

**White early-flowering Japanese Chrysanthemums.**—Except for the blooms of Mme. C. Desgrange, there was nothing striking in the white early-flowering Japanese sorts, until two or three seasons ago, when varieties of English origin were distributed by a few raisers and specialists. It has taken some time for these good sorts to gain notoriety, and although last season much was done to give them the prominence they deserve, it was not until the present season that their real merits were generally recognised. Mychett White, raised by the late Mr. Russell of Mychett, is a plant of poor constitution, and needs careful culture to get the plants in anything like good condition. The flowers, however, are charming and of the purest white; they also come fairly large without disbudding. The plant is free flowering and about 18 inches to 2 feet high, bloom-

ing the whole of September. From the same raiser I believe came Market White. This is infinitely superior in habit and constitution to the first-named, developing blooms of good quality and of the purest white also. In this instance, however, the period of flowering is rather later than in the case of Mychett White, the latter part of September and early October seeing the plant at its best. There is a newer sort which promises to eclipse the two kinds already described, and this is Doris Peto, another English-raised seedling. This new variety appears to possess all that is wanted in an early-flowering white Chrysanthemum. Its form is quite equal to that seen in the blooms of Mychett White, and the plant has a constitution and habit equal if not superior to that of Market White. The plant is free-flowering and grows about 2½ feet high. On the occasion of the trial of early sorts in Mr. William Sydenham's garden at Tamworth this variety was remarkable for its good quality. Satisfaction is another good ivory white Japanese flower, tinted cream in the centre. This is a plant but little known, but it deserves extended culture. To call it free-flowering does not overstate its value, and its height is about 2 feet. September is the month when its flowers are at their best. A good companion to the last mentioned is a variety named Mrs. Squire. This plant, grown in a pot or in the open border, is a great success. Its pure white blooms are highly valued, habit dwarf and branching, height about 2 feet. Queen of the Earlies, sent out a few years ago with a flourish of trumpets, has scarcely come up to the expectations formed of it. The plants grow into rather tall bushy specimens, and the blooms do not develop in a mass as seen in most of the early sorts. When disbudded, however, a limited number of large handsome blooms may be obtained. Late September and October with me sees the variety at its best. This brief list may well conclude with a variety distributed under the name of Parisiana. In this instance the blooms are large, and develop on a long and stout footstalk. This is an unique instance in which the blooms are large and at the same time full. A dozen flowers set up in a large vase with appropriate foliage would make a pretty decoration. The plant is not very free-flowering, and its height is about 3 feet. During the latter part of September this variety is at its best; it is, I believe, a plant of continental origin.—D. B. CRANE, *Highgate, N.*

#### EDITOR'S TABLE.

##### NEW APPLE RIVAL.

Messrs. W. Clibran and Sons, the Oldfield Nurseries, Altringham, Cheshire, send us a fruit of their new Apple named Rival. This was given an award of merit by the Royal Horticultural Society on October 9, 1900; it originated from a cross between Cox's Orange Pippin and Peasgood's Nonsuch. Apple Rival is a large, handsome, and beautifully coloured fruit; the specimen sent to us was unusually richly coloured in a season when hardy fruit is notably colourless. It is considerably larger than Cox's Orange Pippin, and the rich flavour is very similar to that of the most delicious of Apples, while the flesh is very firm. We should say it is an Apple that would keep well. The tree is described as "a free grower, with upright habit, a good cropper, and well adapted to orchard culture." With such characteristics, and an appearance that strongly recommends it, the Apple Rival should soon become a favourite.

##### SEEDLING STREPTOCARPUS.

Messrs. James Veitch and Sons, Limited, Chelsea, send us a gathering of blooms of Streptocarpus in a great variety of good colours. A considerable improvement has been effected in the flowers of Streptocarpus during the past few years, and those sent by Messrs. Veitch are quite representative. There are white, rich purple, carmine, pink, blue, and other coloured flowers, most of which are marked with other shades. The plants from which these blooms were obtained have been grown from

seed sown in January last. They are now in full flower in Messrs. Veitch's Feltham nursery, and promise to continue bright over Christmas. There is little difficulty, we are told, in having Streptocarpuses in bloom continuously during nine months of the year.

#### KEW NOTES.

##### INTERESTING PLANTS IN FLOWER.

###### Temperate House.

*ACACIA FRAGRANS*, *Fatsia japonica*, *Pitcairnia ferruginea*, and *Java Rhododendrons*, of which the following varieties are most conspicuous: *Aphrodite*, *Duchess of Edinburgh*, *Maiden's Blush*, *Mrs. Heal*, *President*, *Princess Beatrice*, *Scarlet Crown*, *Souvenir de J. H. Mangles*, and *Triumphans*.

###### Palm House.

*Clavija macrophylla*, *Hemitelia macrophylla*, and *Zamia Skinneri* with several cones.

###### Succulent House.

*Aloe africana* and *Kalanchoe kewensis*.

###### Orchid Houses.

*Angraecum eichlerianum*, *Bulbophyllum recurvum*, *Catasetum fimbriatum*, *C. splendens*, *Cattleya bowringiana*, *C. labiata*, *Cymbidium gammieanum*, *C. longifolium*, *Cypripedium harrisanianum*, *C. fo*, *C. Maywardii*, *C. Schlimii*, *C. tonsum*, *C. virens*, *Dendrobium secundum*, *D. Phalaenopsis* and variety *statterianum*, *Epidendrum vesicatum*, *Laelia autumnalis* var. *atrac-rubens*, *Listrostachys Monteira*, *Masdevallia reichenbachiana*, *M. veitchiana*, *Odontoglossum grande*, *O. madrense*, *O. odoratum*, *Oncidium bracteatum*, *O. excavatum* var. *aurosomum*, *Platycilnis cobbiana*, *Pleurothallis pulchella*, *Polystachya odorata*, *P. tessellata*, *Scaphosepalum ochthodes*, *S. punctatum*, *Sobralia decora*, and *Vanda cerulea*.

###### T Range.

*Begonia*, various species, and the following tuberous winter-flowering varieties: *Ensign*, *Idealia*, *John Heal*, and *Mrs. Heal*; *Cajanus indicus*, *Haemanthus multiflorus*, *Hippeastrum aulicum*, *Justicia calycotricha*, *J. quadrifaria*, *Klugia notoniana*, *Lindenbergia grandiflora*, *Oxalis hirtella*, *Pentas carnea*, *Plumbago rosea*, and *Tetranema mexicana*.

###### Greenhouse.

Among other things the following are conspicuous: *Acacia platyptera*, *Calceolaria Burridgei*, *Erica caffra*, *E. mammosa* var. *pallida*, *E. melanthera*, *Eupatorium odoratum*, *Funkia lancifolia* var. *tardiflora*, *Peristrophe speciosa*, *Primula Forbesii*, *P. obconica*, and *P. sinensis*.

#### THE ROSE GARDEN.

##### ROSES FOR ARCHES.

**W**HEN well covered with flowers an arch of Roses is one of the most beautiful features of the garden. The selection of suitable varieties requires much care, as nothing is so unsightly as an arch partly covered, and this is far too frequently the case owing to faulty selection. Then, too, the future requirements of such gross-feeding Roses must be provided for. Deep tillage, well-decayed farmyard manure, free drainage, and stimulants during active growth are the main points to remember. Pruning should consist merely of thinning out old or dead wood and shortening back laterals. If the thinning out can be done in September so much the better for the plants. The supports should be preferably of wood, and to give stability an inner arch of iron piping is recommended. For the free-growing Roses named below an arch 8 feet high would be

about right, providing not only a free passage beneath, but also producing an imposing effect. The variety now is so bewildering that it is difficult to make a selection. Since the advent of Crimson Rambler, the multiflora race has been much sought after, and rightly so. They not only make immense growth, but the effect of the flowers for the time being and the persistent way in which they remain on the plants give them much decorative value. Next in importance for this purpose are the Ayrshire and Evergreen Roses. Many individuals desire Roses of better quality, and for arches varieties are often planted that are quite unsuitable. It is true we have a few admirable varieties such as Mme. Alfred Carrière that make as brave a show in autumn as they will in summer, and possibly their number will be increased in the near future, but in the meantime to prevent disappointment the summer blooming ones should predominate. Locality would naturally make a difference as to the selection. For instance, I saw recently in the gardens of Compton Place, Eastbourne, a splendid arch of Claire Jacquier that must have been a beautiful sight when in bloom, but should hesitate to recommend this somewhat tender Rose for cold districts. The following are all good, named in order of merit.

*Crimson Rambler*.—Too well known to need describing. In no better position could this Rose be planted. By proper management the arches may be clothed with flowers from base to summit. It makes all the difference to the size of the trusses whether they are produced from sound young shoots or from old and weak ones. At all times a ravenous feeder, this splendid variety well repays doses of soot water and drainings from cow sheds a week or two before flowering.

*Félicité Perpétue*.—One of the most beautiful clambering Roses grown. Its great profusion and the neat little rosettes so delicately white and so faintly flushed are features one would increase if that were possible. The plant makes a bushy growth that is necessary in an arch Rose, and its lovely foliage is borne well into the New Year. The great advantage of this Rose is that the flowers are produced simultaneously with Crimson Rambler, thereby acting as a good contrast. I would strongly advise that arches be planted on both sides with one variety only, although I know many adopt the plan of having a contrast on the same arch.

*Flora*.—This is another of the *R. semperflorens* race, and is a splendid grower. Its flowers are rather larger than those of any other variety of the tribe; the colour is flesh pink. Judging from its ruby red foliage it looks as though it were a hybrid of the Tea Roses.

*Gloire de Dijon*.—As popular as ever, and one of the sweetest of Roses. Just now it is grand, its buds being more beautiful than in summer. If care be taken in pruning, and one old growth is cut right down each year, there should be no difficulty about the bareness at the base of this Rose. If the growths are taken down and slightly bent this action will induce new shoots from the bends and a well-furnished arch will be obtained.

*Electra*.—Being very free flowering, this Rose seems likely to supplant Aglaia, though scarcely so rampant. No one can deny its beauty; the lovely little yellow buds peer out among the white expanded flowers.

*Dorothy Perkins*.—At present rather scarce, but doubtless next year it will be plentiful, for it will root from cuttings most freely. No Rose has "taken on" so much in its first year as this

American novelty, and though a hybrid of *R. wichuriana* the growth is distinctly Rambler-like. The colour is a lovely pink.

*Mme. Alfred Carrière*.—Flowers flesh white, large, and sweet scented. A valuable white Rose, blooming well, late, and growing most vigorously.

*Rêve d'Or*.—This fine old Rose is gaining in favour and is not so tender as is commonly supposed. An eminent gardener told the writer recently that he found this a most reliable yellow, and it was also most valuable for its foliage, which is abundantly produced.

*Euphrosyne* (the Pink Rambler).—As time is necessary for such Roses as this to establish themselves one is apt to disown this class of Rose on that account. Euphrosyne is, however, very beautiful; the fine pyramidal trusses of tender pink flowers and the wealth of golden stamens are special features in this Rose.

*Carmine Pillar*.—Gorgeous in colour, beautiful in its pale green foliage, this charming Rose should be planted wherever there is room. The flowers are certainly very fleeting, but they make amends for this by their prodigious numbers.

*Queen Alexandra*.—This Rose, although a recent novelty, has gained many admirers. The colour is just the shade of pink that appeals to the eye, and shows what may be accomplished by hybridising.

*Reine Marie Henriette*.—I did not see how I could well leave out of a selection of native varieties a Rose which is such an old friend as this. If it be allowed to grow as it likes and not pruned, a splendid bunch results, not only in summer, but in autumn also. I am not sure that this variety will not be superseded by its daughter Noella Nabonnand, but it is yet rather early to give a definite opinion.

#### PHILOMEL.

#### AUTUMN ROSES AT SLOUGH.

Of late years the Rose has come to rank almost as the queen of autumn flowers as well as of those of summer. By the introduction of new, and the improvement of existing varieties of Teas, Hybrid Teas and others, it has been made possible for the Rose garden to be almost as bright with flowers during the autumn as in the summer months. Of this we were convinced when recently spending a short time in the Slough and Langley Nurseries of Mr. C. Turner. There are fields of Roses

ROSE FELICITE PERPETUE OVER GARDEN ARCH.

in astonishing variety, and in late September and early October they were a beautiful sight. Even some of the Hybrid Perpetuals quite proved their claim to be regarded as autumnal flowerers. A good number were bearing a second display of really excellent blooms; for instance, Mrs. J. Laing, Camille Bernardin, a good pale crimson; Charles Lefebvre, bright crimson; Ulrich Brunner, Comtesse de Ludre, Merveille de Lyon, Mme. Victor Verdier, bright cherry red; Marie Baumann, La France, Mme. Gabriel Luizet, a beautiful pink flower of good shape; Maurice Bernardin, rich crimson; Jules Margottin, Gustave Piganeau, and others. But the value of the Rose as an autumn flower is almost entirely due to the qualities of the Teas, Hybrid Teas, Noisettes, Chinas, &c., that add so much to the beauty of the garden when most other flowers are fading. The extensive plots in Mr. Turner's nursery which are devoted to the culture of such types of Roses as those mentioned above, a few weeks ago were rendered most attractive by hundreds of lovely flowers in such imitable shades of colour as only those Roses can show, and one could in looking at them almost imagine it to be summer again.

But few made a braver show than the well-known Augustine Guinoiseau, which, represented by both standards and dwarfs, carried a profusion of its exquisitely tinted flowers, a good deal paler in colour than La France, from which variety it is a sport. The charming characteristic of this Rose, and one that makes

it easily recognisable even from a distance, is the variety of form, colour, and, above all, the arrangement of its petals. Their chief beauty lies in the way they are disposed. *Beauté Inconstante* is another that should be held in high esteem by lovers of autumn Roses; its large coppery red blossoms alone made quite a picture. *Belle Lyonnaise*, too, was freely blooming, its large pale yellow flowers showing to great advantage. Everyone knows *Catherine Mermet*, and with most it is a favourite, so that *Bridesmaid*, another lovely pink Rose which somewhat resembles it, should also become popular, especially as it is apparently a better autumnal bloomer. We noticed that rich yellow Tea Rose *Billiard et Barré*, whose flowers are so lovely in the bud: *Viscountess Folkestone*, wonderfully free; *The Bride*, not perhaps so vigorous a grower as some, but bearing a beautiful flower—a creamy white sport from *Catherine Mermet*: *Souvenir de S. A. Prince*, *S. d'un Ami*, *S. de la Malmaison*, and *S. de Catherine Guillot*, the flowers of the latter being a copper colour, tinged and shaded with carmine, and the centre yellow.

Princesse de Sagan, Grüss an Teplitz (a remarkably strong grower and very profuse bloomer), and Marquise de Salisbury were strikingly good amongst the dark-coloured Teas and Hybrid Teas, while the charming blooms of Mildred Grant, Mrs. Edward Mawley, Maman Cochet, and Killarney were also prominent. Marie van Houtte has been particularly good this autumn, flowering most freely a second time, and its blooms have been most exquisitely tinted. Ma Capucine is a Tea Rose that must not be omitted, for it was equal to almost any we saw in the Slough nurseries. Although the blooms are not large, they are a wonderful combination of bronzy yellow. Mme. Falcot, bright buff yellow; Mme. Chedane Guinoisseau, bright canary yellow; Mme. Cusin, rosy purple, the petals being marked at the base with pale yellow; and Mme. de Watteville, salmon, white, and pink, were others we thought worthy of special remark. It is impossible to describe the never-ending variety of form and colour that a field of Tea Roses in bloom presents to the onlooker; it is a picture that to be appreciated requires to be painted in colours, not in words, and when one realises that the time of year is early October, one's wonder and appreciation increase. The Phloxes, Gladioli, and Michaelmas Daisies must look to their laurels, or they will before long have to give place to the Rose as the most popular of autumn flowers.

## SELECTIONS OF ROSES.

We have received so many letters asking for selections of a few good Roses for present planting that we give the following. The lists will be continued till finished. We ask our readers also to refer to some lists recently published. Quite new Roses will be dealt with separately.

## TWENTY-FOUR BEST TEA ROSES.

This list consists mainly but not entirely of Tea Roses suitable for exhibition, but we only name such varieties as are easily grown and likely to give general satisfaction in the garden. Varieties of this group that are of climbing habit will appear in a separate selection.

Alliance Franco-Russe, yellow ; Anna Olivier, buff ; Boadicea, peach ; Bridesmaid, pink ; Hon. Edith Gifford, creamy white ; Innocente Pirola, white ; Mme. Antoine Mari, rose and white ; Mme. de Watteville, lemon and pink ; Mme. Hoste, lemon yellow ; Mme. Lambard, salmon ; Mme. Vermorel, coppery yellow ; Maman Cochet, flesh ; Marie van Houtte, cream ; Medea, lemon ; Mrs. Edward Mawley, carmine ; Niphos, white ; Rubens, creamy white ; Souvenir de S. A. Prince,

white; Souvenir de Catherine Guillot, orange; Souvenir de Wm. Robinson, fawn, pink, and yellow; Souvenir d'un Ami, pink; Sylph, white shaded violet; The Bride, lemon white; and White Mamam Cochet.

## TWELVE BEST CHINA OR MONTHLY ROSES.

Aurore, orange; Common Pink, pink; Cora, yellow and carmine; Cramoisie Supérieure, crimson; Docher, white; Fabvier, scarlet; Fellenberg, rosé; Irene Watts, delicate pink and white; Mme. Laurette Messimy, satin rose; Mme. E. Resal, rose and yellow; Mrs. Bosanquet, flesh; and Queen Mab, apricot.

## THIRTY-SIX BEST DECORATIVE ROSES FOR SUMMER AND AUTUMN.

This list consists of the best kinds for producing a mass of effective and continuous bloom. The difficulty is to select thirty-six out of so many available, but we have endeavoured to name kinds that have superseded certain old varieties, for instance, *Gruss an Teplitz* instead of *Fellenberg*. Arranged alphabetically they are as follows:—

Armosa, rose-pink; Augustine Guinoiscean, white tinted rose; Beryl, orange; Canoens, rose; Caroline Testout, fresh pink; Corallina, rosy crimson; Cramoisie Supérieure, blood red; Enchantress, cream; Eugenie Lamesch, yellow; General Schablikine, red; Gloire des Polyanthas, rose; G. Nabonnand, pale flesh; Grüss an Teplitz, scarlet; Hon. Edith Gifford, white; Kaiserin Augusta Victoria, white; Killarney, flesh pink; Lady Battersea, cherry red; La France, pink; Laurette Messimy, rose and yellow; Liberty, crimson; Mme. Abel Chatenay, salmon; Mme. Antoine Mari, white and rose; Mme. Charles, apricot; Mme. Chedane Guinoiscean, yellow; Mme. Pernet Ducher, creamy white; Marie d'Orleans, deep rose; Marie van Houtte, cream; Marquise de Salisbury, scarlet; Perle d'Or, orange; Princesse de Sagan, blood red; Queen Mab, apricot; Souvenir de Catherine Guillot, orange red; Souvenir de Malmaison, flesh; Sulphurea, pale yellow; Viscountess Folkestone, creamy pink; and White Lady, creamy white.

## TWELVE STRONG-GROWING BEDDING ROSES.

Roses are sometimes desired to grow tall and yet not too straggling. In course of time many of the recognised bedding kinds can be obtained a good height by sparse pruning. A few varieties may be selected which produce the desired height more quickly; they are mostly semi-climbers. A dozen good kinds are:—

Wm. Allen Richardson, Longworth Rambler, Alister Stella Gray, Grüss an Teplitz, Gustave Regis, Belle Lyonnaise, Germaine Trochon, Waltham Climber No. 1, Sombrelle, Billiard et Barré, Cheshunt Hybrid, and Bardou Job.

(To be continued.)

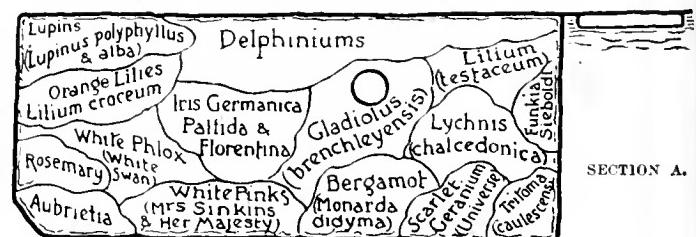

## THE FLOWER GARDEN

## WINTER SCHEMES FOR SUMMER COLOURING.

**L**AST week I ventured to draw attention to the great importance of endeavouring, when planting a border, to secure a harmonious effect of colour. The method which I have found most useful (after the dimensions of the border have been decided) is to set it out, as in the accompanying illustration, by means of a plan—a coloured one for choice. This enables me during the summer months to correct defects which are often difficult to bear in mind until the planting days come round once more. Perfection cannot be attained in a single season; climate

and soil, with their effect on certain plants in certain positions, must be studied, and personally I would far rather see the humblest flower *thriving* in my border than endeavour to acclimatise those, however beautiful or rare in themselves, which do not present a healthy appearance, and are evidently unsuited to the prevailing conditions; herein lies the explanation of what may possibly seem to be a very common-place list of hardy flowers. At first my ambition knew no bounds! Turning a deaf ear to the gardener's warnings, I planned innumerable effects with impossible plants; however, it is precisely in this way that experience is gained. The damp mists rising from the moat which shrouds Broughton during many autumn and winter days do more damage to the garden, if possible, than the late spring frost, although 7 and 8, during the early days of May, is not an infrequent occurrence. Water no doubt attracts frost, and what true garden-lover has not experienced a thrill of intense sadness to find, on a bright sunny morning, those tender green shoots, which only the evening before held such promise for the summer days, all shrivelled and black? Hence the omission from my plan of numerous plants which might be grown with perfect success elsewhere. It will be necessary, before working out a colour scheme, to determine during which months the greatest brilliancy of effect is required. The border here illustrated is planted for the months of May, June, July, and the first half of August.

As regards the arrangement of colours in their relation to one another, I always consider scarlet as the "high light" in my picture, and it is certainly the most difficult to fix in its proper position, for neither crimson, rose colour, mauve, nor even

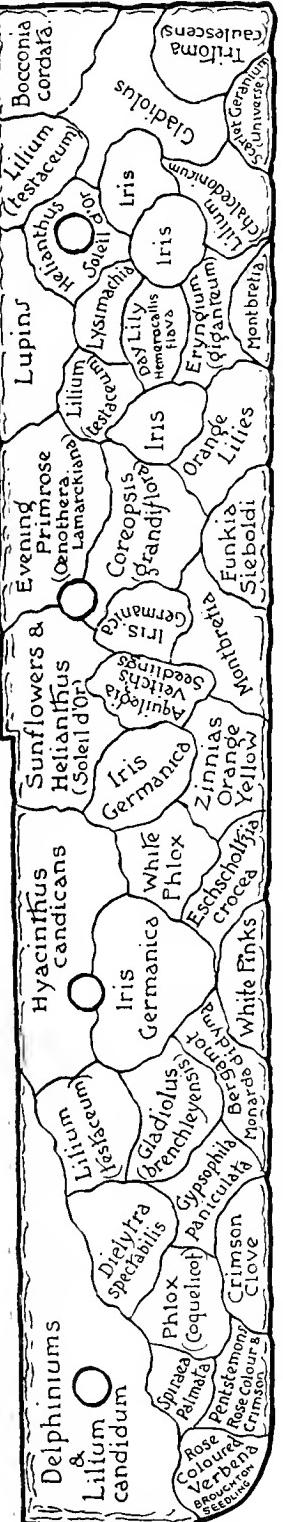

(Section C.)

*(Section B.)*  
**PLAN OF A MIXED BORDER AT BROUGHTON CASTLE.** (*Shown in detail in following plans.*)

137

(Section A.)

blue, to my mind, can be placed near it, and yet who would deny a place in the border to the beautiful scarlet Lychnis, Lilium chalcedonicum, or Sutton's Cardinal Poppy? It is, therefore, advisable to pass from these vivid shades, first through orange and yellow to blue, crimson, rose colour, and

white, separating them where necessary with cool tones, such as are to be found in the silvery foliage of Eryngium giganteum, Funkia Sieboldi, and cordifolia, or the feathery Gypsophila paniculata. Yucca gloriosa and Y. recurva, where they will thrive, are of immense value with their glossy blue-green spikes. At Broughton, alas! they are one of our failures.

A habit I employ, perhaps open to criticism, is the use of annuals in the front of the borders, but a personal love of colour must be the excuse, and there is no doubt that the effect which can be obtained by this means is dazzling in its brilliancy, especially during the early summer months.

We sow patches in the kitchen garden of all those which are likely to be of use, and then plant them out in the spring, when they fill the places of

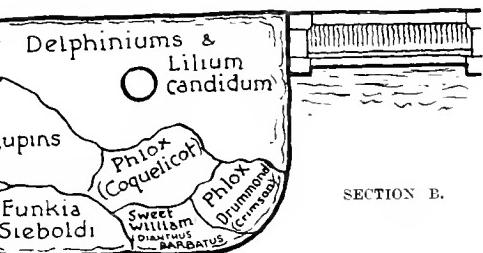

the early bulbs, thus allowing any alteration in the colour scheme which may appear needful. It is also allowable, I think, where circumstances do not permit the enjoyment of certain flowers in their own due season, to bring them on in gentle heat before planting them out in the border. This we do with such plants as Gladioli and Montbretias, both of which are dear to my heart; they replace the Oriental or bracteatum Poppies and tall May-flowering Tulips, and help to console one when the day—all too short, alas!—of the Delphiniums and Lilium candidum is past and over. Talking of Lilies reminds me that we find it useful to keep a certain number of these in reserve in the kitchen garden, in case those in the borders should be attacked by disease; they can then be sunk in pots where required. Last year that mysterious decay which appears halfway up the almost full-grown stem, causing it to fall over and wither away, made every testaceum its victim, and it was all the more annoying when one had accustomed one's self to believe that the beautiful Nankeen Lily, of all others, seemed to thrive. The following appear to be suited by our soil (a rich loam): L. Brownii, L. testaceum, chalcedonicum, croceum, and davuricum. L. candidum, most beautiful of all, seems with us to do best in a very dry season, so that possibly it is the damp at Broughton which militates against its real success. Iris germanica (marked on the plan) includes, besides Iris pallida, many named varieties, one of my great favourites being Queen of May, its rose-lilac petals veined with yellow. Iris florentina, or "flower-de-luce" of the early writers, should not be forgotten, the flowers lasting a considerable time for an Iris—these delicate shades mingling with the white and purple Lupines and the late rose-coloured Tulips, tufts of Aubrieta clustering round the stems, form one of the prettiest pictures imaginable during the latter end of May and early June days.

Involuntarily I lay down my pen as my thoughts stray away from the past (through the gloom of a November fog) to the future, wondering what the coming winter holds in store for the garden that we love. May it deal tenderly with the plants sleeping under the frost-bound earth, until the flowers awake once more to gladden the hearts of those who have wearied for them through the dreary winter days!

BLANCHE GORDON-LENNOX.

#### CACTUS DAHLIAS FOR THE GARDEN.

PERMIT me to join with Mr. Fitzherbert in thanking you for your editorial article on "Fashions in Flowers," and particularly for your remarks regarding the Cactus Dahlia. For the many who grow the Dahlia as a decorative plant for the garden it is absolutely misleading to visit the shows with the expectation of selecting varieties for garden effect, especially when the selection is made among the modern Cactus Dahlias with narrow petals, which look well, perhaps, on the show board, but are too often worthless as garden flowers. Nor is it always easy to select suitable varieties even on a visit to

a nursery where they are largely grown for sale and so cultivated to ensure having flowers for exhibition. I have frequently visited nurseries for the purpose of observing the best varieties for the garden, but have found it difficult to make a selection with any certainty, as the plants are generally treated in such a way as would spoil their usefulness as decorative border plants. They are often deprived of many of their branches and thinned out so severely as to check luxuriant growth that it is impossible to tell with any degree of satisfaction which are the most suitable varieties for the garden. It ought always to be borne in mind that for one who grows the Cactus Dahlia for show there are hundreds who cultivate it for effect and for giving plenty of cut flowers for the house. The older decorative varieties have frequently more merit with this object in view than the new Cactus ones. Such a plant as the old decorative variety Glare of the Garden occurs to one as a model flower for such a purpose as many grow the Dahlia for. I have been familiar with it for years, and have observed with some pleasure that it is again being propagated in some quantity for large gardens where the Cactus Dahlia in its most fashionable form is of little value. One does not wish to discourage the culture of the best Cactus Dahlias, but it is a mistake that they should oust from the garden and prevent the further improvement of the decorative Dahlia.

S. ARNOTT.

[Lady Ardilaun is one of the best Dahlias for effect we have seen this year.—ED.]

#### NOTES ON HARDY PLANTS

##### ECHINACEA PURPUREA.

**I**F a really good high-coloured selection of this plant could be got it would soon become popular. I have occasionally noticed with surprise the numbers of poorly-coloured forms that pass muster for Echinacea purpurea, so poor that one could scarcely consider them worthy of garden space. Many plants show that shade of colour I must describe as bleached purple, rendered still paler by the rich crimson-purple of the cone, and fading to a purplish grey under the influence of a few days of warm sunshine. Others, infinitely more desirable plants, show something of the rich purple colouring displayed on the coloured plate given with THE GARDEN some years ago. The plant is of good habit and every other characteristic of a garden plant save the colour of its ray florets. Judging from the range of shading displayed in an exhibit of cut flowers I saw recently a re-selection would result in something commendable. One would welcome a good rich purple form.

##### LATHYRUS ROTUNDIFOLIUS (WILLD.).

THIS is a free-flowering Oriental species of pleasing habit, and well adapted for the border. It reaches a maximum height of 6 feet, but is more frequently 4 feet or 5 feet. The growths are neat and thickly set with flower spikes every few inches of their length. Each spike has a dozen flowers, which are slightly smaller than those of *L. latifolius*, and of a deep rose in colour, with a shade of copper showing on the face of the standards, the reverse being tinted bronze. Like most *Lathyrus*, the plant requires a year or two to establish itself

before its true worth can be seen. The habit, a loose one, can be rendered compact, yet free, by inserting a few Pea sticks about the plants over which they can ramble at will. The slender sprays of roundish Pea-like foliage and pretty flowers closely packed on the stem may be cut freely without injury to the plant, as each lead removed will induce numerous breaks from the old stems below, thus considerably extending its season of flowering. The plant does not appear so well adapted for clothing walls, trellis, &c., as *L. latifolius*, for the growths do not attain the same height and vigour; but for the border, with a few sticks for support, it looks quite at home. It may be raised from seeds, but the seedlings are slow in growth.

#### PHYSOSTEGIA (DRACOCEPHALUM) VIRGINIANA ALBA.

THIS, the rare white form of the well-known North American *Physostegia*, gives promise of becoming quite as strong and as free as the type, though one rarely sees an old-established specimen. It grows 2 feet high, and bears branched four-ranked spikes of white tubular flowers (which are somewhat inflated above the middle) averaging an inch in length and closely arranged together. A rich free soil of good depth, such as one would choose for *Phloxes* of the decussata section, suits the plants well, but in heavy retentive soils the roots decay in winter, and the plants are a long time re-establishing themselves in spring. On the other hand, it is one of the first to suffer from drought in a poor light soil, the whole plant drooping badly after a few weeks' warm sunshine, hence the need of a deep root run of good tilth, and perhaps a mulch of old manure should the weather be very dry.

G. B. MALLETT.

#### ASTER AMELLUS PERRY'S FAVOURITE.

THOSE who can look back for a few years cannot but be struck by the improvements effected in the Starwort, and it is gratifying to those who have long recognised the value of this flower in the garden to see the measure of popularity it has attained. That there is still room for improvement must be admitted, and one especially looks forward to the acquisition of new forms of the fine *Aster Amellus*, though there are now a few really good varieties in cultivation. For some years I have waited for a rose or pink variety, and I thus made a point of securing that called Perry's Favourite this spring. It is now in bloom, and one is glad to recognise in it one of great merit in point of colour. It is a good rose or pink, and makes a charming variety, either in the garden or for cutting. Of course Asters of the *Amellus* section do not produce the pyramidal plants of some of the others, but the size and beauty of the individual blooms, as well as the neat habit of the plants, make them among the most desirable of all Michaelmas Daisies. Such a variety as Perry's Favourite is sure to add to the popularity of this class.

S. ARNOTT.

#### ARENARIA BALEARICA.

THIS little Sandwort is one of the prettiest and most interesting of all our little rock plants. I have often known people to look through the rock garden and take but little interest in the plants generally, but when they have suddenly discovered this little cushion-like plant covered with its countless little starry flowers on slender stalks a little more than an inch long growing perhaps upon a rough piece of sandstone rock, or, as I have often seen it, luxuriating on the grass path in front of the rockwork, an interest has been awakened and a love for the plant established never to be forgotten. In looking round the beautiful grounds of Lord Battersea, at Overstrand, near Cromer, a short time since we came across several very fine dense masses of this little plant. Here, close to the sea and only protected by shrubs and tall herbaceous plants, this plant is quite at home, the culture of which reflects great credit on the gardener, Mr. Clements. Now is the best time to

plant. If done at once it will soon establish itself and flower freely the following spring and summer. To establish it I have found it best to plant firmly in any good light soil near the rocks or stones we wish to cover; it will soon approach and begin to clothe them. It is readily increased by division, and when once established will seed freely. It will grow on most soils, but I have always found it do best on sand or gravel. On cold soil it will sometimes perish in winter. Its true home is on the rockwork: it will well repay any trouble that may be taken to establish it.

T. B. FIELD.

### THE ROCK GARDEN.

#### THE ROCK GARDEN IN OCTOBER.

**F**LOWERS are becoming scarcer every week, especially among the smaller rock plants. Among the taller plants, such as would scarcely adorn the rocks themselves, but would be either forming the background or be interspersed between the rocks, there is still quite a galaxy of brilliant colours, the brightest of them being, perhaps, the scarlet Lobelias. But even among rock plants proper many bright colours still prevail, and since there is nothing like a practical example, I think I cannot do better than give a list of plants which I have actually seen in flower during this October in a rock garden which is scarcely two years old, namely, the Rectory Garden at Camborne, Cornwall, which, though very much exposed, shows, nevertheless, still a wealth of colour in spite of the adverse season. Here is the list of plants in bloom as noted down on the spot:—

<i>Asterisens maritimus.</i>	<i>Cyclamen hederifolium.</i>
<i>Potentilla alchemilloides.</i>	<i>Anemone sylvestris.</i>
<i>Sidalea candida.</i>	<i>Hypericum moserianum variegatum.</i>
<i>Fuchsia procumbens.</i>	<i>Sempervivum Laggeri.</i>
<i>Campanula isophylla alba.</i>	<i>Sentellaria rupestris.</i>
<i>Phygelius capensis.</i>	<i>Oxalis valdiviana.</i>
<i>Veronica spicata.</i>	<i>” floribunda.</i>
<i>Chrysogonum virginianum.</i>	<i>Arenaria grandiflora.</i>
<i>Dianthus Paucifl.</i>	<i>Calandrinia umbellata.</i>
<i>Maurandisia barclayana.</i>	<i>Polygonum Brunonis.</i>
<i>Brickellia grandiflora.</i>	<i>” vacemifolium.</i>
<i>Aster canescens.</i>	<i>Claytonia sibirica alba.</i>
<i>Spigelia marilandica.</i>	<i>Polygonum chamaebuxum purpureum.</i>
<i>Campanula pumila alba.</i>	<i>Asclepias tuberosa.</i>
<i>Erigeron aurantiacus.</i>	<i>Tunica Saxifraga.</i>
<i>Coronilla Emerus.</i>	<i>Nierembergia filicaulis.</i>
<i>Reseda glauca.</i>	<i>Achillea tomentosa.</i>
<i>Enothera missouriensis.</i>	<i>Antirrhinum glutinosum.</i>
<i>Statice profusa.</i>	<i>Moly.</i>
<i>Sedum Telephium.</i>	<i>” alba.</i>
<i>Galega officinalis alba.</i>	<i>Ethionema cordifolium.</i>
<i>Liatris scariosa.</i>	<i>Vittadenia triloba.</i>
<i>Campanula van Houttei.</i>	<i>Linaria palida.</i>
<i>Enothera taraxacifolia.</i>	<i>Silene Armeria.</i>
<i>Callirhoe involucrata.</i>	
<i>Androsace oculata.</i>	
<i>Convolvulus Chœurum.</i>	

Even this list of over fifty plants is not quite complete. There are several among those enumerated which are blooming the second time or which were mentioned as being in bloom last month. But that does not alter the fact that they are blooming now in October. Many of the plants named above have not been previously mentioned, and among these I may describe the following:—

*Nierembergia filicaulis* is a half-hardy perennial, hardy in Cornwall but not hardy in the northern counties. It is very unlike the better known *Nierembergia rivularis*, which, as the name would imply, loves a moist spot and grows only 2 inches or so in height. *N. filicaulis* reminds one more of a *Linum* growing about 15 inches to 18 inches high, and bearing blush white flowers  $1\frac{1}{2}$  inches across tinged with lilac. It is a very striking plant and flowers abundantly in October. Its leaves are very small and are borne on slender stems.

*Oxalis floribunda* is quite hardy in the Cornish garden referred to, but must be considered a greenhouse plant in the North. Its flowers are bright pink and abundantly produced.

*Oxalis rubidiviana* is of the same degree of hardiness, and resembles the former generally,

though growing somewhat more robustly, but the colour of the flowers is a bright golden yellow. It does well in a comparatively dry position.

*Scutellaria rupestris* is not so well known as *S. alpina*, which was mentioned last month. It has purple and white flowers, while those of *S. rupestris* are blue. The plant grows about 8 inches or 9 inches high. It is a pretty rock plant of the bolder type.

*Hypericum moserianum variegatum* is a pretty rock shrub preferring a half shady position, where its variegated leaves and bright yellow flowers show to great advantage.

*Cordyline Ueorum* is very erratic in its time of flowering; I have known it in bloom at Christmas. At Camborne it is in flower now, and a very attractive plant it is with its silvery leaves and large pale pink flowers.

*Enothera taraxacifolia* is a fine plant of the bolder type; its strong prostrate shoots covered with large white flowers at this time of the year make it desirable for a position where its strong growth does not impede the smaller alpines. *Enothera missouriensis* is also a strong-growing, trailing plant, but it has deep yellow flowers.

*Campion van Houttei* and its paler form *C. v. H. pallida* are still very bright—the one with deep blue and the other with pale blue flowers. It seldom grows more than 12 inches or 15 inches in height, and its bell-shaped, somewhat elongated flowers are several inches long.

*Statice profusa* is well named; it bloomed in March, and has been blooming more or less profusely ever since. Unfortunately, it is not hardy except in the warmest and most sheltered spots, and must generally be considered a greenhouse plant.

*Reseda glauca* has cream-coloured flowers resembling the hardy British plant *Reseda luteola*, but the foliage is of a beautiful glaucous green. It grows about 9 inches to 12 inches in height.

*Shortia galacifolia* is not now in bloom, but its handsome leaves have turned a scarlet-crimson, and they are almost more ornamental than the pale pink flowers which appeared in early spring.

*Seseli cuspitatum* is a peculiar rock plant with glaucous laciniate leaves, and just now bearing numerous umbels of white flowers.

*Brickellia grandiflora* has peculiar tassel-shaped flowers of a pale yellow or straw colour. It grows about 18 inches high.

*Phygelius capensis* is a taller and more robust plant, about 2 feet in height, and produces its deep red tubular flowers at this time of the year in abundance.

*Fuchsia procumbens*, with its purplish blue flowers and neat, creeping habit, is hardy in most of the southern and western counties. It is a neat trailer, now blooming, and bearing later on seeds of the size, shape, and colour of a small Plum. A half-shady place seems to suit it best.

*Antirrhinum glutinosum*, the large-flowering white Snapdragon, prefers a sunny spot. Its somewhat prostrate habit and woolly foliage add to its attractiveness.

#### CLIMBERS

Of climbing plants now blooming the most beautiful are the various kinds of *Clematis*, of which an enormous number are still in bloom. In the west of Cornwall, however, where a milder climate prevails, many choice climbers are now in full bloom, which might well be used for covering bold natural rocks or artificial rock walls of considerable height, but in a very sheltered and warm situation only. The following are now blooming near Penzance in the gardens at Trewidden:—

*Lophospermum scandens*, a half-hardy perennial, which makes an excellent climber and bears *Gloxinia*-shaped large flowers of a pleasing pink colour.

*Manettia bicolor* is really a greenhouse climber, but does well out of doors in several parts of Devon and Cornwall. The leaves are small, but the flowers are showy, being scarlet and yellow in colour and tubular in shape.

*Pentstemon cordifolius* is quite hardy, not only in the south, but also in the Midlands; it is very unlike any other *Pentstemon*, being of a shrubby

nature and growing 8 feet or more in height. For covering large rocks it is excellent, and its scarlet flowers, about 1 inch to 1½ inches in length, are still very bright.

*Maurandia barclayana* is another half-hardy perennial now flowering in the West. Its flowers are violet in colour and bell-shaped.

*Hidalgoa Wercklei* (the climbing Dahlia), with its bright scarlet flowers, I also noticed in bloom at Trewidden, but whether it will stand the winter is doubtful.

#### MEDIUM AND TALL HERBACEOUS PLANTS FOR BACKGROUND.

Asters, and Anemones of the *Anemone japonica*

might be said of the handsome *Senecio pulcher*, which is still bright and showy.

*Elmside, Exeter.*

F. W. MEYER.

#### SUMMER SHOWERS.

##### THEIR EFFECT ON GARDEN FLOWERS.

THOUGH the wise man knows there is nothing new under the sun, yet however true the abstract proposition, we often note something or another as quite novel in our own personal experience. For myself, I cannot remember in twenty-five years of gardening a season so remarkable as this summer and autumn have been for exceptional growth in the vegetable world.

I attribute it to the continuous attentions of the clerk of the weather from mid-July to end of August, when out of forty-six days we had rain on twenty-five, and when the aggregate fall here was 414 inches, while on August 16 and 18 we had 83 inches and 81 inches respectively.

This growth was shown in our kitchen gardens by the extraordinary crops of Peas, French and Runner Beans, Cabbages, Broccoli, and Cauliflowers, the latter (fine ones) selling in our local shops at a penny each. In June we picked many Strawberries that ran eighteen or twenty to the pound, and one berry which weighed 1½ oz. Last month we gathered a basket of Apples, the "poor man's friend" kind, of which a large number averaged 10 oz. to 12 oz. each; six of them scaled 4 lb. 9 oz. in all, and a single specimen weighed 14 oz.

But it is the growth in my herbaceous borders which strikes me as still more abnormal, and in illustration of which I send for your acceptance some memoranda of heights attained and a couple of photographs. These latter represent *Verbascum olympicum* and the double *Rudbeckia* (*R. laciniata flore-pleno*); they were taken in my garden here on June 10 and September 8 respectively. The Mullein was a grand specimen, over 6 feet high, and one compact sheet of yellow bloom; the Rudbeckia was 8 feet 1 inch, and a very beautiful object.

I have a perennial Lupin 6 feet 10 inches in diameter, which had about 150 bloom spikes upon it. This Lupin is an interesting specimen, which sprang naturally in my garden some four years ago, being, as I believe, an accidental hybrid between the pretty dwarf *L. nootkatensis* and the common blue *L. perennis*.

I subjoin a list of measurements just taken, and accurate, of the heights of various plants in my borders. It may interest some of your readers to compare it with the average heights of the same species of plants:—

		Height. Feet. Inches.
<i>Philadelphus grandiflorus</i>	..	14 7
<i>Helianthus tuberosus</i> (Artichoke)	..	13 —
<i>H. argyrantha</i>	..	9 4
<i>H. Miss Mellish</i>	..	7 7
<i>H. decapetalus</i> (lemon coloured)	..	7 —
<i>Harpalium rigidum</i> <i>grandiflorum</i>	..	8 3
<i>Physostegia imbricata</i>	..	8 —
<i>Solidago altissima</i>	..	7 4
<i>Dahlia</i> Empress of India	..	8 2
<i>Boltonia latisquamata</i>	..	8 2
<i>Aster Novae-Angliae</i>	..	6 8
<i>Ditto</i> (pink form)	..	6 4
<i>Aster</i> (species)	..	6 6
<i>Silphium perfoliatum</i>	..	7 7

I may remark that these plants have not been forced in any way by heavy manuring or special culture of any sort—the soil is a sandy loam.

I am sorry to add that the lack of strong sunshine in August has, I fear, prevented due ripening of the luxuriant growth in many of our shrubs, which will probably suffer in proportion should a severe winter supervene.

HORACE WADDINGTON.  
Roseneath, Godalming.

#### BRITISH HOMES AND GARDENS.

##### MENTMORE.

OME of the loveliest gardens in England are to be found under the shadow of the Chiltern Hills. The beauty of the scenery seems to have acted as an incentive to the owners of the many beautiful seats in Buckinghamshire, and the most has been made of good soil and good position, backed up by ample means and a genuine love of gardening. One of the most delightful of all these gardens is that of Mentmore, which is now owned by Lord Rosebery, and was formerly the property of his father-in-law, the late Baron Myers de Rothschild. Of this fine estate of something like 10,000 acres, the main portion is, of course, given over to ordinary farming, but near the residence Lord Rosebery has about 100 acres under fruit, and a walk through the orchard with the capable head gardener, Mr. Smith, is a pleasure which it is worth while going a long way to enjoy. A large tract of land is devoted to Plums grown for market, Victoria, Coe's Golden Drop, and Prunes being among the most profitable sorts, though others are grown to keep up a succession of fruit. Apples are an important feature, each variety planted in a row to itself, and it is worth noting how few are the varieties in comparison with the total number of trees grown. Mr. Smith is strongly of opinion that it is a mistake to grow too many kinds, and for the most part confines himself to well known Apples. Blenheim is prominent, and so are Wellington, Cox's Orange Pippin, Lane's Prince Albert, Ecklinville, and Fearn's. Always a good Apple is the verdict about Ecklinville, and it is a pleasure to see the fine clean growths, without the slightest trace of insects or disease. Bramley's, on the other hand, grows too rank and does not fruit well, and the Ribston is almost invariably found to canker at a certain stage of its growth. It seems a pity this fine Apple cannot be freed from this trouble, but as the complaint comes from all localities after trials on all manner of soils, one is reluctantly forced to the conclusion that it is due to inherent weakness or to some peculiarity that it is vain to strive against. Mr. Smith is much impressed by Newton Wonder, which he considers likely to be a general favourite when its merits become known. His method of dealing with the trees is to cut out a limb every year instead of removing the top branches, as he holds that it is easier in this way to preserve the tree's balance and to allow the admission of light and air into the centre. Certainly, judged by results, the plan answers admirably, for an ill-shaped tree is here quite the exception.

Of Pears grown in the open the most striking in appearance is Fertility, its handsome shape being almost as noticeable as the enormous number of fruit-buds in evidence at the time of our visit in the spring. A high word of praise was given to Catillac, absolutely the best stewing Pear in existence. The Autumn Bergamotte is a favourite; the curious fact may be mentioned that some specimens of this Pear in the most perfect condition were found at Christmas time in the long grass beneath the trees. Such a method of storing will not commend itself to growers, but it may afford a useful hint, nevertheless. Most of the Apples, if not all, are on the English Paradise,

RUDBECKIA LACINIATA FL.-PL. IN THE GARDEN OF MR. HORACE WADDINGTON, GODALMING.

type are now represented at their best, but the varieties in either genus are so numerous that a mere enumeration of them would fill more space than would be available for this essay.

Of Salviæ the variety Blue Beard is very showy just now, its purple bracts being uncommonly bright, forming a good companion by way of contrast to the taller *Actinomeris virginica*, a hardy perennial not often seen except in the western counties. The plant grows 3 feet to 4 feet high, and its bright yellow composite flowers are exceptionally neat. Belladonna Lilies, too, are now in full bloom, and their large pink flowers are most attractive. The same

and some cordons of Gipsy King, growing around the borders a couple of feet or so from the ground, are on the same stock, and yield an excellent crop of good fruit. The shoots were covered with buds, giving every promise of a fruitful yield. Seventy-two tons of mixed fruit were sent off in one year, and this is not by any means a record, though the returns from the largest yield were not so satisfactory, so true is it that something more than a large crop is needed to make a profitable season. The Pears are grown on the Quince. On the walls Peaches are grown and ripen well, so that a good succession is maintained, the trees in one of the houses already bearing small fruits, while in another there was an ample display of bloom. The same need of keeping up successional supplies is evidenced by the care bestowed upon the Vines—which were in all stages of growth—and Strawberries, some of which were beginning to colour, while out of doors there were very large beds devoted to this crop. A question which has often been discussed is the length of time a Strawberry bed should endure. Many good gardeners have come down from three years to two, and Mr. Smith

other climbers are hanging to provide graceful beauty in their season; whole beds among the conifers are filled with different kinds of Spiraeas; Roses are grown in great profusion, while one of the latest additions has been a preparation for a pergola or covered way. This covers a large space of ground. Many hundreds of climbing plants have already begun to make their way along the wires, and a photograph of this a few years hence would be worth reproducing. Coniferous trees are very numerous, and there are several magnificent specimens of Cupressus lawsoniana, one nearly 70 feet high. This is one of the districts where Wellingtonia gigantea bids fair to justify its name. Some specimens raised from seed sown by Mr. Smith on March 20, 1878, and planted out in 1880, are now nearly 50 feet high. These seeds, by the way, were shot down from a tree in California by the late Sir Richard Quain, the well-known surgeon.

If it were permissible to deduce the character of the owner from an inspection of the garden, one would have to describe Lord Rosebery pretty much as the public knows him. It shows the

gardens, and that the loss caused by their removal will not be compensated for by the extra light and air given to things growing around them.

A few words in conclusion. The gardener's residence is a beautiful old manor house covered with climbers, and a bothy erected for the accommodation of twelve gardeners is a building of handsome design. There are altogether thirty-eight gardeners and labourers employed, and the grounds are kept in admirable condition. The mansion itself is somewhat modern, and the arrangement of the grounds in the immediate vicinity was the work of Sir Joseph Paxton.

#### AUTUMN FLOWERS.

EARLY September sees our gardens at their fullest and brightest. The large bold plants have completed their growth, and the latest of the half-hardy annuals are in their prime; Dahlias, Nasturtiums, and African Marigolds provide brilliant colours; Clematis flammula flings its cloudy mantle over bush and tree, and fills the air with wandering sweetness.

The illustration is a picture of a corner of a garden in Hampshire; it is instructive in that it shows the pictorial effect of simple plants well used, and encouraging in that there is nothing in it that might not be done in any garden—even quite a humble one.

#### MOUNTAIN PRIMULAS.

##### PRIMULAS FOR OPEN GROUND OR GARDEN USE.

(Continued from page 217.)

*P. FLAGELLICAULIS* (Kern.) is a hybrid of *P. acaulis* and *P. officinalis*.

*P. inflata* (Reich.), syn. *P. panonica* (Kern.).—A variety of *P. officinalis*. Calyx rounded, inflated; leaves abruptly contracted to the petiole, undersides greyish.

*P. intermedia* (Facch.). Southern Tyrol, syn. *variabilis* (Gouy.), *brevistyla* (DC.). Figured in Reichenbach's "Icones XVII.", t. 62.—A hybrid of *acaulis* and *officinalis*.

*P. intricata* (Gren. et Godr.).—See *P. elatior* var. *intricata*.

*P. macrocalyx* (Bunge), syn. *P. uraleensis* (Fisch.).—A variety of *P. officinalis* with spreading, widely campanulate calyx. A garden form of *P. acaulis* with an enlarged and monstrous foliaceous calyx is often sold under this name.

*P. media* (Pet.) syn. *P. unicolor* (Nolte), *decipiens* (Loud.), *leudrensis* (Porta).—A hybrid of *P. officinalis* and *elatior*.

*P. officinalis* (Jacq.).—Distributed throughout Central and Northern Europe. Figured in Reich. "Icon. XVII.", t. 49; syn. *P. odorata* (Gil.), *ambigua* (Salisb.). A well-known plant; with *P. elatior* the origin of the coloured Primroses of gardens. It was brought into English gardens towards the end of the sixteenth century, and has been considerably altered and improved under the name of Cowslip. The leaves are wide and abruptly contracted to the petiole, covered with a light greyish pubescence, strongly ribbed and reticulated; flowers small, drooping; in *elatior* they are upright, bright yellow with five orange spots at the base. Very sweet scented. There is a curious variety (*P. officinalis duplex*) with a double corolla, one, strung as it were, over

AUTUMN FLOWERS (CLEMATIS FLAMMULA, FRENCH MARIGOLDS, ETC.) AT FAIRFIELDS, HANTS.

states that he is veering round to the opinion that one year is even better than two. Certainly the finest fruits come from the youngest plants, and this year he is experimenting, on a somewhat large scale, to decide the question for himself whether it is not more desirable to break up the plantation every year. British Queen does very well at Mentmore, and a fair number of plants of this sort are grown.

The visitor is struck by the variety of the gardening at Mentmore. There are about forty houses in which specimen plants in endless variety and flowers from Primulas to Orchids may be found; there is one erection devoted entirely to Carnations, and there is a splendid Palm house. Out of doors there is hardly a phase of the art which does not find expression, and though formal gardening does not seem to be highly favoured, the Italian garden, near the house, is an admirable specimen of this difficult, and to most people not very attractive, style. A border on a terrace overlooking the kitchen garden is, by the owner's direct wish, kept filled with old-fashioned flowers, such as may be seen in cottage and farmhouse gardens. From some of the trees Clematis and

characteristics one would expect to find in the garden of the versatile individual who, while one of our most brilliant public speakers, has made a name in literature, is a prominent statesman, and yet can find time to devote himself to horse-racing and other sport. It is this broadness of character that has helped to give the ex-Premier the high place he occupies in the English-speaking world; it is the same characteristics that make his garden worth inspection. There is no "faddiness," no exclusive devotion to one class, but a liberal broad-minded adhesion to all that is worthy of a place in a good garden where space is ample, and there is no lack of labour, and yet there is a strain of conservatism too. There are some fine old Wych Elms whose shadows fall over the fruit trees, and whose roots fill the soil no doubt to their detriment, but they are not to be touched on any account. And we must confess that looking at their gnarled trunks—most curiously fashioned and their picturesque outlines we can sympathise with the feeling that prompts the order. His lordship evidently does not need to be reminded that there are none too many of these old and twisted Wych Elms growing in British

the other, though the lower one is really a calyx altered into a corolla.

*P. suaveolens* (Beet?).—A syn. of *P. Columnne*.

*P. Tommasinii* (Gren. et Godr.) ; syn. of *P. Columnne*.

*P. uralensis* (Fisch.) syn. of *P. macrocalyx*.

*P. variabilis* (Gouy.) ; syn. of *P. intermedia*.

*P. veris* (L.).—This is the old name given by

Linnæus to *P. acalis*, *P. elatior*, and *P.*

*officinalis*, and which by custom has been

given to garden Primroses in general, that is to

say, to the mixture of all the varieties.

*P. vulgaris* syn. of *P. acalis*.

I have purposely excluded from this treatise the Primulas that are not hardy and must have greenhouse treatment, such as *boveana*, *floribunda*, *imperialis*, *obconica*, *prolifera*, *sinensis*, and *verticillata*, as they do not come within its scope.

I desire to thank the readers of THE GARDEN who have followed me thus far in a study of the Primulas; it has been made in the hope of rendering some service to the many admirers of this beautiful genus who may have found themselves puzzled by the great mass of synonyms with which it is burdened, and who may also have been misled by the involuntary errors of those who send out species incorrectly named.

HENRY CORREVON.  
Geneva.

N.B.—I may add that I should be happy to communicate with anyone who wishes to write to me on the subject of Primulas, or, indeed, of any other plant, whether to add to my own information or to answer their enquiries. The address given above will suffice. H. C.

showing flower, if not actually in bloom. Afterwards they must be gradually kept drier till they go to rest. Each plant will generally produce several rhizomes, and any particular variety can be readily increased thereby. If the tops of the young shoots are taken when they are about 3 inches or 4 inches long and inserted as cuttings they will easily strike, but this is a method seldom adopted. If artificially fertilised they seed freely, and, if the crossing is carried out in a systematic manner, some very interesting forms may be obtained. The seeds, which are very minute, should be sown in heat in February, and if treated like the Gloxinia—to which, indeed, they are

and most interesting of the many lovely leguminous plants which are found wild in Australia, the peculiar shape of the scarlet flowers with the large and curious black blotch at the base of the upper petal compelling attention. The difficulty experienced in its cultivation is in getting it to grow freely during the first few months of its life, for, although the seeds germinate freely and the tiny plants may grow well for a few weeks, they are almost certain to become stunted. If this happens they rarely grow away again, but gradually dwindle away and die.

To overcome this difficulty in some places grafting has been resorted to, with the result that very fine well-flowered plants have been obtained with no more trouble than attends the cultivation of ordinary greenhouse plants. The stock used is the common Bladder Senna (*Colutea arborescens*), and the method of procedure is as follows:—Seeds of the Colutea are sown singly in thumb pots plunged in bottom heat about three weeks in advance of those of the Cianthus. By this means the stocks are a little firmer than the scions when grafting takes place. The operation should be performed when the seedling Cianthus are but a few days old, before if possible, but at any rate not much later than the development of the first true leaf. Needless to say at such a tender stage the operation is a very delicate one and needs performing with great care, both stock and scion being very soft and slender. With a very sharp knife, however, and care there need be little risk of spoiling the scion.

The methods of side and inverted saddle grafting may be used, in the latter case inserting the wedge made by the scion between the cotyledons of the stock. A single tie with some soft material will be found sufficient to keep the graft in place till a union has been effected, which may be looked for in from ten days to a fortnight providing a fairly brisk bottom heat and a very close atmosphere are given; a bell-glass placed over the plants is a very good plan to adopt. After the union is effected the plants should be gradually brought into the open house. From this stage they should never have a check. As the stock is a quick grower, frequent repotting will be found necessary, using rich fibrous loam with which a fair quantity of sand has been mixed.

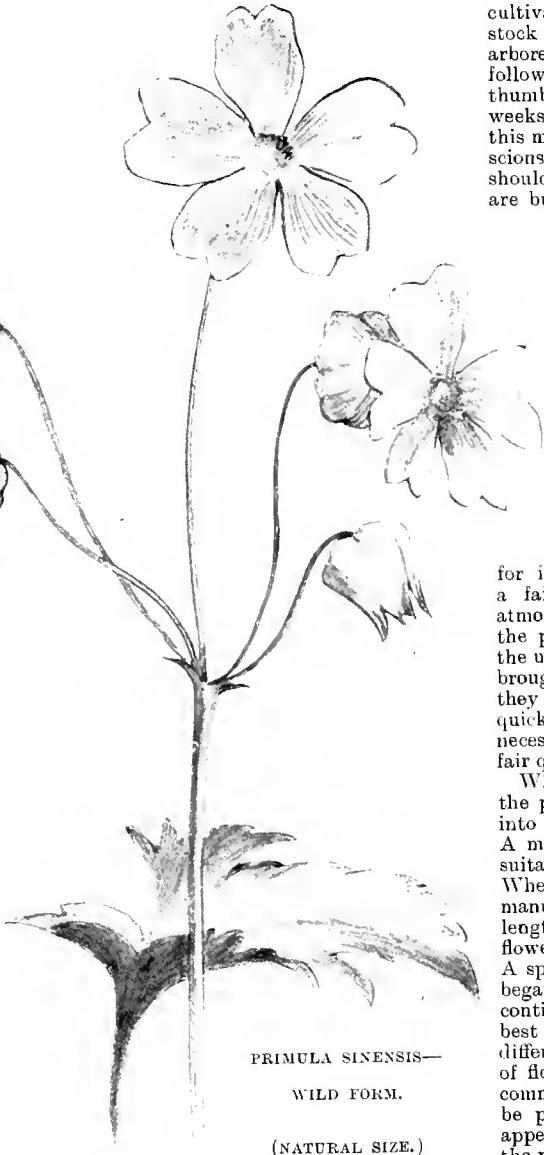

When 5-inch or 6-inch pots have been reached the plants should be transferred at the next shift into hanging baskets, and in these they will flower. A minimum temperature of from 45° to 50° is suitable and a light airy position is necessary. When the baskets are well filled with roots manure water may be given with advantage. The length of time the plants may be expected to flower depends to a great extent on their strength. A specimen grown in an 18-inch basket at Kew began to flower in February of last year and continued to do so well until October, being at its best from May until August, and at several different times it carried more than forty heads of flowers. Stopping of the shoots is not to be commended. When they get very long they may be pegged round the basket, or, if the plants appear to be growing away with one strong shoot, the point may be pinched out, and that will cause a number of growths to spring from the base, but by stopping shoots do not readily spring from buds on the stem, as is the case with most plants.

W. DALLMORE.

## THE INDOOR GARDEN.

### TYDÆAS.

W HATEVER they may be botanically—and on that point there seems to be some doubt—the plants known generally as Tydæas are particularly valuable for flowering during the autumn months. Their period of blooming is not limited to the season just named, for they may be grown to flower throughout the greater part of the year, but the bright-coloured flowers are perhaps more appreciated now than at any other time. They are nearly related to the Achimenes, and the rhizomes or cornis are a good deal similar, but more robust. Anyone desirous of commencing their culture can obtain them very cheaply when dormant in the winter or early spring. They should be potted at once, as they suffer if kept long out of the soil. A liberal amount of vegetable matter is required in the potting compost; a mixture of equal parts of loam and leaf-mould, with a good dash of sand, suits them well. When potted—say, early in March—they should be placed in a cool house and given just enough water to keep the soil slightly moist until the young shoots make their appearance. If a warm greenhouse temperature is maintained during the spring months, by May they will be sufficiently advanced to be shifted from 3-inch into 5-inch pots. In the summer a cold frame is a very suitable place for them, and towards the end of August they will need a little heat. At that time they will be

PRIMULA SINENSIS—

WILD FORM.

(NATURAL SIZE.)

nearly related—most of the young plants will flower in the autumn of the same year. These garden forms of Tydæa are usually classed by botanists in the genus Isoloma, one species of which, *I. hirsuta*, is sometimes planted out in mixed beds in Hyde Park, and bears its bright-coloured flowers towards the latter end of the summer.

T.

### THE CULTIVATION OF CLIANTHUS DAMPIERI.

MANY are the attempts made to cultivate this beautiful plant, yet it is seldom that well-flowered specimens are to be seen. Without doubt, when well grown it is one of the brightest coloured

### "LILIES FOR ENGLISH GARDENS."

I NOTICED Mr. Robert W. Wallace's remarks on my criticisms of the above charming addition to our garden literature, which now floods the British market, truly Adam and his followers in the gardening art have at no past period been placed on so high a pedestal. Napoleon called the British "a nation of shopkeepers." I wonder what great man will call us a nation of

"blue aprons." It is but four years and a half since I left the shores of Old England, and during that time from this distance it appears to me that people at home have gone mad over gardens. Dr. Masters used to speak of us Lily growers as Lily maniacs, or some such name. Then came the daft Daffodil men, but now the frivolous British public have put on the serious aspect of their character, and to feed them with suitable food a publisher is out of the running unless he has works on gardening—a good wholesome sign if it will induce people to go to bed early and rise with the sun. A friend of mine here spends a lot of money on his garden. He gets up at 5 a.m., and he and his coloured men start with a cup of coffee and then commence carrying water for the Roses, Dahlias, &c., but plants in tins have a bad time of it generally, as the water is poured on whether needed or not. I told him that his investments pay in ensuring robust health and happy days. He replied they do, and it was this three hours work before business that made him spend money so freely on his garden. But this you will say is not answering Mr. Wallace.

L. Henryi is no doubt a very distinct Lily, but all the same I consider the L. tigrinum section covers it. Mr. Max Leichtlin considers it only a form of L. tigrinum, and he is not a bad judge. When I had formed my opinion I submitted it to my good friend, as I am cautious in advancing an idea which may differ from generally received opinions, and my motive was to draw attention to the subject by having the plants L. Henryi and L. tigrinum grown side by side and note their characteristics. Mr. Leichtlin and I may be mistaken, and I think if the verdict is given against us we shall humbly bow to it. Mr. Wallace may have been the first to offer L. Henryi for sale, but I think I could prove it had passed through two and most likely three hands before he received it. I never like to give away trade secrets, and perhaps Mr. Wallace will await my return to settle this point. I do not know where I got my information of the plant being called a yellow L. speciosum, but certainly not from Mr. Wallace, as I saw very little home gardening literature till I arrived in Cape Town in August, 1901.

The Japanese-grown bulbs of L. longiflorum attain a much larger size than they do in Bermuda, hence there is more food for the Japanese L. longiflorum to live upon, consequently a greater number of flowers to a plant. Should the cultivation of L. longiflorum for shipping be followed up as I have suggested in the Cape Peninsula you will get bulbs that are capable of giving up to twenty flowers. In Japan I did not hear of any variety that had more than fifteen flowers. The description given of L. Harrisii quite agrees with a form of L. longiflorum growing here in the municipal gardens, and which is the first to flower, but not the one that gives the most flowers. I saw the same plant in Japan, broad, dark green foliage, and suggested it should be grown separately, but the Japanese, like the great financiers who support one metal as of standard value, do so on the same principle, as it is easier to work one than two. So the Japanese decided to get rid of all but the one with the long, narrow leaves, being the most floriferous, and I suggest the name L. longiflorum multiflorum.

I have much pleasure in giving Mr. Wallace the authority for the names L. speciosum roseum album and L. speciosum punctatum album. It was no other than the conceited writer of this letter. The names Krætzeri and album novum appeared to me meaningless, and as the true L. speciosum roseum has a green stem and L. Krætzeri has a green stem, the conclusion was simple. L. speciosum punctatum has primrose anthers and L. speciosum album novum has primrose anthers, so the conclusion as to the relationship was again simple. The colour of a L. speciosum bulb largely depends on exposure. L. Batemanniae and L. venustum I invite anyone to plant side by side, the bulbs European grown and the same size, and see if they can distinguish the one from the other, that is always supposing that the L. Batemanniae has been some years in Europe. I do not wish to cast any

reflection on the judgment of my old friend Mr. Wallace's father, but, like the writer, he was fallible, and I think he erred in judgment. Mrs. Bateman on one occasion asked me what this Lily was Dr. Wallace had named after her, and I gave my opinion that it was simply L. venustum, and as L. venustum and L. Batemanniae are not known in Japan as different plants, it is fairly conclusive, I think, that the plant is under two names, the best selling one being L. Batemanniae. Amateur and trader have been benefited by the naming of Dr. Wallace.

Mr. Wallace regrets I did not contribute to the Lily conference of 1901. I knew nothing of the conference till it was over. The Royal Horticultural Society does not rise to its opportunities, or it would give years in advance a list of its proposed conferences, and this it could easily do, as I have years ago suggested to members of the Royal Horticultural Society's Council, by printing on its schedule the conferences, say, five years in advance and the anticipated conferences, so that exhibitors would have a chance of making preparations, but the Royal Horticultural Society has hitherto sprung upon its members in January the conference for the year—a very short-sighted policy, and in some cases I have noticed a marked disadvantage to the Royal Horticultural Society. It was not till I reached South Africa that I had the chance of reading gardening papers. In 1900 I saw a *Gardener's Chronicle* in a newsman's office at Sydney, and, noticing an extraordinary letter from Mr. Sutton dealing with the Royal Horticultural Society's trials at Chiswick and his experimental grounds, I borrowed the paper to answer the same on my first voyage amongst the South Sea Islands, and posted my answer at Fiji, but it went into that Hades which is the terror of budding journalists—the Editor's waste-paper basket.

Cape Town.

PETER BARR, V.M.H.

## GARDENING OF THE WEEK.

### INDOOR GARDEN.

#### ROSES IN POTS.

**W**HEN a special house can be set apart for the cultivation of these plants they may be pruned and removed indoors now. Very little fire-heat should be given at first, but it may be gradually increased as the plants start into growth. Syringing may be practised daily until the new shoots are about an inch long, but after this it should cease. Careful ventilation is most important in the early forcing of Roses. Cold draughts or the exposure of plants to sudden changes of temperature are sure to bring mildew, which is a troublesome enemy if not kept in check. Growers who have to force their Roses among other plants should keep them out of doors for another month. Hybrid Perpetuals may be plunged in ashes out of doors until required for forcing. In severe weather they should be protected with some dry Bracken. The Teas are safer placed in a cool pit or frame.

#### CAMPANULA PYRAMIDALIS.

In order to prevent the ill effects of excessive moisture these plants in pots should be plunged in ashes or cocoanut fibre in a cold frame during winter, and afforded plenty of ventilation to prevent damping or undue excitement of the plants. Personally, I am favourable to their having the full benefit of the winter's frost, for they start into growth more readily and flower earlier than those placed in frames.

#### SUCCULENTS

will need but little water during winter, and most of them delight in a rather dry atmosphere. Almost all of them enjoy full light. The nearer they are kept to the glass the better they will flourish. The numerous species and varieties of Cactus and Phyllocactus are most interesting and attractive flowering plants, and no class of plants is more easily grown.

#### MIGNONETTE.

Damp in cold frames will be injurious to the well-being of these plants. Let them be brought indoors from the frames and placed near the glass in a light and well ventilated position. The stems should be provided with neat stakes to which they should be secured as they grow in height. The earlier batches coming into flower will greatly benefit by having frequent applications of weak liquid manure water given them. Later batches should be thinned to three or five in a pot as occasion requires. As the stems of Lilliums die down the pots may be plunged and covered in a bed of ashes or cocoanut fibre out of doors, where they will remain plump and sound until required for starting. One of the most important conditions for the successful cultivation of plants during winter is light. Cleanliness of the houses, and especially of the glass, so that sunlight may not be obstructed, are also important essentials. An effort should be made to wash the interior of all glass houses.

Wexham Park, Slough.

JOHN FLEMING.

### THE KITCHEN GARDEN.

#### ASPARAGUS.

THE growths should now be cut down, using a pair of garden hedge shears for the purpose. The surface should be hoed, all weeds and rubbish raked off and burned, and whenever the weather will allow give a thorough coating of good half-decayed farmyard manure, which should be covered with soil taken from the alleys, leaving them neat and tidy for the winter. Few vegetables are more highly appreciated than Asparagus when forced, and few things are more easily produced. No time should be lost in making a commencement, selecting good strong crowns for the purpose. It will be necessary to provide a mild hot-bed, consisting of three parts fresh leaves and the rest long stable litter; this may either be done in low houses, pits, or frames. The roots should not be kept out of the ground longer than is necessary or they will suffer in consequence, therefore they should not be lifted until everything is in readiness to receive them. Cover the crowns immediately to the depth of 4 inches or 5 inches, using a light porous compost. Thoroughly water in and syringe morning and afternoon. When made up in the open on hot-beds it will be necessary to keep the frames well lined with fermenting material as the heat declines in the beds, and the frames should be covered at night.

#### POTATOES

which were lifted and placed away under temporary cover should now be carefully looked over, removing every tuber which has the slightest trace of disease, and I fear in many places all the late crops have suffered considerably. The sound tubers may then be stored away, making them quite secure against frost.

#### HORSE-RADISH.

Part of the bed should be taken up yearly and a twelve months' supply stored away where it can be easily obtained: this is by far the best method. Very often it is dug up as required, which means that many of the young crowns are spoilt and the bed always presents an untidy appearance. Any time after this date the work may be taken in hand. We always make a practice of doing half the bed yearly. First open a deep trench and the sticks may then easily be lifted. Work in plenty of farmyard manure at the bottom and on the second spit, and plant medium-sized sets, burying them 1 foot below the surface. If the land is kept well manured there is no reason why good Horse-radish may not be grown on the same ground for years. The part which is not lifted will be much benefited by receiving a good dressing of old hot-bed manure. Every endeavour should be made to produce a free, quick growth.

#### CABBAGE.

Look carefully over the beds and make good all vacancies with the strongest plants from the seed bed; carefully plant and make them as firm as possible. Should the weather remain open it will be well to make yet one more planting in a warm,

sheltered part of the garden. Should a severe winter be in store for us these will probably come through much better than the earlier ones, which have made an unusually free growth this autumn.

E. BECKETT.

### THE FRUIT GARDEN.

#### POT VINES.

The house for these should be now cleansed and prepared for starting those that are intended for early use. A shallow bed of fermenting material, consisting chiefly of leaves, with a little stable litter added, should be prepared in such a way as will admit of the canes being trained near the glass, but be careful that a violent heat is not created, for it is not safe to subject the roots to a temperature exceeding 60°. Top-dress the pots with turf loam mixed with a suitable fertiliser and wood ashes, and firmly plunge them, with

damp from the house by ventilating freely on clear days, and as far as possible excluding it in wet or foggy weather by keeping the ventilators closed. Examine the bunches daily, removing decayed berries, and use first the bunches of bad keeping varieties that commence to decay, which are invariably those whose berries have not been properly thinned. Should the sun be powerful enough to discolour Muscats, shade the bunches with sheets of paper, which will also assist to prevent shrivelling.

#### EARLY FIGS IN POTS.

If the instructions respecting the repotting, top-dressing, and the placing out of doors of early pot trees have been attended to they will now be in a fit condition to be prepared for forcing. Having had their shoots properly disbudded or stopped during the growing season no pruning will be required, but should this have been neglected

cut away any weak or other growths that encumber the trees and then cleanse them. Brown scale is frequently troublesome, but it can be easily removed by a mild solution of soft soap and warm water, applied with a brush. This must be carefully done, so that the embryo fruits are not injured. For starting the trees into growth a mild hot-bed, similar to that recommended above for pot Vines, should be made, into which the pots should be plunged, the trees being near to the glass, and afforded sufficient space to develop their foliage properly. Commence forcing gently by keeping an artificial night temperature of 50°, that for the day being 55°, with 10° more from sunheat. It is surprising what fine crops may be grown upon even small trees of this description provided they are well fed while their fruits are developing.

T. COOMBER.

fortunate in securing seeds of the best form, as figured in the work above cited on plate 52. As an autumn-flowering, cool greenhouse shrub this *Hoheria* deserves notice, and it might eventually prove hardy in Cornwall or Devon, or in the south and west of Ireland, the sheltered warm glens of County Wicklow, and other mild localities. The plant may be raised from New Zealand seed, or it strikes from cuttings of the young growth readily in spring. It is a distinct free-blooming shrub of which more is likely to be heard when it becomes plentiful in gardens.—F. W. BURBIDGE.

## THE KITCHEN GARDEN.

### THE POTATO CROP IN 1902.

**U**NDOUBTEDLY the year's Potato yield is a question which concerns many, the consumer as well as the grower being quite justified in reviewing the prospect with some misgiving. Records already given of Potato crops prove that this scarcity is not confined to any particular district, but is more or less universal. Comparison between two succeeding seasons shows them as opposed one to the other as is possible for them to be. Last year Potatoes were almost a drug on the market at digging time, and in the late spring they proved to many a hopeless reserve. This autumn the majority of growers lament the smallness of their stock, and disease makes an uncertainty of those already harvested. Those varieties which have done well this summer will, no doubt, create a demand for seed of their particular kind in the coming planting time. In this neighbourhood a variety that is in particular favour with almost every class of cultivator is Up-to-date. Those who planted largely of this Potato are rewarded with a yield envious to those who had pinned their faith on some others, and the quality few, if any, complain of. In a year like that of 1901 there was in Up-to-Date a tendency to become coarse and hollow, but no such complaint is heard this year. A variety that has always done well with us is Clarke's Maincrop, good in quality, uniform in size, very even in crop, and hardy. This time it fell much below its usual standard, the yield being a better sample for seed than kitchen use, and the balance therefore between this and Up-to-Date goes heavily in favour of the last-named. Both are very good disease resisters. Syon House and British Queen, two others that have been grown, have both passed beyond hope for future planting in the field. In the garden the first-named is a good variety, and is one well spoken of by many growers, and that, too, for field work by some. I am entirely at one with "G. W. S." in the advocacy of fresh stock, especially in the field, for here, as a rule, the methods of cultivation are so far removed from those of the garden that unless fresh material is sometimes employed there is a loss of the necessary stamina to carry them through.

Here we have an alternation of light and heavy soils, the Potato land being governed by rotation of the Corn crops, yet despite this frequent change of soil seed changes are just as strictly necessary to keep up the standard of crop and quality. In some land it is really marvellous how few sorts are found absolutely to suit its nature, and in others it is equally curious that any Potato will adapt itself. To show the adverse nature of the season my case, which is one of many, reveals a startling depreciation when it is said that from the same extent of ground this year there was an average of less than four tons to the acre, while last year there was four times the quantity. Against this must be placed a higher cost of cultivation due to wet weather and weeds. Disease has given trouble in that ground most

HOHERIA POPULNEA IN THE TRINITY COLLEGE BOTANICAL GARDENS, DUBLIN.

their base resting upon a bed of turf loam mixed with decayed manure. Should the bed exceed the temperature indicated, slightly draw the plunging material from the pots in order to lower it. Start the canes in a mild temperature of 50° at night with an increase of 5° by day; create the needful atmospheric moisture by occasionally syringing the canes, &c., with tepid water, and keep the soil moist.

#### LATE VINES.

At this season of the year, when the leaves of late Vines are falling, and the weather is usually damp and changeable, Grapes often keep badly, especially so those that are imperfectly ripened. Keep as far as possible an equable temperature of 50° by the assistance of artificial heat, expelling

Thomas Smith, of Daisy Hill, Newry; it is at present 10 feet or more in height, and has flowered freely during the past two years. The illustration herewith, from a photograph by Mr. George E. Low, of Kings-town, gives a good idea of the flowers and foliage. The plant is malvaceous in structure, although facially it does not look at all, or in any way like a member of the Mallow or Hollyhock family. According to the illustrations of this species, and two or three of its forms in Kirk's "The Forest Flora of New Zealand," the plant at home varies considerably, and I am glad to say that Mr. Smith was

PEAR CHARLES ERNEST, SHOWING ITS FRUITFULNESS AS A YOUNG TREE.

heavily manured. Presumably the lightness of the Potato crop is due entirely to the cold and sunless season, certainly not because of the absence of root moisture nor by reason of late frost cutting down the growing tops. This happened in the garden with early plantings, but not in the field. The short period of extreme summer heat prevailing in July had a paralysing effect on vegetation, following as it did on such a long term of cold, and Potatoes are as keenly sensitive to such changes as are most crops. To the check from this, in part, I attribute the smallness of the sample and lightness of the crop, and they are causes over which we have no control.

Rout Ashton, Wilts.

W. S.

#### TOMATO CULTURE FOR MARKET.

THE culture of the Tomato under glass for market has now assumed enormous dimensions both in England and in the Channel Islands, Guernsey especially, where a great part of the island is given up to glass houses erected for this purpose. The first principle for the grower to consider is that of economy, that is to say, to find out how the best results can be produced at the least possible cost. Experience has shown that this can well be accomplished by following three systems of culture. Firstly, in conjunction with Chrysanthemum culture; secondly, along with that of the Vine; and, thirdly, growing Tomatoes alone. The first named method is largely practised by market growers, and is found to be most convenient, the Chrysanthemums occupying the houses during

winter and the Tomatoes during the summer months.

The glass houses may vary in width and length. For summer crops those 25 feet wide are found suitable, while the length may be anything from 100 feet to 300 feet, according to the land at disposal. The side walls of these houses should be at least 4 feet high, and the apex 12 feet high. For early and winter crops smaller houses should be erected, say 12 feet wide and 8 feet high, and if sunk in the ground 2 feet or so much advantage as regards warmth will accrue.

Winter and spring Tomatoes are best grown in pots and trained to a trellis near the roof. The houses should be built in an open position well exposed to the south and west, and protected if possible from cold north and east winds by hedges, planted not too near, or by some other means available. The question of soil is very important when one determines the position in which the houses are to be built. If this is not present of fair depth and good quality, the value of the land is very much discounted, for if the houses are built on poor land money will have to be spent in buying good soil. The question of drainage also is very important; if the land is not well drained

this will be the first essential work to claim attention. A distance of 18 inches between the plants throughout the house is found suitable. The house should be ready for planting the last week in April, and the plants by then should be 12 inches to 18 inches high, strong and sturdy, and with the first embryo fruits formed. To produce such plants seeds must be sown in January. The number of plants grown will of course be governed by the number and extent of houses to be planted. As soon as the planting is finished each plant should either be staked or string should be fastened at one end to a peg driven in the border and at the other end to the roof; to this string the plants may be loosely tied as growth progresses. Little or no fire-heat will be necessary during the day, but the night temperature must not fall below 55° Fahr. The grower's daily work now will be to do all in his power to bring about a hardy and healthy growth by providing the conditions most likely to ensure this by careful ventilation and watering. On bright sunny days air may be admitted freely consistent with the maintenance of a generous growing atmosphere of from 65° to 70° in the middle of the day. When a good set of fruits is secured, and the border is well filled with roots water must be given abundantly, and manure water at every alternate watering. Until a good set of fruit is obtained air must be liberally admitted daily, and in order that a good crop of fruits may be had the grower should pass a small soft brush or rabbit's tail over each of the flowers. A good average set would probably be secured at such a favorable time of year without

this precaution, but by following this practice a much heavier crop will be had. When the fruits are formed and one wishes to force them, the plants may be given a higher temperature, especially in the afternoon after closing the house. The lateral shoots should be trimmed at least twice a week, keeping the plants always to one stem only. After a time, when the fruits are swelling freely, a top-dressing of fresh soil, with which manure has been mixed, will greatly strengthen the plants and improve the fruits. By the end of summer the plants will be 6 feet high or more, and then they should be stopped, for any fruit which might afterwards be set would not be worth waiting for. How many pounds of fruit a single Tomato plant is capable of producing is a question difficult to answer, and would be replied to alike by hardly two growers. More than twenty pounds per plant have been recorded, but this is quite exceptional, and a yield of eight pounds per plant may be considered the average. A. P. H.

#### THE FRUIT GARDEN.

##### PEAR CHARLES ERNEST.

**O**N December 4, 1900, this, one of the most promising of recently introduced Pears, was shown by the raisers, Messrs. James Veitch and Sons, Limited, Chelsea, before the fruit committee of the Royal Horticultural Society, and then received an award of merit. It is of continental origin, and, although it has been grown in this country for some few years, is comparatively little known. It was shown at the great Pear conference at Chiswick, 1885, by the late Mr. Shepperd, who sent it from Wolverstone, Suffolk, and it was then thought highly of, but seems since to have lapsed into obscurity. Pear Charles Ernest both grows freely and bears heavily, as will be seen from the illustration, which was prepared from a photograph taken in Messrs. Veitch's Langley nursery. It is equally good as a cordon, bush, or pyramid. The fruit is not unlike Doyenne du Connice, it is large, and of good quality; the tree is of distinct habit of growth, forming an erect pyramid, and bears well on the Quince stock. This Pear is in season from October to December.

##### SOUTH AFRICAN FRUIT CULTURE.

(Continued from page 250.)

THERE has been no attempt to grow fine Grapes for dessert, though the climate is perfectly able to do so, as glass in this country is quite superfluous. The farmers have been strongly urged to do so by the agricultural associations of Cape Town, as there would be good markets for them in the large towns.

A slight stimulus to such occurred in 1897 by the improvement of other dessert fruits, and table Grapes were in demand; but there was no enterprise among the growers. Mr. Eustace Pillans, the Government agricultural assistant, hoped to see the two objects well kept in view in the culture of Vines, and urged the matter in his report, but up to the present year (1902) nothing whatever has been done. The bunches often grow to a great size, but as the berries are never thinned they remain as small as marbles and densely packed together.

In 1886, the phylloxera began to be troublesome, and the Government took steps to arrest its progress by means of bisulphide of carbon; but it was only partially effective, so that in 1893 the phylloxera acquired a footing, and severer measures were adopted in abolishing the old Vines and introducing American stocks. With regard to bisulphide of carbon, it was

found that the "killing" dose on rather dry hilly slopes, with a soil of granitic loam, was 240 c.c. for each Vine, occupying 16 square feet, in which twelve holes were made, and 20 c.c. inserted. The vapour passing through the dry soil killed the insect. If the soil was moist, 300 c.c. had to be used. The more effectual and permanent remedy was seened by the introduction of the American Vines. The Government raised many thousands of cuttings for distribution among the Vine farmers.

The following are the varieties which Mr. Pillans records in his report for 1899 as having proved themselves to be the best

#### AMERICAN VINES.

1. No American Vines were found to be under the influence of the phylloxera.

2. The Riparia, when planted in suitable soil, has given entire satisfaction, and should be used in preference to any other kind in such soil. Vines grafted on Riparia are as a rule more productive, but less vigorous, than the same kinds on Rupestris, Aramon Rupestris, and Jacquez.

3. The Rupestris, whether Metallica or any other kind, is only a partial success, as in heavy, damp, low-lying soils, with water in the under-ground, which can be reached by the roots, this Vine is liable to die towards the end of summer, sometimes in alarming quantities. This tendency decreases with the years and with grafting. In very dry soils Rupestris seems to suffer from drought, and is certainly inferior to Aramon Rupestris. For Hanepoot, Rupestris is an unsuitable graft-bearer in the great majority of cases, whereas the other varieties do well, grow stronger than on Riparia, but are less fertile in good land, requiring longer pruning.

4. The Aramon Rupestris is the strongest growing variety of American Vines used in the Colony; its adaptation to all kinds of soil is exceptionally great, and it grafts well, but bears the Hanepoot worse than Rupestris.

5. Jacquez is so far the only variety upon which Hanepoot has been in a number of cases successfully cultivated for over seven years, and there is no reason to doubt its usefulness in this direction.

6. American Vines require generally, on account of their great fertility when grafted, a better treatment, including cultivation of land, drainage, manuring, planting at not less than 5 feet, less topping, and where trellising is practicable it commends itself to strong growing varieties.

It is interesting to observe that the first introduction by the Cape Government of Vine stocks from America were received with almost complete incredulity and coldness. Thus, of the million cuttings distributed gratis by the Government not one-tenth received the smallest attention.

In his report for 1893 the Agricultural Assistant for Stellenbosch, Mr. C. Mayer, observed: "On the whole the reconstitution and renewing of vineyards is progressing slowly. It is true a good number of American Vines have been planted, but a few only have been grafted, and very few have been added to the number of 1892. This slow progress is greatly due to the aversion which exists among farmers to the undoubtedly expensive operation of grafting. Many of them think, on the strength

of the resolution passed last session in the Legislative Council, that the production of grafted American Vines would be soon taken in hand by Government, and that they would then be able to purchase such Vines at a reasonable figure."

At the present day the farmers have realised their folly. Quietly, and perhaps mainly by imitation of their more intelligent neighbours, the average wine farmer has now got his own "mother plantation."

The season of 1900-1 was very unfavourable, in consequence of the dull and rainy weather in January, that month and February being normally the driest in the year. Consequently the Grapes were deficient in sugar, so that many growers converted more or less of their output into brandy. The Government produced at Constantia barely one-half of the usual quantity.

The vintage of 1902 promises to be a "record year" (March, 1902).

(To be continued.)

#### PROTECTING BUSH FRUITS.

THE question of protecting bush fruit trees from the ravages of birds and the effects of frost is an important one to the gardener, and very often the quantities of fruit gathered depend largely upon whether efficient protection has been afforded or not. The old-fashioned method of throwing fish nets over Currants, Gooseberries, and Strawberries is to some extent protective, but it leaves much to be desired. Birds can easily reach the fruit through the meshes of the net, and the work of gathering the fruit is made very troublesome. The nets have to be removed and replaced each time fruit is required, which means a considerable loss of time, to say nothing of the damage done to the nets by tearing.

The accompanying illustration shows a system of protecting bush fruits, immeasurably superior to the one just mentioned. A permanent wooden framework is erected completely encircling the plantation to be pro-

tected, and a covering of close-meshed wire netting is then fastened to the wooden stakes. It is, of course, quite simple to arrange an opening at each of the corners of the enclosure to allow of the admittance of workers. Ordinary fish netting may be made use of instead of wire netting, if the latter is found to be too expensive. Such a covering as is illustrated protects the plants from frost in the spring when they are in bloom, and in the summer from birds when the fruits are ripe. A man can conveniently make his way about beneath the net, and fruit picking can be accomplished with ease and despatch. In the case of Currants and Gooseberries the erection might remain for many years—as long as the fruit trees themselves, in fact—but with the Strawberry this, of course, would not be practicable. Strawberry plants are not retained after they are three years old, and when the plantation was destroyed the framework and covering would have to be transferred elsewhere. Supposing fish netting to have been used, this would not be a serious undertaking. In view of the fact that the Strawberry plantation is not in one place for more than three years, it would be well always to make use of fish netting, leaving the wire netting to cover the Currants, Gooseberries, &c.

#### CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

#### CUTTING THE FOLIAGE OF HARDY PLANTS.

[TO THE EDITOR OF "THE GARDEN."]

**S**IR,—I have been much interested in this question, which is one I have devoted some attention to for years. In the main one must agree with the opinion that cutting off the stems and leaves quite close to the ground is injurious and weakens the plant. It is frequently done for the sake of tidiness, but this is as bad as cutting off the leaves of bulbous plants before they have

THE MOST SATISFACTORY METHOD OF PROTECTING BUSH FRUIT TREES. (IN SYON HOUSE GARDENS.)

ripened. Of course some herbaceous plants will throw up fresh foliage the same season, but one would understand that this constitutes a strain upon the resources of the plant. There are, however, some plants which appear to suffer little from having their foliage cut off close to the ground when the flowering is over. I know of one garden where *Papaver orientale* and the old double *Peonia* have been cut down in this way for many years, and yet have continued to bloom as freely as before. I have put in a plea for the *Peonia*, and it has been left uncut this season for the first time, and I anticipate that there will be an improvement another year, though it is hardly possible to conceive that larger flowers can be produced. The Oriental Poppy is almost impossible to destroy, so that one thinks less of its hardihood under such treatment. My own practice is to allow the plants to ripen their foliage, and only to cut the stems far enough back to make them less obtrusive until the leaves have ripened.

S. ARNOTT.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Adverting to the discussion on this subject, it seems to me that much depends upon the plants themselves. Most of the perennial Asters, except the *Amellus* section, may be cut down as soon as shabby with impunity, because in their case the new growths are well advanced by the time flowering is over. The same with late Phloxes. The early ones I only shorten so as to keep the plants growing and perfecting the basal shoots.

Delphiniums I only shorten by cutting off the tops that carry the seed pods; I look upon them as semi-tuberous, and think the roots require the majority of their leaves left on to ripen them. So do the tall Campanulas, such as *C. latifolia*. *Antirrhinums*, on the other hand, will grow again readily if the stems be cut close to the base, where there are generally a number of young shoots.

So that, after all, it appears to come to this, that those plants may be cut down which start new growth while the plants are blooming (*Monardas* and *Harpaliuns* are other instances), and those should not which have their new stem-buds dormant until the next season of growth is approaching. It may, of course, be said that Delphiniums form their new stem-buds while the old shoots are blooming. So they do to a certain extent, but to force the plants to make two sets in a season must surely put too great a strain upon them for their permanent welfare.

Thirlwood.

T. J. WEAVER.

PEAR DIRECTEUR HARDY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—It is seldom that one would venture to recommend confidently a Pear on the experience of a single crop, but as this present season is notably one in which flavour in Pears is deficient, I make bold to advise all Pear fanciers to plant at least one tree of Directeur Hardy. We are eating it now, and it is superb in flavour, of good size, neither too big nor too small. Its flavour is suggestive of both *Chaumontel* and *Lonise Bonne*. Coming a week or two before Comice is ready it is most acceptable, and, although we already have so many October Pears, I know of none to equal Directeur Hardy as it now is with us. Ours were grown on a wall, but I am confident from its growth that it will also do well as a bush, in the South of England at least.

W. WILKS, Vicar of Shirley.

GRAPES FOR EXHIBITION.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—While reading the very interesting article on the above subject by Mr. Owen Thomas (page 269) a thought occurred to me which I should like to place before your readers. In describing Black Alicante, Mr. Thomas says this variety is easy of culture. Now, we hear this remark so often, and we know that in the opinion of most judges this variety is considered so easy to

grow, that it ought not to count so high as most others that may be placed in competition against it. To call it in question may seem nothing short of presumption on my part. I think it will be generally admitted that perhaps the two best known and most successful exhibitors of the day are Mr. Kirk, of Norwood, and Mr. Lunt, of Keir. A singular fact connected with these two growers is that both have been very successful in the cultivation of those varieties generally considered most difficult to grow. Mr. Lunt excels in the culture of Mrs. Prince, Muscat Hamburgh Muscat of Alexandria, Alnwick Seedling, and Black Hamburgh. It sounds strange to include the latter amongst difficult sorts, for is this not the Grape we recommend all amateurs to grow? Yet a perfectly finished bunch of Black Hamburgh is as rare as a finely finished Muscat of Alexandria. Mr. Kirk, again, grows Madresfield Court, Duke of Buccleuch, and several other "kittle" sorts very well. The Duke I consider the most difficult of all to do well, as it is one of the most handsome and imposing when well grown.

I do not remember a single visit to Mr. Kirk—and I have paid him many during the last twenty years—in which I did not see most remarkable examples of this Grape in some or other of his vineeries. Now, the question I wish to ask Mr. Thomas and those who think with him that Alicante is so easy to grow is, How is it that these two experts, Mr. Kirk and Mr. Lunt, are not successful with this variety? In all Mr. Lunt's victorious career I do not remember his staging a single bunch of Alicante in any of his collections, and I certainly never saw a creditable exhibition bunch of this variety at Keir. Only once do I remember Alicante being shown by Mr. Lunt, and that was in the class for this variety, and then he got second prize. The same with Mr. Kirk: he has not shown this variety, so far as I remember, since the last International Show held at Edinburgh, and not for many years, amongst all the many fine Grapes he grows, have I seen a creditable bunch of Black Alicante. The fact is this variety does not do well either at Keir or Norwood, and why should it fail in the hands of two such experts, when it is so easily to cultivate, is a question I leave others to answer.

Scotland.

A GRAPE GROWER.

## INSECT PESTS AND THE FRUIT CROPS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—With the excellent notes from the pen of "G. H. H." (page 237) concerning the methods of combating insect enemies in the garden and orchard many will agree. That insects are left severely alone in hundreds of cases is quite true, and such instances must from force of circumstances continue. There is no limit to the good, useful, and cheap insecticides on the market, and this season instances are not wanting where fruit plantations, private and market, have been made odorous by the repeated applications of quassia to stay the determined attacks of the aphis family on fruit trees. It has been often repeated that gardening is an expensive hobby, and in a great measure it undoubtedly is; where regarded in this light, the gardener has almost invariably to place a limit on the purchase of necessary commodities for use in the garden. Then, again, restraint of labour involves other hardships, which often are such that they cannot be surmounted, although much more could often be done than is done, and an investment in a good insecticide is well laid out. Fruits of any kind, if the trees become infested with aphis, will most assuredly fall prematurely. Such instances bring with them their own reward.

"G. H. H." is inclined to regard the winter moth caterpillar as a friend in disguise. This, after the oft-repeated pressure brought to bear on the necessity of early extermination, is a move in a new direction. There is, however, a good deal of useful logic in such a theory, for in fruitful seasons trees do right themselves somewhat. It often happens, even admitting the truth of this, that the heaviest cropping sorts, or those which

fruit in alternate years through excess of crop, are almost quite free from caterpillar aids, and the more moderate and large fruited ones suffer. London Pippin, Stirling Castle, and Cockle's Pippin are names that suggest themselves as alternate croppers where caterpillars would do a useful work in thinning down their numbers appreciably. What the possibilities of thinning down these small fruiting sorts may be in the market orchard I cannot say, certainly in the undenamed private garden they stand a remote chance of being carried out, much as those responsible may wish.

To both trees and owner American blight is certainly a terrible enemy. If present in any appreciable quantity, anything calculated to rid the garden and orchard of such a dreaded pest is well worthy of practise. Gas tar and petroleum emulsion is a remedy that has found some adherents; so has petroleum alone, and methylated spirit, either of which instantly destroys life when brought into contact with it. Young Apple trees, and especially those growing against a wall, are quickly made cancerous if American blight is long left in possession. The east winds prevailing in the spring were no doubt to a very great extent the cause of the aphis pest on Plum and Apple trees, albeit "G. H. H." speaks lightly of such facts. These and other aphis are believed to be borne on the breezes from distant eastern regions. In support of this, one has only to reflect on the origin of the plagues inflicted on the Egyptian Pharaohs, and there is no reason why cause and effect in Nature should differ now more than in those ancient times. The present season would seem to have been particularly congenial to them, judging from their increase, and that, too, in unexpected places.

Rood Ashton, Wilts.

## CARPETING PLANTS FOR BULBS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—This subject well deserves the remarks made upon it by Mr. W. H. Divers and Mr. S. W. Fitzherbert, and one can only agree as a whole with what they have said on the subject. As Mr. S. W. Fitzherbert says, *Ionopsidium acaule* is an excellent surfacing plant, and is one, also, which is beautiful in itself. On the other hand it is an annual, and is not to be relied upon in the north to perpetuate itself by means of self-sown seedlings as it does in the south. In many gardens, also, where there is a risk of the flowers being knocked over by winds, a taller carpeter is an advantage, as it helps to sustain the blooms. Personally I like to see the tubes of the flowers of some of these bulbous plants, but this cannot be secured with a very close carpeter without the flowers being levelled by the first strong wind, especially when accompanied by heavy rain. Nor can one deny that such a *Crocus* as *speciosus* flowering among grass or through some dwarf plant not so close-growing as the *Ionopsidium* looks very charming indeed. I have this *Crocus* planted pretty freely and in various ways, but I was particularly delighted the other day by some flowers which had sprung up among a clump of *Euphorbia Cyparissias* and had opened in the sun. They were most delightful, and harmonised well with the "fleecy" look of the *Euphorbia*. Of course, *E. Cyparissias* is a plant which must be planted with some discretion on account of its encroaching habits, but the combination was a suggestive one which I hope will be helpful in other ways. For such things as spring bulbs of the character of *Snowdrops*, *Scillas*, and the like I find that *Saxifraga Cymbalaria* is a capital thing. One drawback the taller carpeters often have for a garden troubled with slugs is that they harbour these pests, which are exceedingly fond of the autumn *Crocuses* and often injure their beauty. Some of the smaller *Crocus* species seem, however, to object to being carpeted with any but the most surface-rooting plants, but such vigorous species as *speciosus* or the *Colchicums* have no difficulty in this respect. The *Acænas* are good carpeters for the *Colchicums* of dwarfer stature than the great *Colchicum speciosum*.

S. ARNOTT.

## BOOKS.

**In a Tuscan Garden.**\*—The writer of this very pleasant book does not publish her name, but the book itself reveals her to us as a *grande dame*, with all the refined instincts of her caste, and, withal, as a shrewd, kindly, and thoroughly capable woman of the world. She tells us how she has reclaimed a neglected house and garden of moderate size, the appanage of a large villa and park near Florence; also of her domestic and horticultural experiences during a residence of fourteen years, with many interesting sidelights on the character of Tuscan neighbours and dependents. Readers of the book will feel themselves agreeably in touch with a vigorous personality that is thoroughly in sympathy with the best aspects of gardening.

**The Silva of North America.**—The publication this autumn of volumes XIII. and XIV. of Professor Sargent's "Silva of North America" completes this exhaustive and monumental work, which has been twelve years in preparation. The illustrations comprise 750 plates, engraved in Paris from drawings by C. E. Faxon, and adequately represent 567 different species of American trees north of Mexico recognised by botanists. Professor Sargent, Director of the Arnold Arboretum of Harvard University, is widely known as the highest authority on the subject he treats. The

"In a Tuscan Garden." Published by John Lane, London and New York. 1902.

last volume contains an index to the entire fourteen volumes. To those who subscribed for the first twelve volumes prior to June 1, 1901, this index volume will be furnished without charge, and volume XIII. for 25dols. The work is sold only in complete sets, and the price for the fourteen volumes will henceforth be 350dols. net. No cost or pains have been spared in the mechanical execution of the work, which must always remain a standard on the subject which it treats. To the public libraries in all parts of the country it will be indispensable, and in many private libraries it must command an immediate place. Specimen pages and a sample plate will be submitted upon request. The address is Messrs. Houghton, Mifflin, and Co., 4, Park Street, Boston.

**Journal of the Royal Horticultural Society.**—No periodical publication is more welcome than the Journal of the Royal Horticultural Society, and this new volume contains a vast storehouse of information freely and judiciously illustrated. It contains no fewer than 368 pages, apart from the reports of the committees and "Notices to Fellows." The first paper is about "Fungoid Pests of the Garden," with coloured illustrations, by Dr. Cooke, followed by one upon such a practical subject as "Renovation of Old Fruit Trees," by Mr. George Bunyard. Two of the papers were given at the Horticultural Club, a most interesting one by Mr. Charles Pearson on "Birds *versus* Gardening," and "A Cape Garden" by Mr. H. M. Arderne. The Campanula paper by Mr. Prichard is profusely illustrated, and this can be said of almost all the

subjects. A paper that will please greatly is called "Plant Communities," by Professor Carr, and charmingly illustrated with flower groups. That of "Sea Holly, Sea Bindweed, and Yellow-Horned Poppy on Wicklow Coast" is very beautiful. Amongst the contributors to this volume are Miss Jekyll, "Pergolas in England," and the Hon. Mrs. Boyle ("E. V. B."), "Weeds of the Garden," whose articles we hope to publish shortly. We always turn with interest to the "Commonplace Notes by the Secretary and Superintendent." Here is one about destroying wasps: "All fruit growers are only too well acquainted with the ravages of wasps amongst fruit, the damage seldom ending with the wasp, as flies and other insects follow and feed through the holes in the fruit made in the first instance by the wasps, until little is left save the outside skin or husk. There are many methods of keeping down the number of wasps, all more or less unsatisfactory, and there is no doubt that the best means of minimising their evil effects is to destroy all the nests. When the wasp has visited the fruit and secured all it requires it always flies in a straight line for its nest, and a sharp-eyed boy will quickly locate all the nests in the neighbourhood by following this line of flight. Having discovered the nests, it is a very simple matter to take some cyanide of potassium and put a little—say half a teaspoonful—into the mouth of the hole leading down to the nest. Most of the wasps that are really troublesome are *Vespa vulgaris*, and build their nests in the ground, so that there is no difficulty about destroying the nests, as every wasp that passes

NELUMBINUM SPECIOSUM IN A JAPANESE GARDEN.

over the cyanide of potassium is killed by the fumes as it passes in or out of the nest. For this reason we prefer to place the cyanide in the mouth of the hole during the daytime, for when placed there at night when the wasps are at rest much of its strength has evaporated and is lost before the wasps are active in the morning. There is no danger of being stung if the person destroying the nests walks quietly up to the hole and places the cyanide of potassium carefully in and moves away again quietly without beating at any wasps that may be buzzing about him. We have destroyed hundreds of nests in this way without once getting stung. "Cyanide of potassium is a deadly poison, and should only be used by a careful person, nor should it be left about where children could get at it. It is far more effective and expeditious than tar, gunpowder, or any other means for destroying wasp nests." There is not the slightest doubt that the remarkable increase in the number of Fellows is owing to the excellence of the Journal. No society in existence gives so much for the small sum needful to become a Fellow. It is a thoroughly good investment.

**Thompson's Gardener's Assistant.**—With volume VI. this work, in its revised form, concludes, and the editor—Mr. W. Watson, Curator of the Royal Gardens, Kew—must be congratulated on the success of his efforts to make this valuable book as practical as possible to all who are interested in gardening. His assistants are men well known in the world of horticulture, and the illustrations are profuse and excellent. This volume has for a frontispiece a well-reproduced coloured plate of hardy Water Lilies, and two other coloured plates are also given, namely, of Aubergines or Egg-plants (seven varieties) and Anthurium scherzerianum, which we regret to see sandwiched in the important "Calendar for the Fruit and Kitchen Gardens": it seems out of place, but this is a small blemish. The volume deals with the kitchen garden, and the information is sound and practical. There is no better book for a gardener's library than this, and the amateur can learn much from its well-printed and illustrated pages.

## ORCHIDS.

### NOTES FROM CLARE LAWN.

**A**MONG the southern collections of Orchids that of Sir Frederick Wigan, Bart., of Clare Lawn, East Sheen, stands out conspicuously. Southerners are very proud, and justly so, of this collection of Orchids, and of those made by Baron Schröder, Sir Trevor Lawrence, and Mr. R. H. Measures. In all of them the plants are well grown. This collection deservedly ranks among the best. Its excellence is testified to by the numerous certificates gained at the Royal Horticultural Society's fortnightly meetings and by the splendid groups annually exhibited at the Temple Show. A special triumph must be recorded for 1901, as the Sherwood Cup, then offered for the best exhibit of Orchids, was gained by the Clare Lawn plants, arranged in what was perhaps one of the most striking and beautiful groups ever seen. A unique feature in this collection is the Cymbidium house, a lofty structure tastefully built up with walls and pillars of tufa, in pockets of which are huge specimens of Cymbidiums lowianum, giganteum, eburneum, hookerianum, tracyanum, and equally fine plants of such hybrids as eburneo-lowianum and the reverse cross, winnianum, l'Ansoni, and the rare wiganianum. The rockwork is practically covered with Adiantums and Ficus. It is difficult to convey an adequate idea of such a house when the plants are in full bloom. Even now, at this

dull season of the year, the foliage and Ferns render the house attractive, and already numerous stout flower-spikes, peeping between the thick green leaves, give promise of the display to come. Next to the Cymbidium house is a partially-sunk span-roof house devoted chiefly to Phalaenopsis, Cypripediums, and Vandals. The culture of Phalaenopsis has evidently been thoroughly mastered by Mr. Young, the Orchid grower. Some of the plants have been in their present quarters for the last eighteen years, and have stout leathery foliage, in spite of the winter fogs, which are, unfortunately, but too prevalent in this locality. Vigorous as the plants are, several have been placed in leaf-mould to see if further improvement be not possible. So far the experiment is a success: several spikes were noticed on plants of amabilis, stuartiana, sanderiana, &c. In the same house is a batch of Anectochilus dawsonianus, a picture of health and beauty. They have the protection of a hand-light, but apparently are accorded no special treatment. Eulophiella Elizabethae also finds a corner in this house, and is luxuriant in growth. A plant of the interesting Bulbophyllum grandiflorum was in bloom, the large flowers attracting notice, though not brilliantly coloured, from their quaint structure and exquisite reticulated markings.

The Cattleya houses contain a comprehensive selection of species. In the largest Cattleya house attention is arrested by the numerous spikes rising from a batch of Laelia anceps. Close inspection proves the majority to be whites, including such varieties as Dawsonii, sanderiana superba, Hillii, alba, Stella, &c. A useful and effective display will doubtless shortly be obtained. The warm house contains a grand lot of Dendrobium formosum giganteum in full flower, the huge white and orange-yellow blossoms being very conspicuous. Dendrobium Phalaenopsis schoderianum in flower and bud also adds to the display. These two species, though in different sections, are certainly among the most effective in the genus. Other occupants of the house include well-grown Selenipediums, Vanda batemanniana, a useful batch of Cypripediums, among which is the rare and beautiful Cypripedium Muriel Hollington (C. niveum × C. insigne). It may be mentioned that Cypripediums niveum, concolor, bellatum, and Godefroyae are particularly well grown at Clare Lawn, a position being given them to the glass.

An interesting plant, Scuticaria Hadweni, was in flower, carrying seven of its curious greenish yellow, pale yellow, white, and chestnut-blotted blossoms. Scuticarias are seldom met with among present-day Orchids, hence the presence of this old-time favourite in such an up-to-date collection is all the more noteworthy. The cool houses include a number of Masdevallias, chiefly hybrids, varieties of harryana, and such rare but attractive species as Schlimgii, trochilus, reichenbachiana, schröderiana, &c., together with Maxillarias, a few Pleurothallis, including a grand specimen of P. Roezlii. A side stage is devoted entirely to Miltonia vexillaria, among the plants being some exceedingly rare and choice forms.

The Odontoglossums are a particularly healthy looking varied lot of plants, and include several magnificent varieties of Odontoglossum harryanocrispum, O. Kolffii, O. lochristense, &c., numerous grand forms of O. crispum, andersonianum, elegans, &c., in addition to a good selection of the types and more common species. A span-roofed house entirely set apart for hybrid Laelias and Cattleyas, Laelio-Cattleyas, and the finest varieties of the species, contains a very choice collection of well grown plants, many being in sheath. A new and most attractive hybrid obtained from Laelia xanthina × Cattleya Rex, at once caught the eye from its distinct yet soft colouring, a tender shade of butter-yellow, lightest on the margins and in the throat, with, on the centre of the lip, a suffused blotch of purplish magenta. This plant was exhibited at the last Royal Horticultural Society's meeting under the name of Laelio-Cattleya Constance Wigan. A second new hybrid also exhibited at the same meeting from this collection was Laelio-Cattleya Iva, raised from

Laelio-Cattleya schilleriana crossed with Laelia longipes. The latter parent, though producing small flowers, has distinctly influenced the present hybrid, as can be seen from the dark fluted lip, and though by no means equaling the first hybrid mentioned is yet a pleasing Orchid, with sufficient charms to merit a place even in this collection, which, large and varied though it is, is in the pink of condition, and reflects great credit on the able Orchid grower.

ARGUTUS.

## SOCIETIES.

### ANCIENT SOCIETY OF YORK FLORISTS.

THE twenty-third Chrysanthemum Show will be held in the Exhibition, York, on the 12th, 13th, and 14th inst. Numerous special prizes are offered, in addition to many valuable ordinary class prizes. Entries close on Wednesday next.

### IPSWICH AND EAST OF ENGLAND HORTICULTURAL SOCIETY.

THE annual show of this society takes place on the 11th and 12th inst., and will be held in the Public Hall, Ipswich. The schedule is a representative one, including numerous prizes for fruits, flowers, and vegetables.

### LISBURN AMATEUR GARDENERS' SOCIETY.

THERE was a good attendance of members, including ladies, on the 15th ult., at the usual monthly meeting held at the Concert Hall, Mr. Jowett presiding. The exhibits were fresh and bright, although not numerous. "Soils and their Treatment" was the subject for consideration, and was in the care of Mr. R. G. Waterman, of Woolton, who in a clear and lucid manner described the requirements of the various soils, the most desirable positions, how best to form good composts, &c. Special attention was directed to the value of manures, how and when they should be given, mulching in many cases being strongly advised. A few notes on rotation concluded this important subject. Many questions of interest were asked concerning special kinds of soils and the most beneficial manures for them. Suitable replies being given, a hearty vote of thanks was tendered to Mr. Waterman for his admirable address.

### BENFIELD HORTICULTURAL ASSOCIATION.

THE winter session of the above society opened on Tuesday evening, the 14th ult., when there was a very good attendance of members. A most interesting paper was read by Mr. Neve, of Lindleshaw, on "The Renovation of Old Fruit Trees." He dwelt on the importance of keeping old trees in good bearing, and mentioned how he had treated some espalier trees, which, when they first came under his charge, bore small, cankered fruit quite unfit for use. These espaliers had their side limbs cut off close to the main stem or trunk, and the main stem itself headed back. The result was a bush tree, which in two or three years after this treatment furnished an ample supply of excellent, good-sized fruit. Mr. Neve advocated this plan in preference to grafting for old trees of good sorts. Other points in connexion with the subject, such as manure, insect pests, head and root-pruning were ably dealt with. He showed photographs of the trees he had manipulated in the manner described. Several questions were asked and a good discussion followed, in which Messrs. Bungay (chairman), Payne (secretary), Howell, Bushy, Mason, Galliford, and others took part. A hearty vote of thanks to Mr. Neve for his able paper brought the meeting to a close.

### READING GARDENERS' ASSOCIATION.

MORE than 100 members assembled at the last meeting of the above association to hear Mr. George Gordon, V.M.H., deliver a lecture on "Beautiful Flowering Trees and Shrubs." Time did not suffice to give more than a running commentary on a magnificent series of photographs, shown by the limelight, illustrating some typical specimens of the Double Peach, Almond, Magnolia, Cherry, Plum, Quince, Pear, Thorn, Laburnum, Genista, Berberis, Lilac, Deutzia, Viburnum, Exochorda, Spiraea, Hydrangea, Horse Chestnut, Catalpa, Wistaria, Azalea, Heath, Andromeda, Rhododendron, &c. The exhibits were exceedingly interesting, the honorary ones were: A basket of Princess of Wales Violets (splendid blooms), retarded Potatoes (illustrating the method of obtaining young Potatoes all the year round), also a dish of fruit of Psidium cattleianum (Guava), suitable for dessert or jelly, by Mr. G. Staoton, Park Place Gardens, Henley-on-Thames; a collection of Sweet Peas by Mr. D. Ager (gardener to Milton Bode, Esq., Caversham). For certificate, a batch of Michaelmas Daisies grown as annuals, seed sown in February, planted out in June, and potted up in September (certificate awarded), by Mr. F. Lever, The Gardens, Hillside, Reading, and a magnificent specimen of Orchid, Odontoglossum grande (certificate awarded), by Mr. W. G. Pigg, The Gardens, Treveroli, Maidenhead. A hearty vote of thanks was accorded to Mr. Gordon, on the proposition of the president, for his interesting lecture. Four new members were elected.

### BECKENHAM HORTICULTURAL SOCIETY.

ON Friday, the 24th ult., at the Church House, a lecture was given by Mr. W. Groves, Grove House, Shortlands, on "The Growth and Cultivation of Mistletoe." Mr. G. N. Hooper, F.R.G.S., occupied the chair. The lecturer stated that the best trees for the cultivation of Mistletoe were the Apple, Willow, Pear, Poplar, Lime, and Oak, but it is

\* "The Gardener's Assistant." By Robert Thompson. New edition. Revised and entirely remodelled under the direction and general editorship of William Watson, Curator, Royal Gardens, Kew. Price 8s. London: The Gresham Publishing Company, 34, Southampton Street, Strand.

rarely seen on the last-named, only about six Oak trees in England are known as bearing Mistletoe. The seed thrives best by being sown on the same kind of tree that it was taken from, e.g., if taken from an Apple it is best to sow it on an Apple. The most successful method of sowing is not, as most people imagine, by making an incision in the bark of the tree and placing the seed therein, but simply by placing the seed directly on the branch of young wood, the gummy substance around the seed prevents it from falling or being blown off. The best time for sowing is the month of March, as the seed is then mature, and in a few weeks the seed throws out roots into the bark, and that is the extent of the growth for the first year. The second year it throws out two leaves, and the third year it grows from half an inch to 6 inches, after which the growth is fairly rapid. If by any chance the plant is broken off it will throw up in another part of the branch, thus showing that it is pretty hard to kill. The theory of Professor Darwin that the seed of the Mistletoe must pass through the stomach of a bird before it will germinate was flatly contradicted by Mr. Groves, who by personal observation has proved that a seed having passed through a bird is digested, and not a vestige of it remains. Mr. Groves exhibited some remarkably healthy-looking specimens of the plant from the time they were first sown until sixteen years old, some growing on dead wood. A good discussion followed, in which Messrs. Hooper, Webster, Harman, Price, and Randell took part. Mr. Webster showed some excellent Strawberries and Raspberries. A vote of thanks to the chairman and lecturer closed a very successful meeting.

GEORGE EXTER.

## LONDON DAHLIA UNION.

A MEETING of supporters of the above society will take place at the Royal Aquarium, Westminster, on Tuesday next (the first day of the great exhibition of the National Chrysanthemum Society) at four o'clock p.m., in the gallery dining-room. A statement of receipts and expenditure duly audited will be submitted, and a report from the chairman and secretary to the effect that they have arranged with the directors of the London Exhibitions, Limited, Earl's Court, West Kensington, for the exhibition of the London Dahlia Union to be held in the Prince's Hall of the Exhibition on Wednesday and Thursday of the third week in September. The directors of the Earl's Court Exhibition have met the suggestions of the chairman and secretary in the most liberal manner, and it is certain that a very fine exhibition may be anticipated.

## NATIONAL CHRYSANTHEMUM SOCIETY.

At a meeting of the classification committee, held at the Royal Aquarium on the 7th ult., Mr. Norman Davis was elected chairman of the committee. It was resolved that the following two varieties, Lily Mountford and Hilda Chamberlain, be bracketed as synonymous in the society's list of two much alike Japanese varieties. That the following be bracketed as synonymous in the lists of too much alike early-flowering varieties, Harvest Home and Cranford Beauty. That the following Pompon varieties, Martinmas, La Vierge, and Vesuve, be transferred from the early-flowering Pompon section to the early large-flowered section. It was further resolved that the heading in the society's catalogue, "Japanese Early-flowering Varieties" be altered to "Large-flowering Early Varieties," so as to include all types except Pompoms. That a new class be added to the society's catalogue, now in course of compilation, to embrace market and general decorative varieties other than early-flowering.

## CARDIFF GARDENERS' ASSOCIATION.

ON Tuesday, the 21st ult., a meeting took place at the Grand Hotel, when Mr. C. E. Collier presided over a large gathering of members. Mr. E. W. Treseder, F.R.H.S., delivered a highly interesting lecture, entitled "Budding, Grafting, and Layering." Several specimens of buds and grafts were brought to the meeting, which the lecturer used by way of making his subject more easily understood. After a lecture of more than an hour's duration, an extremely interesting debate took place. A very cordial vote of thanks was accorded Mr. Treseder for his splendid lecture, to which he suitably responded. Several new vice-presidents and members were enrolled.

## WORCESTER COUNTY COUNCIL FRUIT SHOW.

THE second exhibition of agricultural and horticultural produce, arranged under the auspices of the Agricultural Sub-Committee of the Worcestershire County Council at the Shire Hall, was opened by Sir T. H. Elliot, secretary to the Board of Agriculture, on the 18th ult., and proved in every way a success. Of course in the horticultural section the bulk of fruit exhibited cannot in any way be compared to that of the exhibition held in 1900, yet the quality was on the whole decidedly good. From an educational point of view this exhibition proved most instructive, because it was the first of the kind in England where the fruit was classified in respect of soils, thus showing definitely the effect of soil upon the flavour, quality, size, and colour. The object of holding the exhibition was chiefly to ascertain under what conditions as to soils, locality, varieties, stocks, cultivation, and treatment the fruit was grown, and this object was fully achieved. Exhibitors were provided with cards on which they were asked to state the details just mentioned, while soils were divided into three kinds, light (including sandy, gravelly, and brashy, two-horse ploughing), medium (including sandy loams, marls, light clay loams, three-horse ploughing), and heavy soils (including strong clay loams, clays, and peaty soils, four-horse ploughing). Space necessarily prevents us from giving full details of all the exhibits which received certificates, and we will therefore only mention a few of the most meritorious.

Amongst Apples, Worcester Pearmain, although rather undersized, was well shown by several exhibitors. The

best dish (five specimens) came from off a medium loam, and were exhibited by General Davies, Elmley Castle, near Droitwich. Cox's Orange Pippin was not up to the usual standard, but there were some capital dishes of King of Pippins, the best being shown by Mr. W. Crump, Madresfield; Admiral R. F. Britten, Kenswick, Worcester (medium soil); and Mr. T. Amphlett, Brookhampton, Ombersley, Droitwich (medium soil). Ribston Pippin seems to have failed generally, and in point of fact does not seem to flourish well in Worcestershire, owing to canker. The best dish came from Mr. T. Amphlett, but only a second-class award was given. The class devoted to Blenheim Orange brought forth some really splendid exhibits, Admiral Britten's fruit especially being of large size and very highly coloured, while other meritorious exhibits of this variety were contributed by Mr. H. Gabb, Sandlin, Malvern; Mr. A. N. Ganderton, Rous Lench, Evesham, and Mr. W. Drew, Butt's Farm, Broadway. Warner's King is a variety much favoured by Worcestershire growers, and a large number of dishes of this variety were staged. A very even and remarkably well-grown sample came from Mr. A. N. Ganderton, and also from Admiral Britten. Other exhibitors who showed this variety in capital condition were Mr. W. Drew and Mr. Amos Randle, Heightington, near Bewdley. Peasgood's Nonsuch was very sparingly exhibited, the finest and best coloured coming from Mr. James Best, Holt Castle, Worcester.

In the class for Lane's Prince Albert, Mr. Crump was easily to the fore with splendid fruit, and a very good dish was contributed by Mr. Alexander Slater, Woodfield, Newland, Malvern (stiff soil). A large number of exhibitors staged Dunnelow's Seedling in good condition, notably Mr. Crump, Colonel Wheeler, Newnham Court (stiff soil), Mr. W. Drew, and Mr. William Lane, Upton-on-Severn. Bismarck was but poorly represented, Mr. H. Gabb and General Davies staging the best dishes. In the class for any other culinary variety not mentioned in the schedule, Mr. Crump staged some extraordinarily fine fruits of Mère du Ménage, though not very highly coloured. These were grown on a standard tree, which crops fairly well, and the fruit cooks well, but does not keep very late. Mr. Crump also exhibited Lord Derby in very fine condition, the fruits being gathered from a tree on free stock. "A good cropper and cooker, and always comes large," is Mr. Crump's report as to the behaviour of this variety at Madresfield. Mr. J. E. Britten, Old Wood, Tebury, was given a first-class award for a dish of that good old culinary Apple Forrester, as shown, a dull green russety fruit, rather flat in shape. Pears were not largely exhibited, but Mr. Crump and several other growers exhibited some good dishes. Mr. S. T. Wright (Chiswick) judged the Apples and Pears, and it is needless to add performed his duties to the entire satisfaction of the committee.

## NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the Floral Committee was held at the Royal Aquarium, Westminster, on Monday last, the 27th ult., when a capital display of novelties was adjudicated upon. Mr. D. B. Crane was in the chair. As usual, Japanese varieties very largely predominated, and among these were blooms of sorts which, it is safe to say, will occupy the attention of all exhibitors. Those to receive awards were:—

*Miss Mildred Ware.*—A very large and handsome Japanese bloom, said to be a seedling from Mme. Carnot. The florets are very long and of medium width, reflexing and drooping in a pleasing way. The colour may be described as a light shade of bronze, slightly tinted rose, and reminds one of nicely coloured blooms of Charles Davis, of which variety it may be considered a much glorified edition. First-class certificate awarded to Mr. T. Bullimore, Canon's Park, Edgware.

*Miss Olive Miller.*—This is one of the most pleasing Japanese novelties of the present season. The flowers are very large, deep, and full, with long and fairly broad florets, which are slightly grooved, they also twist and curl and incurve at the tips, and build up a splendid deep exhibition bloom. The colour is a distinct shade of pale rosy pink on a silvery white ground, and the reverse is also silvery. Later buds give blooms of a deeper colour. First-class certificate awarded to Mr. G. Mileham, The Gardens, Enlyn House, Leatherhead.

*George Penford.*—Another superb Japanese variety, with long and broad strap-like florets of splendid substance, reflexing and curling prettily at the ends. Colour deep rich crimson, with a rich golden reverse. The blooms are large and spreading, and are also very full, and will prove of immense value to exhibitors in succeeding seasons. First-class certificate to Mr. G. Penford, Leigh Park Gardens, Havant.

*Florence Penford.*—This is a fine Japanese incurved bloom. The florets are broad and of splendid substance, twisting and curling and incurving rather tightly, building up a bloom of good size. Colour pale buff, tinted yellow in the centre. First-class certificate also awarded to Mr. Penford.

*Cecil Cutts.*—A large deep incurved bloom, having florets of medium width and pointed, and of good substance. Colour rich yellow. This should prove to be a good back row flower. First-class certificate awarded to Mr. Thomas Mudd, Thorneycroft, Nottingham.

*Rycroft Beauty.*—A charming decorative Japanese variety, developing beautiful blossoms on long erect footstalks, and of pleasing form. Colour soft pink, tinted gold in the centre. A plant was exhibited to show its habit, and this was not more than 3 feet in height, and it was freely flowered. Commendation granted to Mr. H. J. Jones, Rycroft Nursery, Lewisham, S.E.

A vote of thanks was accorded to a North Country exhibitor for a bright yellow sport from early-flowering Pompon Mme. Ed. Lefort. The sport is to be distributed under the name of Gladys Gray, and owing to its colour the plant should prove to be an acquisition.

Other good Japanese varieties were:—Harry Greenfield, a lovely crimson, reflexed Japanese flower of even build, and of a spreading character; this is promising. F. S. Vallis

(Calvat), a very large golden yellow Japanese, very similar to G. J. Warren in every respect; Wilfred H. Godfrey, a rich rosy chestnut-crimson, and bright golden reverse, long drooping florets of medium width, pointed and incurving at the tips, describes its form; Mrs. H. Emmerton, an Australian seedling Japanese, colour rich yellow, slightly suffused buff, having long and even reflexed florets of medium width, building up a large bloom of splendid form, every flower comes well; Henry Perkins, an English-raised Japanese seedling, with long broad strap-like florets, loosely reflexing and making a spreading flower, colour reddish crimson, tinted and slightly suffused yellow, with a golden yellow reverse; Miss Smith, a large spreading flower with chaste characteristics, reminding one of an improved Mutual Friend. The creamy white petals have more substance than those of its prototype.

## PENARTH CHRYSANTHEMUM SHOW.

WE understand there will be no exhibition of Chrysanthemums at Penarth this year.

**Messrs. John Laing and Sons—Dissolution of partnership.**—The firm of John Laing and Sons, nurserymen, Forest Hill, has been dissolved by mutual consent, and the business will in future be carried on by John Alexander Laing.

**Ulster Horticultural Society—Postponement of show.**—The Chrysanthemum show has been postponed till the 25th inst., in order to suit their Excellencies the Lord Lieutenant and Countess of Dudley, who have graciously promised to perform the opening ceremony.—J. MACBRIDE, Secretary, 1, Adelaide Street, Belfast.

## ANSWERS TO CORRESPONDENTS.

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

**Name of Plant.**—J. Henshaw.—Leucadendron argenteum.

**Names of Fruit.**—H. H. M.—1, Probably malformed fruit of Warner's King; 2, Emperor Alexander, cooking variety only; 3, Landsberger Reinette.

**Muscat Grapes unsatisfactory** (J. S. D.)—Judging from the condition of the fruit and foliage by the sample sent, we are of opinion that the roots of your vines are in a bad condition, and that it will be found on examination that many of them have perished from one cause or another: hence the inability of the vine to support and develop a good sound crop of fruit. There is also an indication of scalding or burning of the leaves and berries as well as an attack from red spider. This would be caused by insufficient ventilation during summer and by the condition of the roots. If we are correct in our surmise, we can only suggest that the reason of the root failure is due to one or other of the following causes: Too dry or too wet at the root; a too heavy application of artificial or some other manure; or that the vines have been carrying too heavy crops in previous years. In any case the border should be examined and the condition of the roots ascertained; it will be found most probably that new soil should be added and the drainage made perfect.

**Exhibiting Grapes** (W. B.)—The double bunch of Alicante Grapes having two separate and distinct stems attached to the lateral is not eligible for exhibition as a single bunch, and would certainly be disqualified by competent judges.

**Salvia virgata** (ROSE DOWLING).—The plant noticed in the mixed border as Kew flowering in July last is Salvia virgata. It is an European plant, and grows about 2½ feet high. It is of a sub-shrubby character, the branches keeping green for a great portion of the winter, living through the year in places where severe frost is not experienced. The main branches are sturdy, and are produced fairly thickly from the rootstock, side branches are numerous, and on them are borne wrinkled, serrated, sage-like leaves 2 inches to 3 inches long. The inflorescences are in the form of long, upright, terminal racemes, the flowers being very numerous and purplish in colour. The flowering period extends over several months, and for eight or ten weeks in July and August it forms one of the most showy subjects in the herbaceous border. Its exceptionally good habit and free-flowering qualities, combined with the fact that it is an easy plant to cultivate if given good garden soil, warrants its being in every herbaceous border. It can be obtained from any one of the many nurserymen who make a speciality of herbaceous plants.

**Iris stylosa seed** (F. H. C.)—The seed of this pretty winter-flowering Iris may be sown any time between this and next February. The soil to use is very sandy loam, or loam with fine peat to about one-third will do quite well. Make the whole very sandy, pass through a fine sieve, and use the rough screenings of the soil above the ordinary drainage. Pans or pots will be best, by reason of uncertain germination, but if you employ a box instead let it be a somewhat substantial one, and char the inner surface before using it, or if you have a large quantity you may sow in a frame in prepared soil. In any case make the soil below the seed-sowing level quite firm and level. Sow on this surface a layer of sand—silver sand for preference—and then scatter the seeds thinly over the surface. Finally, cover with about three-eighths of an inch of fine soil, making it moderately firm. If you wish to quicken germination some portion of the whole may have the benefit of greenhouse treatment; but the warmth given must be slight, and particularly so when the seedlings appear. The ultimate flowering of the seedlings depends entirely on the treatment hereafter, and you cannot do better as the seedlings attain sufficient size than to prick them off into boxes or a frame set apart, with a similar soil to that already noted. With twelve months in such a frame, permanent quarters should be selected and prepared, when the flowering of the most forward should follow in a year or perhaps two years at most.—E. J.

**Roses for arches and pillars** (BELEBROUGHTON).—Your selection of Roses for the above purposes is a very good one if you transpose one or two. For instance, the Dawson Rose, Alister Stella Gray, and Ards Rover would be more suitable as pillars, replacing them for the arches with the more vigorous kinds, Euphrusyne, Noelle Nabonnand, and Waltham Climber No. 1. Your idea of alternating a summer blooming kind with an autumnal is a commendable one. We should certainly prefer the lovely Felicité Perpétue to Paul's Single White, but as this latter is a good autumnal you probably chose it for this reason, although you place it next to another autumnal, Waltham Climber No. 1. We also think you would prefer Queen Alexandra to Psyche, and Electra would be better than The Garland. Mme. Jules Siegfried is one of the overlooked Roses, and is worthy of a place in the smallest collection. Dorothy Perkins and The Garland being practically both summer bloomers, you could well replace the latter with Mme. Jules Siegfried, and thus maintain your arrangement of alternate summer and autumn bloomers. Germaine Trochon is another beautiful kind, but we do not see where you could improve your list by adding it. We should, however, advise you to grow it in bush form, only that when pruning retain its growths from 1½ feet to 2 feet in length.

**Rockery border** (TEMPUS FUGIT).—We consider you have acted for the best in changing the site for the above, as from your description the former one did not appeal to us in the least. In all these matters so much turns not exactly on the soil but upon the material at disposal and the inclination to make it what it should be above all things—a place where plants may be grown. We quite follow you in the lower sketch you give, and if you can carry this out in detail there is every hope of seeing the border clothed with plants. The dry wall should be very helpful, and by working some soil into the crevices it will be possible to beautify it also with plants. If in the end you cannot command much shade for the plants you have the consolation that a rigid selection of sun-loving plants is possible, and for your very sandy soil even desirable. As you appear now, judging by the sketch, to possess a better position this will be more readily convertible into a presentable whole. The thing to avoid, as the soil is so sandy and the drainage therefore excessive, is throwing the mounds of soil too high, and likewise rendering the sloping sides too acute. This you appear to have provided for in the gentler slopes of the lower sketch. If you follow this out, make a miniature rugged pathway in the upper part for convenience as well as utility. Here, as the crown is reached, a larger space on the right of the ascent may be treated as a bed for grouping, say *Cistus ladaniferus*, for example. It may be necessary to support the front side of this bed with stones, the crevices of which may be laid with soil and planted with *Campanula muralis*, *Corydalis lutea*, or *Achillea umbellata*, all of which have a drooping tendency. If you follow what we suggest in this you have the key to our views in the treatment of the whole, for in the same way, if modified in degree and detail, it will be easy to plant all side walls and sloping pathways with suitable plants. As to the sandy pathways we would not hesitate to let the soil act for the pathway, but if you have a large amount of stone on hand there is no reason why some may not be used, indeed many would prefer it. If you use stone, however, it will be well to place it that plants may jut out here and there, or proceed from below them or beneath. In this way many *Saxifragas* could be used, also *Campanula pumila*, *C. Erinus*, Thrift, and such like, the object being to cover and furnish the bank with living plants. In the larger mounds, where the chief features will be placed, you must provide a good depth of soil for the plants, and firm planting is necessary.

**Seakale blanching** (S. C. G.)—We gather from the description you give of your Seakale that the plants are old, and many sent up flowers which were later cut off. When that is the case it is seldom that crowns fit to produce blanching heads in the winter are formed. In the case of Seakale permanently planted, when the heads have been blanched in the early spring by excluding the light and have been cut, the root-stems should then be cut close off level with the ground. They will then form new crowns, and if these be thinned down to one or two at the most none will bolt off to flower. In that way stout crowns are formed and sound when in the late autumn the leaves fall. Then these crowns can be covered up with

Seakale pots, large plant pots, or drain-pipes, and be also thickly covered with long manure or tree leaves to exclude light and air, or else with mounds of fine coal ashes and some soil over them. In that way good blanched Seakale is obtained in the early spring.

**Irises** (R. D.)—There is not the least need to dig in ground for any of the Flag Irises. We imagine the absence of flowers to be due to the time and method of replanting, and that the plants having now re-established themselves and made new rhizomes will flower quite well in May and June, 1902. Lime is a good corrective in the event of soil being over rich in humus, but in the case of freshly planted subjects it is another matter. These Irises appreciate a rich soil, and it is possible the plants were not over large when planted. Had they been twice the time without flowering we would think something was wrong, but having been planted "about fifteen months" infers that the border was planted in July,

1901, not a good time certainly in a year of such prolonged drought. In these circumstances the season's growth would be almost lost to the plants, and if prior to the planting the old clumps had become weakened we can readily understand that some time must elapse for complete recovery. We imagine the strong growth is but the natural outcome of

November. Whenever you plant have the ground ready when you order from the nurseryman. Then, as soon as the trees or bushes come to hand, open holes, never deep, and plant as quickly as you can. If the roots have dried in transit, soak them for an hour in a pond or tub of water before planting. In the case of Raspberry canes or suckers plant only those which are well rooted. Do not shorten the canes now; leave that till March, then cut back to within 6 inches of the ground. To secure good permanent plants it is absolutely needful that the first-planted canes and fruit crop be sacrificed.

**Raising seedling Potatoes** (M. S. B.)—As it is now a recognised fact that Potato varieties do in time become weakened in constitution, probably because necessarily propagated annually by means of tubers, it does seem as if the raising of new varieties from seed was indispensable to the perpetuation of our Potato crops. That there are varieties which have endured for fully fifty years there can be no doubt, and some, such as the Ashleaf Kidney, much longer. Yet it does seem as if the great main crops on which we so much depend for our chief supplies were of necessity the sooner exhausted because so marvellously productive in early years. In any case the raising of good cropping or even of first early good eating varieties still finds ample appreciation. But your hopes for success in this direction must materially depend on the knowledge as to procedure you may possess and the varieties you may have at disposal for such purpose. You should obtain tubers of at least from twelve to twenty so as to have ample variety to work upon, as all may not flower, or if they do, not quite simultaneously. And even then it does not always follow that if they flower you obtain pollen. The greater the tuber crop a plant produces, the less will be its pollen. To get over that difficulty the best plan is to put a few tubers of each variety into 8-inch pots singly, so as to partially starve them. That tends to check tuber production and to increase pollen production. It may be wiser to have the plants tied up to stakes and kept under glass, but they should have ample light and air; otherwise stand them outdoors in a sunny place. When any variety is selected as seed parent remove all flowers but two, and from these carefully remove in an early stage of development the pollen cases, then gather several flowers from the intended pollen variety with the point of a penknife, cause the pollen to fall out on to a sheet of white paper, pick it up with a camel's hair brush, and touch the points of the pistils on the seed flowers and cross-pollination is complete. In any case get the proper varieties first.

**Plants for Dublin** (H. D. R.)—*Plaut Romaena*, *Citrus trifoliata*, and *Eucryphia* on south wall; the evergreens and others would succeed with you on open border. Eastern aspects on walls are bad for evergreen shrubs, as the sun shines too suddenly upon them after frost. You should obtain local advice as to planting.

**Grapes shrivelling** (E. C.)—Without knowing something about the health of the Vines and the conditions under which they are grown it is difficult to give a trustworthy or helpful answer to your question. The cause of shrivelling sometimes is due to the imperfect fertilisation of the flowers, scorching through inadequate ventilation, and dryness at the root, the latter being the most common cause.

**Hollyhock diseased** (B. LEVETT).—The Hollyhock leaves you sent are undoubtedly attacked by the Hollyhock rust (*Puccinia malvacearum*). Your plants may have been grown from infected seed, as the seed from carpels which have been infected produces diseased seedlings. If you collect and burn all the leaves as they fall your plants should not be attacked next year, but if they are, on the very first appearance of the disease—and you should be on the lookout for it—spray three or four times, with an interval of a week between each spraying, with Bordeaux mixture.—G. S. S.

**Seedling Hippeastrums** (H. W.)—We can scarcely understand your seedling Hippeastrums showing their flower scapes now, unless they are hybrids, in production of which *H. reticulatum* or *H. aulicum* has played a part, as these two species and their hybrids bloom in the autumn or early winter. As far as we can judge by your letter the treatment does not appear to be at fault. We do not think that you can safely rest those that are now showing their flower scapes till January, as the blooms would in all probability go blind, but as you cannot command much heat the better way will be to give them but little water and allow them to come on gradually. In this way you will most likely find some time elapse before the flowers expand.

#### TRADE NOTE.

ROYAL APPOINTMENT.

MESSRS. WILLIAM BULL AND SONS, new plant, seed, and bulb merchants, 536, King's Road, Chelsea, London, S.W., have been honoured with the appointment of florists to His Majesty the King.

#### CATALOGUES RECEIVED.

*Fruit Trees and Plants*.—Messrs. H. Cannell and Sons, Swanley, Kent.

*Bulbs*, &c.—Messrs. C. R. Shilling, Winchfield, Hants. *Carnations, Picotees, and Auriculas*.—Mr. James Douglas, Edenside, Great Bookham, Surrey; Messrs. Blackmore and Langdon, Tiverton Hill Nursery, Bath.

*Alpine Plants, Hardy Ferns and Orchids*, &c.—Jardins Correvon, "Floraire," Chene-Bourg (Geneva).

*New Hybrid Alpine Iris*.—Mr. W. J. Caparne, Rohais, Guernsey.

*American Seeds*.—Messrs. J. M. Thorburn and Co., 36, Cortlandt Street, New York.

*Plants*.—M. V. Lemoine et fils, Rue du Montet, Nancy, France.

No. 1616.—VOL. LXII.]

[NOVEMBER 8, 1902.

## THE CHRYSANTHEMUM.

**A**S the Rose is queen of summer flowers, so the Chrysanthemum holds undisputed sway during the late autumn and early winter months.

It may be gathered out of doors perhaps later than any other of our border flowers, and when sharp frosts disfigure and destroy its beauty there, one can, with the protection of a greenhouse that is capable of keeping the thermometer some few degrees above freezing point, still enjoy such charming variety of floral beauty as the Chrysanthemum alone at this season can supply. When one sees such a display of Chrysanthemums as that brought together at the National Chrysanthemum Society's exhibition held in the Royal Aquarium on Tuesday, Wednesday, and Thursday last, one is able to realise how vast and rapid has been the improvement effected in the Chrysanthemum during the past few years by workers both at home and abroad, and what a wealth of material the enthusiast and would-be cultivator of this grand autumn flower has to choose from. If particulars of the origin of the varieties of Chrysanthemums shown at this exhibition were available, with whom, we wonder, would rest the honour of being at the top of the poll? We fear that English growers could not rightly claim the privilege; it is probable that the creations of French, American, and Australian raisers would take precedence both in point of numbers and individual beauty.

If, however, we acknowledge that we have yet something to learn from the Continent, the Colonies, and America, with respect to the raising of new varieties, we yield to none in the matter of cultivation. It is safe to say, we think, that nowhere else could such a wonderful exhibition of the Chrysanthemum grower's skill be seen as at the Metropolitan display above referred to. Yet gorgeous as are the colours of the massive and handsome Japanese blooms, varying so astonishingly in form of flower and shape and disposition of petal as almost to make one wonder what a Japanese Chrysanthemum really is, neat and correct with every petal in place as are the incurved flowers, we were much disappointed to find that at this national exhibition of Chrysanthemums, those free-flowering decorative sorts that provide one with a profusion of flowers at a slight cost were so sparsely represented as to require much seeking ere they could be found.

Yet to the amateur enthusiast, who must ever remain by far the largest grower of this, as of every flower, no other section of Chrysanthemums appeals to nearly such an extent. But comparatively few growers can hope to achieve such success as that evidenced by the magnificent blooms shown at the Aquarium. It was refreshing to see the single varieties better represented than usual, and there appears to us to be no reason why they and the other types most generally useful should not be earnestly encouraged.

Why should we not be able to speak of "garden Chrysanthemums" as we do of garden Roses; the beautiful and comparatively recent additions to the latter have revolutionised Rose gardens. The Chrysanthemum is equally as valuable in its sphere as is the Rose, and the possibilities of selection and hybridisation with the idea of producing Chrysanthemums for the garden are unbounded. Early-flowering varieties have been greatly enriched during the past few years by the addition of good novelties, and it is to be hoped that before long we may be able to say the same of late Chrysanthemums. At present, good late varieties are scarce and badly wanted. They are wanted to fill the void which exists in the gardens of most amateurs for some weeks before spring flowers are to be had. Not everyone has either the opportunity or the accommodation for forcing plants to bloom out of their natural season, and to such persons, and they must surely represent the great majority of plant lovers, new and improved late Chrysanthemums would be most heartily welcome.

The National Chrysanthemum Society has, we presume, held its last exhibition in the Royal Aquarium. It is now homeless, and has lost a good friend in the manager of this London theatre of varieties, who, by substantial money awards and in many other ways, even in the face of at one time strong competition, has helped the society and prevented this three day Chrysanthemum feast, held midst the turmoil of shouts and music of a big organ, from migrating elsewhere.

It remains to be seen whether the society, which may be regarded as a pioneer in all things concerning the exhibition Chrysanthemum, will continue to stand firm without the attractions of a variety show, which are an inducement to many living in the country to spend a few days in the Metropolis for the purpose of sight-seeing and meeting friends. We venture to think the National Chrysanthemum

Society will need vigorous management to preserve its influence unless some bright central hall can be discovered, and the funds continue to receive such assistance as the manager of the Royal Aquarium has given ungrudgingly in the past.

The society has had a long and honourable though somewhat chequered career, and we heartily wish it success in its efforts to secure a new home till the Horticultural Hall is an accomplished fact, when we presume its exhibitions, in common with those of all floral societies which have their headquarters in the Metropolis, will be held under the roof of that building.

## KEW NOTES.

### INTERESTING PLANTS IN FLOWER. Temperate House.

ACACIA FRAGRANS, A. linifolia, Cestrum aurantium, Chrysanthemum nipponicum, Daphne Dauphinii, Lavatera maritima var. bicolor, Leonotis dubia, Lonicera etrusca, Pitcairnia ferruginea, Tricorytis hirta, and Veronica speciosa (several varieties).

### Palm House.

Leea coccinea, Medinilla javanensis, and Sterculia mexicana.

### Orchid Houses.

Acinia Barkeri, Angraecum arcuatum, A. vesicatum, Bulbophyllum dayanum, B. recurvum, Calanthe Veitchii, C. vestita var. rubro-oculata, Cattleya bowringiana, C. bowringiana var. violacea, C. labiata, Cirrhopetalum Hookeri, Cochlioda vulcanica var. grandiflora, Cœlogyne fuliginosa, C. massangeana, C. praecox var. wallichiana, Compacta macroplectron, Cymbidium gammieanum, C. traceyanum, Cypripedium Charlesworthii, C. harrisanum, C. insigne and var. Sanderae, Dendrobium bigibbum, Epidendrum Armstrongii, E. equitanus, E. euvectum, E. nocturnum, E. vesicatum, Eria barbata, Eulophia pulchra, Grobya galeata, Lælia autumnalis var. atrocubens, L. Perrinii, Listrostachys (Angraecum) Monteirea, Lycaete Skinneri, Masdevallia macrura, M. reichenbachiana, M. veitchiana, Maxillaria crassifolia, M. grandiflora, Necbenothamia gracilis, Odontoglossum constrictum, O. Hallii, Oncidium bracteatum, O. cheirophorum, O. crispum, O. excavatum var. aurosum, O. variicosum, Pleurothallis pulchella, Polystachya leonensis, P. luteola, P. odorata, P. rhodoptera, P. rufinula, P. tessellata, Scaphosepalum ochthodes, Sophronitis cernua, Stanhopea oculata, and Vanda cœrulea.

### T Range.

Echmea fulgens var. discolor, Begonia (various species and varieties), Billbergia Moreli var. paucifolia, Caraguata lingulata, Clerodendron speciosum, C. splendens, Dædalanthus parvus, Erica conspicua, Hemanthus albillos, Hippeastrum vittatum, Justicia calycotricha, J. furcata, Klugia notoniana, Lindenbergia grandiflora, Nesembryanthemum blandum, Pentas carnea, Pinguecula caudata, Pitcairnia karwinskiana, P. Rœzlii, Ruellia amœna, Sonerila (several varieties)

Spathiphyllum Minabasse, Tetranema mexicana, and Tupistra nutans.

*Groinhouse.*

Among other things the following are very noticeable: Abutilons in variety, Begonia coccinea, B. echinosepala, Calceolaria Burbidgei, Chrysanthemums in variety, Plumbago capensis, Salvia azurea, S. splendens var. grandiflora, and Tecoma Smithii.

*Rock Garden and Herbaceous Ground.*

Aster cordifolius, A. diffusus, A. ericoides, A. horizontalis, A. tartaricus, A. Tradeantic, A. turbinellus, Baldwinia uniflora, Chrysogonum virginianum, Lobelia urens, Polygala Chamaebuxus var. rosea, and Primula japonica.

## OBITUARY.

### C. MARIES.

THROUGH the sudden demise of Mr. C. Maries, which occurred on October 11, at Gwalior (India), horticulture has lost one of its most energetic members, and one who, during the few years which were devoted by him to plant collecting, enriched the European collections with many plants of great value. He was in the employment of Messrs. James Veitch and Sons, when, in 1876, he was entrusted with a mission to explore part of China, Formosa, and Japan, with a view to introducing into Europe some representatives of the splendid vegetation which was known, or was only supposed to exist, in these countries, and especially in the great Ichang Valley. Mr. C. Maries succeeded in sending home and in good condition such plants as Platycodon grandiflorum Mariesii, Rodgersia podophylla, Abies Mariesii, Styrax Obassia, Pteris longifolia Mariesii, Hamamelis mollis, Hydrangea Hortensia Mariesii, and the charming H. Hortensia roses which deserves a much more extended cultivation than it receives at present. He also reintroduced the long-lost and very pretty Caryopteris Mastacanthus and a host of other plants of equal merit. His success in introducing these plants is all the more remarkable if we take into consideration the difficulties with which collectors had to contend in those days of comparatively slow navigation, and was mainly due to the care, and, I may add, also the ingenuity he displayed in the packing and forwarding of these plants to which he was so devoted. Later he was appointed superintendent of the Gardens of Durhingah, and ultimately of the magnificent gardens of Gwalior, where he made some very extensive alterations and improvements during the many years that he had them under his direction.

That Mr. C. Maries had well employed his time, and that his exertions were well and duly appreciated, is evident from the fact that, besides being an occasional contributor to the gardening papers and to the Journal of the Royal Horticultural Society, he was also a fellow of the Linnean Society, and was one of the recipients of a Victoria Medal of Honour. To his widow, his son, and his daughter we offer our deepest sympathy.

### JOHN BAXTER.

THE death is announced of Mr. John Baxter, who retired exactly two years ago from the service of Colonel McCall, Daldowie, where he had been gardener during the previous forty-one years, and since his retirement had resided at Uddington, near Glasgow. For many years Mr. Baxter had been intimately associated with Violas as a raiser of the best varieties, and also as a chief exponent of their cultivation. Though latterly Violas had been his favourites, other florists' flowers, such as Dahlias and Hollyhocks, had received much of his attention from about the year 1860 onwards. As a young gardener his time was passed in the famous Keir Gardens, near Stirling, and the Edinburgh

THE LATE MR. JOHN BAXTER.

Botanic Gardens, under McNab, then to the Earl of Kintore's, passing thence to Daldowie at the early age of twenty-three. The late Mr. Baxter had reached the age of sixty-six at the time of his death. An account of Mr. Baxter's career and life work appeared in THE GARDEN, December 8, 1900.

### MY GARDEN PATH.

THOU say'st, "Not ugly is the garden of thy choice, Yet thou in solitude appearest to rejoice; The pathway is so narrow, there is no room for two. To wander side by side, in converse sweet and true."

In solitude? Oh, no! There's ample room, I think, When friends together walk, and arm in arm doth link; Oft have I wandered so—and never yet alone—The dear one by my side, my arm around her thrown.

Before us or behind a little child can play, And sometimes in between us gently make its way; While, if on either side we chance the hedge to touch, 'Tis but the fragrant Roses who in play our shoulders clutch. The pathway thus for me quite broad enough has been—The only road to joy that I have ever seen.

For formal visitors alone it is not amply wide, And I with such should never wish to wander side by side.

E. M. M.  
—(From Rückert's "Weisheit des Brahmanen.")

### THE EDITOR'S TABLE.

#### VIOLET PRINCESS OF WALES.

From Mr. Osmond G. Orpen, Hillside, West Bergholt, Colchester, we receive a delightful gathering of Princess of Wales Violets grown quite in the open. The flowers are large, most deliciously scented, and a splendid dark violet colour. The footstalks are quite 12 inches long, and the leaves remarkably vigorous. No one who once has seen this Violet, now generally recognised as the finest of all, will care to be without it. Such charming flowers from the open in October are very welcome.

#### A SEEDLING ASTER.

Mr. A. R. Upton, the Guildford Hardy Plant Nursery, Millmead, Guildford, in sending a

seedling Michaelmas Daisy, writes: "The Aster which I am sending you is a seedling from my Compton Heath Nursery, and is now in full bloom. It is about 3 feet high, and a strong grower. So far as I know it is quite a new variety, and such a good colour so late in the year should be valuable. I should be interested to hear your opinion."

[The flowers sent are certainly of a very good distinct colour, quite a pretty blue-purple, and they are very freely produced.]

### AUTUMN FLOWERS.

Mr. James Page, Knole Gardens, Salisbury, writes: "I am sending you a few flowers cut from outside borders, showing the mildness of the season. Lobelia cardinalis, Montbretias, Dahlias, Marguerites, Roses, &c., are all looking well. The Rose is Mme. Isaac Periere, both standards and bushes are full of good bloom; in fact, quite equal in colour, form, and scent—if not better—than we get them in June. One standard at the present time is carrying eighteen flowers expanded and expanding and thirty-two buds just opening. I think it is one of the best autumn-flowering Roses. I can cut—not one or two, but scores two or three times a week. It does especially well here both as a standard and bush on its own roots."

[A delightful gathering of autumn flowers.]

### DIPLADENIAS.

Mr. J. Glasheen, The Retreat, Cam, Gloucestershire, sends a few blooms of Dipladenias in several lovely colours. These are amongst the most beautiful of stove flowering plants, and no one with a house sufficiently well heated should be without them. Mr. Glasheen says: "It is surprising when one considers their rich colours and their long flowering period that Dipladenias are not more popular. In combination with Allamandas, Gloriosas, Schubertia, &c., they have made a brilliant display on the roof of the stove house here since the beginning of July."

### ASTER "THE GARDEN."

Mr. Amos Perry, Hardy Plant Farm, Winchmore Hill, N., sends us a gathering of Michaelmas Daisies in many beautiful sorts. They are striking testimony to the value of Michaelmas Daisies as autumn flowers. Mr. Perry says that owing to the cold nights the flowers are not so good as they would otherwise have been. That named in compliment to THE GARDEN is a new one, distinct from any other by its remarkable pyramidal habit, the spikes of flowers measuring fully 3 feet in height, the whole plant growing about 5 feet high. The long slender side shoots will render this variety very useful for cutting, and the colour, a good deep purple-blue, is very pleasing.

### NOVEMBER FLOWERS FROM WORCESTERSHIRE.

Mr. Arthur R. Goodwin, The Elms, Kidderminster, kindly sends a gathering of autumn flowers, picked on November 3 from the open garden. They comprise Gentiana acaulis, Saxifraga Fortunei, Erodium pelargonifolium, Gypsophila Rokejeka, with pale pink flowers, and Chrysanthemums George Wernig and Mme. la Comtesse Fouche de Cariel. Mr. Goodwin says "the first-named Chrysanthemum is very late this year. The latter is almost the most beautiful outdoor variety I know, habit, foliage, and flowers being perfect. The Saxifrage always does well in a fine autumn, and is grown here on a north rockwork in shade."

[The Chrysanthemum Mr. Goodwin speaks so highly of is a splendid colour, a rich bronze buff, and shows well what delightful plants these free-flowering Chrysanthemums are. No one should be without them, for together with Michaelmas Daisies they are responsible for much of the autumn beauty of gardens.]

## NOTES OF THE WEEK.

## FORTHCOMING EVENTS.

## CHRYSANTHEMUM SHOWS.

November 8.—Leicester and Highbury (two days), and Hayes.

November 10.—National Chrysanthemum Society's floral committee meet.

November 11.—Birmingham (three days); Brighton and Sussex (two days); Dulwich (three days); and Oxford.

November 12.—Hull, Brighton and Hove, Folkestone, Sutton, Ipswich, Chester Paxton (two days), York (three days), Winchester, Wandsworth, Banbury, and Buxton.

November 13.—Alsager, Bournemouth, Bristol, Chesterfield, Epsom, King's Lynn, Lewes, Lowestoft, Melton Mowbray, Sittingbourne, Swansea, Tonbridge, Wimbledon, and Wisbech (each two days).

November 14.—Bradford, Stockport, Sheffield, Barnsley, Devon and Exeter, Walthamstow, Tottenham, and Pendleton and District (each two days).

**"Notes on Lilies."**—The editor of the *Gardeners' Chronicle* writes: "With reference to Mr. Peter Barr's complaint under the above heading, on page 308 of THE GARDEN, November 1, please see the *Gardeners' Chronicle*, October 13, 1900, page 283, where the letter of which Mr. Barr writes appeared in full."

**Shade-loving perennial Aster.**

As most of the family do best in an open sunny situation it is rather curious to find that the old *Aster longifolius formosus* (renamed at the *Aster conference A. levigatus*) does best in shade. But so it is. I have repeatedly grown clumps in various positions, but find that those exposed do badly, the foliage growing brown and sparse, and the flowers few and badly formed. But those in shady parts do well and flower freely. These remarks apply equally to *A. vimineus*. A liking for shade is inherent also in *A. cordifolius*, though in a less degree. Still, plants in a north aspect both look and do better than elsewhere.—T. J. WEAVER, Thirlwood.

**A French Colonial School** has been established at Nantes by the French Government for the culture of economic plants useful to intending planters in the French colonies, and for giving them the necessary instructions regarding their culture. The management of this new school has been given to a young Frenchman, Mr. H. Navel, who was a student at the National Horticultural School at Versailles, also in the Royal Gardens, Kew, and the Jardin Colonial of Vincennes, under the direction of Mr. J. Dybowski. Besides having spent a good deal of his time in London nurseries, he also had the advantage of having during his stay in England filled the post of vice-president of the Société Française d'Horticulture de Londres, to which many of the English nurserymen and English gardeners having a knowledge of the French language belong. This institution is not only working for the benefit of young French gardeners living in this country, but it has also been the means of procuring good positions on the continent for the few English gardeners who have sought its support in that direction. Our best wishes to the new directeur, who informs us that he has a most pleasant recollection of his stay in England.

**Calceolaria Burbidgei.**—The parentage of this Calceolaria has puzzled me a good deal, hence I read the note from the raiser on page 281 of THE GARDEN with especial interest. Judging by the general appearance of the plant it has always seemed to me that the parents were *Calceolaria Pavonii* and *C. amplexicaulis*, and on this point I see the "Kew Hand List" agrees with me, for the following is recorded: *Calceolaria Burbidgei*, garden hybrid, *amplexicaulis* × *Pavonii*. Mr. Burbidge in the article in question gives *C. fuchsiaeifolia* as the seed-bearing parent, which increases the puzzle still more, and the following, taken from THE GARDEN of May 4, 1895, when a colored plate of this *Calceolaria* was given, does not serve to elucidate matters. Concerning the

parentage Mr. Burbidge at that time wrote: "The parent plants were *C. deflexa*, perhaps more generally known as *C. fuchsiaeifolia* in gardens. The male parent was the old *C. Pavonii*, named in honour of the traveller Pavon. The only element of doubt as to the above parentage is that a plant or two of the well-known *C. amplexicaulis* was in bloom in an adjacent greenhouse, and it is just possible some insect may have carried its pollen to the stigmas of *C. deflexa*, which I had only touched with pollen from *C. Pavonii*. Personally I should have had no suspicion of this having taken place, all the evidence of the hybrid plant itself bearing in a contrary direction; but when Dr. John Macfarlane was making his series of microscopic studies of the minute structure of various hybrid plants at Edinburgh some years ago I sent him *C. Burbidgei*, together with both its parents, and he then thought that he detected signs of *C. amplexicaulis* in the hybrid." At all events we are greatly indebted to Mr. Burbidge for raising such a beautiful winter-flowering plant, though its parentage may be *C. deflexa* × *C. Pavonii*. On this point I have my doubts, and that others are of the same opinion is shown by the "Kew Hand List."—W. T.

**Lachenalias.**—Reading Mr. H. T. Martin's remarks on Lachenalias, page 135 of THE GARDEN, August 23, I would suggest an addition to his list of names. Driving along the Hartebeest River, Caledon, Cape Colony, my eye was attracted by a patch of brilliant purple-red colour. I was soon out of the cart and up the bank, where, to my extreme delight, I found it was a Lachenalia I had never before seen in flower, figured or described, the spike of flower being about 6 inches long, and the height of plant about 9 inches. My pick was soon in the ground, and a good handful gathered and bagged as the prize of two days' work. On returning to Cape Town I was informed it was described in "Flora Capensis" under the name *L. rosea*. Anyone who has grown *L. pendula* must feel surprised Mr. Martin should omit it, as it is one of the most distinct of the family. I freely admit there are Lachenalias that would only be prized by collectors, such as *L. orchoides* and its many forms. Of whites, *L. contaminata*, *L. orthopetalala*, *L. pustulata*, with its blistered-like leaves, and *L. liliflora*; these are really pretty plants, and I recommend them for pot culture, five or more in a pot. *L. glauca* is very distinct, flowers tinged blue, leaves heavily spotted; *L. purpurea cerulea*, with blistered-like leaves and beautiful purple and blue flowers; *L. unifolia*, with its one leaf and blue-tipped white flowers, is both distinct and beautiful. I wish Mr. Moore of Glasnevin Botanic Gardens would seriously take up this entire family, and show the flower-loving public how much beauty and real intrinsic interest are lost in neglecting these plants. Our good friend the Rev. John Wilson did much to prevent the family from all but disappearing when he crossed *L. aurea* and *L. luteola* and raised a batch of seedlings with the free-flowering of the latter and the rich yellow of the former. It is curious that *L. luteola* is unknown at the Cape; I suppose, therefore, it must have been selected out of a batch of *L. tricolor*. It has not much claim to a place in the family, but its wonderful adaptation to culture in hanging baskets makes it valuable. At Stevens' auction rooms I once bought two large hanging baskets into which hundreds of bulbs had been planted, and the greenish yellow flowers literally covered the sides, bottom, and top of the baskets. All the Lachenalias I have yet met with were growing in good moist sandy loam, generally stony. Mr. Martin's remarks on watering just hit the mark and accord perfectly with the conditions that prevail when the Lachenalia is in flower at the Cape. Moist sandy loam, the bulbs just under the soil, but not exposed. As a rule, I found the plants with the base seldom more than 1 inch to 2 inches below the surface. *L. linifolia* grows in pure sand over moisture; I would therefore suggest it might be most successfully grown in pots, standing in saucers of water, resting on pebbles or broken crocks, so that air could get in as well as water and keep the sand sweet.—PETER BARR, V.M.H., Cape Town.

**Begonia Froebelii.**—When this Begonia was first introduced from Ecuador by Messrs. Froebel, nurserymen of Zurich, now about thirty years ago, autumn and winter-flowering forms were much fewer than they are now, hence this species, which would often flower well on into the autumn, was thought highly of, and for a few years at least was largely grown. Though this Begonia forms a tuber, it is not so solid as that produced by the ordinary tuberous-rooted varieties, but often consists of little more than a dense mass of fibrous roots, though sometimes there is a decided tuber. In this Begonia both the leaves and flowers spring direct from the root-stock, as the plant does not produce a stem after the manner of the ordinary tuberous-rooted forms. Another distinctive feature is that the leaves are thickly covered with hairs. The flowers of this Begonia are of a bright crimson or scarlet, individuals varying considerably in this respect. It has not been employed to any great extent by the hybridist: indeed, for some years after its introduction all attempts at hybridising, as far as I know, resulted in failure, but of late years it has, in conjunction with *B. polypetala*, given us a valuable hybrid form, *Begonia incomparabilis*, which Messrs. Veitch showed so well at the meeting of the Royal Horticultural Society on October 21. It is a bold-growing plant, with large leaves that often nearly hide the pot, and erect, many-flowered scapes of scarlet blossoms. This Begonia, which affords a delightful change from the Socotra hybrids, received an award of merit from the Royal Horticultural Society in November, 1895.

**Grafting Cianthus Dampieri.**—I was particularly interested in the note on grafting Cianthus Dampieri, page 307, as I have had several opportunities of seeing the plant in the Temperate house at Kew, which was alluded to in the above-named article. It was certainly a grand specimen, which showed well the suitability of *Colutea arborescens* as a stock for it. My interest in it was two-fold, as it is now about thirty-five years since the first grafted plant that ever came under my notice was grown in the south octagon of the same structure, but though it developed into a fine specimen, it was not, as far as my memory serves me, the equal of the recent one. The stock employed was *Swainsona gallegifolia*, now I believe known as *S. coronillifolia*. It was a vigorous seedling established in a small pot, and the scion was quite a young seedling of *C. Dampieri*. Two or three were at the same time grafted on *Cianthus paniculus*, but they did not succeed nearly so well as that on the *Swainsona*.—H. P.

**Sweet Violets.**—A pleasant surprise at the Kent Chrysanthemum show was a stand covered with vases, each containing a loose bunch of cut Violets with their leaves, shown, but not for competition, by Messrs. Isaac House and Son of Bristol. As the proverb says, "Everything comes to a good waiter," and since reading the article on "Sweet Violets, Old and New" in THE GARDEN, I hoped some day to see the variety Admiral Avellan, and here was a great bunch of it with large, almost claret-coloured flowers deliciously fragrant. In this interesting collection were two saints, both singles—St. Anne's Pink and St. Helena—being respectively pink and starch blue. The most striking, for the size of the flowers and long stalks, making them useful for bouquets, were Luxonne and La France. These were much alike, being of a real violet colour. There were all the old favourites, such as Marie Louise. I missed seeing the sweet-scented *Semperflorens*, which, I am told, blooms more or less all the year round, for someone had taken such a fancy to the bunch that they had stolen it.—WINIFRED SPURLING.

**Bright-coloured Chrysanthemums.**—The fact of its being "autumn sae pensive in yellow and gray" instinctively made me turn away from the cinnamon-coloured, buff, and other dingy-coloured Chrysanthemums and feast my eyes on the bright pink and yellow flowers at the Kent Chrysanthemum show. Amongst the most beautiful of the Japanese blooms I noticed were Mrs. G. Mileham and Lily Mountford, pale of a bright clear pink; Rayonette, with narrow pale pink petals; Miss Mildred Ware, shrimp-

coloured : Matthew Hodgson and H. Weeks, both good reds ; and the copper-coloured Pompon Abri de Noel. The yellow Chrysanthemums were all beautiful, the most noticeable being Mrs. Greenfield (golden-yellow Japanese) and Dorothy Gibson (bright yellow reflexed). The baskets of Chrysanthemums were decidedly sombre, those gaining first, second, and third prizes all containing dark red and bronzy yellow flowers ; perhaps the competitors were tied to these shades by rule, otherwise a basket filled with white and pink Chrysanthemums would have been much more effective.—WINIFRED SPURLING.

**Wood Anemones.**—The accompanying illustration is from a photograph taken in the woods near Bolton Abbey, Yorkshire, when the Wood Anemones (*A. nemorosa*) were in their full beauty. This charming little spring flower is one of the most beautiful of our wildlings, and it is to be regretted that it is not naturalised more extensively in our gardens. Intending planters should not delay, for now is the best time to commence.

**Pear Styrian.**—This Pear is not much grown in the South, but in the North and the Midlands it is a favourite variety. It is also

very large, flushed with red on the sunny side, and in season as soon as gathered from the trees in October and through November. It is equal to the Verulam or Black Worcester for stewing, but is earlier. Grown on the Quince stock in bush or pyramid form it is a profitable variety, not unlike Uvedale's St. Germain in appearance and size, but much sweeter.—A. C. N.

#### Port Elizabeth and East London.

At Port Elizabeth I saw the pink Freesia, but only two flowering bulbs of it. The lower part of one flower was stained orange-yellow, that of the other was clear white. On the veldt the yellow Freesia is abundant, but whether it is the one I sometimes see referred to in the gardening papers as *F. aurea* I cannot say ; but, described, your readers may know it. The upper part of the flower is lemon-yellow and the lower part rich orange-yellow. On my official visit I may learn more about the origin of the pink Freesia. The flowers are rather small, the colour is pleasing, and the fragrance rich. East London seems to be the home of *Cyrtanthus*, scarlet, white, and yellow. At one cottage door I saw a large pot full of the scarlet one, a lovely sight, and the same one in

of the varieties : Baldwin, Ribston Pippin, Golden Russet, Gravenstein, Fallawater, Emperor Alexander, North Star, Twenty-ounce Pippin, Gloria Mundi, Blenheim Pippin, King of Pippins, Ben Davies, Wealthy, and Northern Spy. To show the fine quality of the fruit King of Pippins weighed 15oz. ; Bietigheimer, 16oz. ; Fallawater, 14oz. ; and Ribstons varied from 7oz. to 12oz. each, these being only a few sorts taken haphazard. It may be mentioned that the above splendid samples were first exhibited at Kentville, King's County, Canada, and were sent by Sir Frederick Bowden and Mr. L. S. Eaton.—A. B.

**Nertera depressa.**—I have just been looking through the old volumes of THE GARDEN to see if there was any mention of the subject of this note being grown in the open. I find that about twelve years ago a correspondent wrote that he had never known it survive the winter in the open, and that at earlier dates two writers asserted that it could be grown in the open, but apparently did not speak from experience. I was interested because I now have a plant which has been in the open for more than twelve months covered with orange-red berries, a very pretty sight at this season of the year. It is growing on a ledge in front of an upright rock, where it gets but little sun, and has *Shortia galacifolia* on one side and *Oursinia coccinea* on the other. Its tiny light green leaves, rising not more than half an inch from the ground level, are thickly studded with the bright berries, which almost hide the foliage. The flowers are very inconspicuous, being pale green in colour and borne in the axils of the leaves. The berries began to colour in July, and show no signs of falling as yet. I was very doubtful as to its proving hardy, as it is a native of New Zealand, and before it had time to get established the winter was upon us with severe November frosts, a most unusual occurrence in this part of England. However, after looking rather unhappy through the winter it soon picked up when the spring came, and is now spreading freely. It is a charming little plant, that at this season of the year would well repay anyone living in a warm district who planted it in a sheltered nook in the rock garden. It is growing in peat, leaf-mould and sand.—S. W. F., S. Devon.

**Arctotis grandis.**—I quite agree with "R. D." in his estimate of this plant. It is a rampant grower, but its flowers, though individually pretty when expanded, are not borne with sufficient

freedom to render it a decorative subject in the garden. The branches are also very liable to be snapped off by high winds unless each one is tied to a separate stick, which still further detracts from the plant's appearance. For garden adornment it cannot compare with *Dimorphotheca Ecklonis*, whose flowers are very similar in colour, the petals being white and the centres purple, though these also have the disadvantage of only expanding in the sunlight. On a sunny day, however, a good bush of this plant bearing a couple of hundred or so expanded blossoms is a striking sight. I never allow the *Dimorphotheca* to remain in the border through the winter, but lift and pot, placing it under a verandah, or during sharp frosts in a cold house, but think it might very possibly survive if left out in a southern, wall-backed border. *Arctotis arborescens* I have always lost in the winter, but this year I have two specimens planted in broken stones and grit at the back of a retaining wall over which they hang, and shall be curious to see if their position and the poverty of their rooting medium renders them more hardy. In the Isles of Scilly they form immense bushes, and pass through the winter unharmed.—S. W. F.

WOOD ANEMONES IN THE BOLTON ABBEY WOODS.

known as Keele Hall Beurre, and Mr. Barron in his excellent list of Pears at the great conference of the Royal Horticultural Society describes it as sweet but not rich. Dr. Hogg says it is a most delicious Pear, and I have had it from walls grown on the Scottish border quite equal to Dr. Hogg's description. Few Pears are handsomer : the skin is smooth, clear yellow in colour, with bright crimson on the sunny side ; it is one of the most striking fruits I have seen. It does not keep long, in the North its season is October, and it is remarkably prolific. On a wall either south, east, or west it colours well. As a market fruit at the season named, as regards crop and value, it is one of the best, and on that account I have sent this note.—A. C. N.

**Stewing Pear King Edward.**—This is not a new Pear, as some might imagine from its name, and though I do not know its origin it is much more grown in the North than in the South. In the North it is prolific, and its large size is a point of importance. I am unable to go so far as some of my neighbours in the North, who advise its culture for dessert, as the flesh is dry and mealy, but for stewing it is excellent. The fruit

pockets around a pond near enough for the roots to reach the water. Mr. Wormald remarked : "I cannot understand why the people at home do not make more of this bulb, as the summers of England are warmer than the summers in East London." I fancy this may be accounted for by not putting a sufficient number of bulbs in a pot. There does not appear to be any difficulty in their cultivation here. On my return to East London, when visiting the eastern portion of Cape Colony, I may learn more on this subject. On the veldt I often met with *Cyrtanthus obliquus*, but not in flower.—PETER BARR, V.M.H., Durban, Natal.

**Canadian fruit in Liverpool.**—Accustomed as we in Liverpool are to seeing the best of imported fruit, the splendid exhibit of twenty-five varieties of Apples from Canada, which have been entrusted to the care of Sir Alfred L. Jones, must astonish even the most sanguine as to what we may yet expect from Canada. The Apples are brilliantly coloured, large, and of great solidity, and Mr. T. Dowd of Moorfields has arranged them in baskets and displayed them to the best advantage, to the great pleasure and interest of thousands of passers-by. The following are some

**Apricot St. Ambrose.**—I find the above Apricot to be a very good variety. I mentioned it in your columns some years ago, but I do not think there is harm in doing so again. It is a good grower, and while not actually free from that bane of Apricot culture, branch paralysis, it is less subject to it than any other variety I have. If not too heavily cropped its fruits finish of a good size and colour.—H. J. C., Grimston.

**Eustoma russellianum**, or *Lisianthus russellianus*, better known under the latter name, was exhibited at the Erfurt show last September in the best possible condition, and flowering well, by M. Ernst Benary of Erfurt. The plants excited great curiosity, as they are not much known outside botanical gardens. Perhaps until now they have always been kept too warm. Low propagating houses with plenty of light and a cool temperature will grow them well, the difficulty being to keep them free from the attacks of insect pests.—F. L., Dresden.

**Blue Hydrangeas.**—There is more than one means of giving the *Hydrangea Otaksa* the oft-desired colour of tender blue. Professor Molisch of Prague was the first to give it a scientific trial, and found the chief factor in all colouring compositions to be sulphate of aluminium, but this not being accessible to everyone common alum will do as well. It should be given in the quantity of a third of an ounce to a plant in a 7-inch pot. Somewhat more primitive is the manner of mixing the potting compost with the filings of iron, 1oz. per pot. The Dresden gardeners very often mix the compost with some old peat saved when repotting Azaleas; this answers very well, owing perhaps to a certain amount of oxide of iron and alum in the soil.—F. LEDIEN, Dresden.

**New crimson-flowered Japanese Chrysanthemum.**—We are not in the least overdone with Japanese blooms of a crimson colour, though several novelties gained distinction last season which possessed this and allied colours. Mr. Godfrey gave us many excellent new kinds, in which the warmer shades of colour predominated, and this season he has exhibited a very rich and deep crimson flower by the name of Exmouth Rival. At a recent meeting of the National Chrysanthemum Society's floral committee this richly coloured Japanese bloom was commended for its colour, and it certainly well deserved that distinction. It is a pity that so many of the crimson coloured sorts lack the size that all exhibition blooms are expected now to possess, and yet this want of size should not spoil their chance of gaining distinction. judiciously disposed on an exhibition show-board these somewhat smaller sized blooms are always useful for creating brightness and good effect in the stands, and they are not so much smaller than the others after all. Another crimson of considerable promise has also failed to gain a much hoped-for award. This is an English-raised seedling, and a flower of good form and capital substance. There is room in an exhibitor's collection for both these, and those who feel an interest in them may safely anticipate the production of good blooms of high quality another season. Except for the reverse of the florets the two varieties above mentioned may be regarded as good crimson selves, although one shade of crimson is quite distinct from the other.—D. B. CRANE.

**Schizostylis coccinea.**—This South African Iris was introduced nearly forty years ago, but for some time after that it was comparatively unknown in gardens. Within the last twenty years, however, it has made great headway in popular favour, and deservedly so, for its showy blossoms are borne at a time when they are particularly appreciated, viz., when summer-flowering subjects are on the wane. In the extreme South of England it must be regarded as thoroughly hardy, and even in the neighbourhood of London it will stand most winters out of doors, but is greatly benefited by being planted in a warm, well-drained border near a hot house; indeed, under such conditions as suit the Belladonna Lily. As this *Schizostylis* does not flower till autumn, when the weather is often too cold

and wet to allow the flowers to expand properly, it is in most parts of the country more appreciated for flowering under glass, where its bright blossoms make a welcome bit of colour at this season. By some the plants employed for this purpose are planted out during the summer, lifted in early autumn, and potted, while by others they are grown altogether in pots. Whichever course is followed they are greatly benefited by occasional waterings with liquid manure during the growing season. Neat little clumps in pots 5 inches or 6 inches in diameter associate well with the earliest-flowered Roman Hyacinths. In a cut state the spikes of this *Schizostylis* will remain fresh for a week or so.—T.

**Hybrid Lobelias.**—Those beautiful hybrid Lobelias, obtained principally by the inter-crossing of *L. cardinalis* and *L. siphilitica*, are by no means creations of yesterday, for about twenty years ago Mr. Smith, of Newry, raised many delightful forms, and among some notes taken in the summer or early autumn of 1885 in the nursery of Messrs. Backhouse, of York, reference is made to the great beauty of the hybrid Lobelias there, the following varieties being especially noticed: Amethyst, purplish blue; Challenger, rosy purple; Nizza, beautiful crimson-purple; Queen of Whites, white; Stromboli, purplish magenta; and Sunrise, cerise-scarlet. Of these the variety Nizza is, I see, still catalogued by Mr. Cannell. The spikes referred to by Mr. Campbell as having been shown at the Drill Hall on September 23 were simply superb.—H. P.

**Crinium augustum.**—With reference to the note about this beautiful stove bulbous plant (page 259), I may say that Mr. T. Carling, Dove Park Gardens, Woolton, Liverpool, has a plant now in bloom, and possibly the following particulars may be interesting: Height of stem from pot to base of leaves, 20 inches; length of foliage, 5 feet 3 inches; flower-scape, 3 feet 4 inches high; flower-tube, 7 inches long; number of flowers on spike, 29. The bulb is now in a 12-inch pot, having been repotted only once in twelve years, and that five years ago. No special treatment is given, yet it sends up a magnificent spike about three times each year, which sometimes bears more than thirty flowers. As you see by the flower sent, this *Crinum* is worthy of more general culture. The flower is imposing, and its perfume very powerful. Mr. Carling would be glad of information as to its propagation, never having succeeded in seedling it, nor is there the slightest sign of any offshoots.—R. G. WATERMAN.

**Rudbeckia fulgida.**—How charming for the gardener in autumn is this Cone-flower, yet how seldom is it seen and rarely mentioned in catalogues although introduced so long ago as 1760. Single stemmed plants, which are the best, quickly make dense bushes 3 feet through and 5 feet high. The small golden yellow flowers with an intense black shining disc are produced during the month of October in quantity, and brighten the garden when many of the summer occupants are past their best. The leaves and stems are slightly hairy.—E. M.

**Rudbeckia nitida.**—At the present time no plant in the herbaceous border is making a brighter display than this; growing fully 6 feet high it is quite smothered with its rich yellow flowers with green-brown discs; the latter are quite an inch high. The petals, of fully developed blooms, are thirteen in number, quite three-quarters of an inch wide, some a trifle more. For comparison I have grown *R. californica* and *R. Autumn Glory*, but find they are substantially the same. I cannot see the slightest distinction in either. *R. laevigata*, too, I have compared with the subject of this note and fail to find the slightest difference.—E. M.

**Carex scaposa.**—Of the 500 or so different species of Carex, comparatively few can be regarded as particularly ornamental, and of this small number the majority are considered only from a foliage point of view. One species, however, *Carex baccans*, which requires the temperature of a stove, is very attractive with its bright red seeds, which retain their position some time before they fall. With regard to *Carex scaposa*—the species under notice—it is

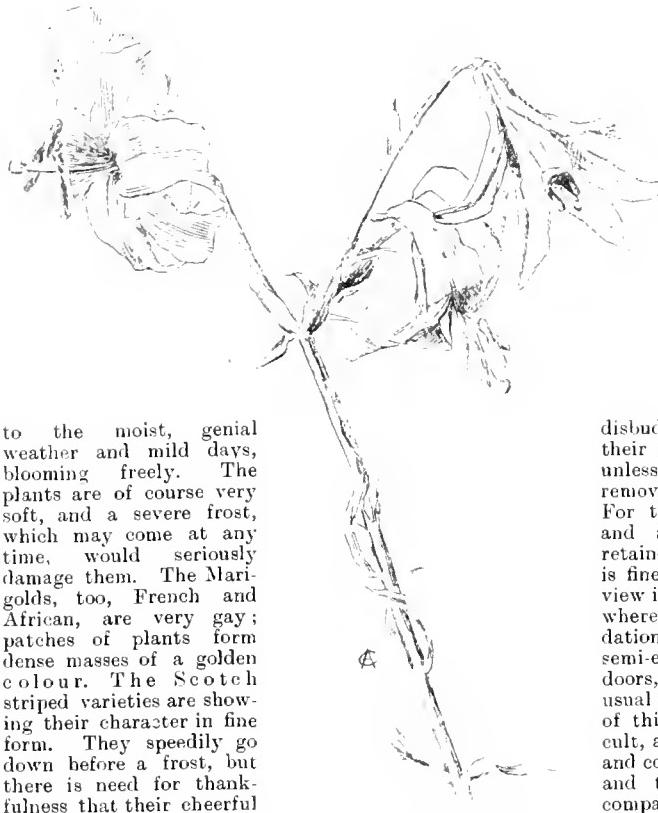

singular, owing to the fact that the inflorescence is most attractive, and in the autumn and early winter months it is for this reason much admired. It forms a bold tuft of Sedge-like leaves from 12 inches to 18 inches long and from 1 inch to 2 inches wide, while the flower-scapes, which well overtop the foliage, bear several flower clusters, which are lightly and pleasingly arranged. The flowers, with their attendant scales, are of a warm pinkish red colour, tipped with white filaments, and a plant in a 6-inch pot carrying several spikes forms such a distinct feature that it would doubtless receive far more attention if better known. This Carex was introduced in 1883 from Southern China, and requires the temperature of a warm greenhouse or intermediate structure. It is at present very uncommon, but this would not be the case long if its merits were more generally known.—H. P.

**A few words to fruit correspondents.**—Some time ago you were good enough to adopt a suggestion of mine that correspondents, when speaking of the growing of hardy plants, should also mention the locality. May I now suggest that they should, when speaking of fruits, also mention the soil. In your issue of the 18th ult. much space is devoted to Apple culture, but though it is pointed out that so many persons try the wrong Apple for their particular soil, no attempt in the article on page 260 is made to assist your readers in avoiding that error. It always seems to me that for the same reason the reports by the various colleges on the result of experiments with artificial manures are also useless, for that which is suited to Horsham clay is not suited to my sand.—H. S. [A very good suggestion. Will our correspondents who send articles about fruit kindly note this.—ED.]

**Californian Plums.**—I wonder how many readers of THE GARDEN interested in fruit culture recently saw in shops or markets Californian Plums in small chip punnets or baskets, margined with tin to keep them together, and each one holding 6lb. of really fine black heavily-bloomed freestone plums. Apart from the almost perfect appearance of the fruit and their excellent eating quality for this time of the year, I could but note the excellence of the packing method shown, an example a few of us may be quick enough to detect, but which, out of all our Plum growers, so few, if indeed any, take to heart. We send our Plums to market in big baskets, tumbling them about very roughly with all the bloom and beauty rubbed off. These Californians had come thousands of miles, yet in their baskets looked as if just gathered from walls. There were three layers in each basket, each of three dozen fruits. Between each layer was tissue paper, and a piece tied over the top. All fruits were on end. I purchased these fine Plums on the 20th ult. at 3½d. per lb.—A. D.

**The edible Passion-flower (*Passiflora edulis*).**—The edible Passion fruit, illustrated in THE GARDEN of the 18th ult., is known as Roberts's variety, and I believe Mr. Roberts, of The Gardens, Tan-y-bwlch, Merionethshire, was one of the first about here to grow it in quantity. The plants, six in number, were raised from seed six years ago, and have been planted in their present position four years. They now cover the back wall of a late viney, and when photographed in June were carrying over 800 fruits. The soil is loam and a little lime rubble, but I think any good garden soil will suit them provided that they are assisted with liquid or artificial manure after the fruit is set. We cut them back in the winter and dress with Gishurst or some similar insecticide. If grown in a viney or any other house with much heat they require artificial fertilisation, but when grown in a greenhouse in a somewhat cooler atmosphere they set freely themselves. Perhaps through being later in flower they get more assistance from the bees. In addition to being used for dessert the fruits are much prized here for jam.—HENRY WORTH, The Gardens, Wern, Portmadoc.

**Antirrhinums and Marigolds.**—Plants of these raised from seeds sown in spring and planted out in June and July are now, owing

LILIU TESTACEUM.

to the moist, genial weather and mild days, blooming freely. The plants are of course very soft, and a severe frost, which may come at any time, would seriously damage them. The Marigolds, too, French and African, are very gay; patches of plants form dense masses of a golden colour. The Scotch striped varieties are showing their character in fine form. They speedily go down before a frost, but there is need for thankfulness that their cheerful golden tints are preserved to us so long. Canterbury Bells, which have seeded, are starting to produce a second crop of flowers, and the spikes of Pentstemons are still remarkably fine.—R. D.

**Lilium testaceum.**—A delightful Lily is this, and one that succeeds well in most gardens. When *Lilium testaceum*, or *L. excelsum*, as it is sometimes called, is in bloom it can be confounded with none other: the colour of its flowers is a pleasing nankeen or buff, against which the brightly coloured anthers stand out conspicuously. The height to which this Lily will grow varies considerably, according to situation and treatment; it will reach a height of 6 feet or more under favourable conditions. The leaves as a rule remain until the flowering season is over, and *L. testaceum* is therefore well adapted for pot culture; as the flowers are pleasantly and not powerfully scented they can be freely used for decorative purposes.—A. C.

## CHRYSANTHEMUMS.

### SEMI-EARLY VARIETIES.

**E**ARLY-FLOWERING Chrysanthemums are increasing in popularity. There is a class, however, which is neither early-flowering nor mid-season, but which is of great value in the interval between the periods of flowering just mentioned. From the close of the first week in October until the first few days of November Chrysanthemums of good and distinct colours and pleasing and varied forms are always in demand, but for some reason at present unexplained little has yet been heard of this group. These semi-early kinds have much to commend them, and when once their cultivation has been taken in hand it is quite safe to predict a successful future for them. In sunny and sheltered positions they succeed remarkably well, but in less favoured situations the same measure of success does not attend one's efforts. It is as plants for pot culture that the semi-early varieties are seen to advantage, as they may be placed under glass with the advent of severe or disagreeable weather and flowered without artificial heat. During the greater part

of October these plants develop their blooms with little or no inconvenience from the atmospheric or climatic conditions prevailing at the time, and so long as the plants are not unduly crowded, and the cool glass structure is freely ventilated, the display is usually as charming as one could well desire. Unlike the early-flowering border varieties, which appear to do so much better when they are grown without disbudding, these October-flowering varieties give better results when the plants are partially

disbudded. Some of the sorts develop their buds in such dense clusters that unless the more crowded ones are removed good results are impossible. For this reason the most prominent and also most promising buds are retained, and the display as a result is finer, no matter from what point of view it is regarded. It is a good plan where labour is scarce and accommodation limited to plant a number of the semi-early kinds in an open position outdoors, and lift them just before the usual time for housing. To place plants of this description in pots is not difficult, and if the weather is fairly moist and cool at the time they may be lifted and transferred to large pots with comparative ease. Grown in the open border all through the summer and early autumn the plants develop into

quite large bushes, so that a few dozen plants treated in the manner just described are quite sufficient to maintain a supply of cut flowers for a long time. There are many inferior kinds in commerce, the colours in some instances being very poor.

The following list, however, includes several varieties which may be regarded as promising novelties. Special attention is drawn to the fact that these plants should be flowered from a terminal bud selection, by which means the colours are better in every way and the proper period of flowering is assured. Damping of the blooms, too, is hardly ever seen in those developed from a terminal bud selection, and their lasting properties are undoubtedly.

*O. J. Quintus.*—A Japanese flower of exquisite form, flowering at every joint in the long stems: colour, a pleasing soft rose-pink; wonderfully free flowering. Height about 4 feet.

*White Quintus.*—This is a pure white sport from *O. J. Quintus*, and produces freely elegant sprays of pure white blossoms. In all other respects but colour it is identical with the parent.

*Notaire Groz.*—For some reason this plant has been described as of straggling growth, but such a description is an injustice. The plant is taller than most other varieties, attaining a height of rather more than 4 feet. Long and elegant sprays of charming silvery mauve-pink flowers may be gathered, and these are most useful for vases. The plant comes into flower in early October.

*Bouquet de Feu.*—This is a very pretty little variety, which attains a height of about 18 inches to 2 feet. Its habit is sturdy and branching and yet compact. Each flower is developed on a good foot-stalk, and when the plant is at its best it is indeed a picture. Colour, bronzy terra-cotta; period of flowering, mid-October till mid-November.

*Harmony.*—A novelty distributed last spring. As an October-flowering variety it will be highly esteemed, as its colour, a rich bronzy terra-cotta, is popular. The form of the flowers, too, is pleasing, and the habit of the plant sturdy and bushy. Height about 2½ feet.

*Etoile de Feu.*—This has gained notoriety for the

richness and brilliance of its scarlet-crimson flowers. The flowers are not coarse or too big: as a matter of fact they are ideal for decoration, and should prove very useful for late October and early November displays. The plant is about 3 feet in height, and possesses a habit of growth second to none for cut flower use.

*Godfrey's Pet.*—A charming dwarf and compact plant, literally studded with pretty bright yellow blossoms when partially disbudded. Height not more than 18 inches. On terminal buds it is an October-flowering kind.

*Roi des Precoces.*—Though this plant has been in cultivation for many years, except for market, its culture has been much restricted. For late October use it has an especial value, as its deep rich crimson colour is very effective and the form is pleasing. Habit bushy; height about 3 feet.

*Vivid.*—In this variety we have an ideal decorative plant. Each flower is borne on a useful length of sturdy foot-stalk, and the plant flowers in profusion. Colour, brilliant chestnut, with golden bronze reverse. Height about 4 feet. In flower in late October.

*Mme. la Comtesse Foucher de Cariel.*—For years this variety has been regarded as one of the best for the border in mid-October, and though many good things have been introduced in recent years it still maintains its reputation. It is a mistake to disbud. Colour, orange, with yellow reverse. Height, 2 feet. Habit bushy; very free flowering.

*De la Guille.*—An introduction of 1896, and still one of the best. It is almost unique on account of its colour, which may be described as rich apricot. The flowers are very pretty, and make an effective display when open. Habit bushy and sturdy. Height about 2½ feet. In flower from early October.

*Gladys Rout.*—Another white variety in this brief selection seems to be necessary, and this is quite distinct in form to all others. The flowers are of medium size, and to be seen at their best the plants should be freely disbudded. Height rather less than 3 feet. Habit fairly bushy and sturdy. Period of flowering, latter part of October.

*Highgate, N.*

D. B. CRANE.

### SOME BORDER CHRYSANTHEMUMS.

A RECENT visit to Earlswood reminded me of the great interest that is now being taken in early Chrysanthemums by a certain section of Chrysanthemum lovers. For those amateurs who have no glass accommodation, and for others who like to brighten up their borders at this season of the year, early Chrysanthemums, but especially those of the Japanese type, afford ample scope for the best decorative effect. Mr. W. Wells has a very extensive collection, and he grows them in an open field away from his nursery where they get the full benefit of the open air. The result is at once effective, and affords means of raising healthy stock. Besides large numbers of already well-known popular sorts might be mentioned several novelties likely to interest admirers of these early sorts.

*Goacher's Crimson* is one of the most useful, its colour is rich, the plant very floriferous, and the blooms of good size; *Rosie* is new, similar in form but rather smaller, colour golden terra-cotta, with a golden centre; *Victor* is another new one, a pure white attractive little Japanese; *Polly*, also a novelty, is a Japanese of good size, colour deep golden yellow, strongly shaded chestnut-crimson; *Winnie* is a very double Japanese, with long florets, deep golden-orange tinted carmine. Another of these new things is *Nellie*, a fine pure golden yellow Japanese with long drooping florets. *Gertie* is not unlike the old reflexed variety *Golden Christini* in form and colour, but has a decided shading of pink. Several others, older kinds, which have often been referred to in the columns of this journal, are this season proving themselves to be well worthy of the commendations they have received.

## NOTES ON HARDY PLANTS

## ARENARIA BALEARICA.

**F**OR clothing the cool base of rock-work no plant of low stature is more satisfactory than this little Sandwort. It runs into the joints and over the prominences almost like a coat of thick green paint, so closely does it cling and so clearly does it show the form of the stone beneath, while in early June the hosts of little flowers, large for the size of the plant, deck it with sheets of purest white. It readily sows itself, and in a year's time a chance seed will grow into a pretty tuft.

## ZAUSCHNERIA CALIFORNICA.

COMPLAINTS have frequently been made from the North that this plant is useless for decorative purposes on account of the lateness of its flowering, and an earlier-blooming form, which is to be obtained at certain nurseries, has been recommended as far more useful. I have what I imagine to be the type, and this year paid special attention to its flowering period. The plants are growing in light soil in a narrow bed facing south backed by a wall. The first flower opened on July 22, and through August and September the bed was bright with scarlet blossoms borne with great freedom. Now (October 23) the plants are practically out of bloom, though they still carry some thirty flowers. In the spring I procured a plant of the early-flowering variety. In foliage it much resembled the form I already possessed, which is the one common in this neighbourhood, but the leaves were perhaps slightly more tomentose. The first flowers did not open until October, a fact doubtless due to the smallness of the plant. In colour they were rather brighter than those of the older batch, but as these were at that time less vivid than during the zenith of their display, no reliable comparison was possible. Next summer, by which time the new plant will have become thoroughly established, a definite conclusion as to earliness of flowering should be arrived at. I may add that no season could have been more adverse to the Zauschneria than the dull and wet summer which has just ended.

South Devon. S. W. F.

## THE FLOWER GARDEN.

## HARDY FLOWERS FOR CUTTING.

**A**T this season of the year, when planting is in progress, it may not be out of place to call attention to a few good hardy perennials for cutting in their respective seasons, ranging from March till the beginning of November, especially as there is an ever-increasing demand for them in all gardens, whether large or small. When this is the case, and it is known that the amount of cutting will be prejudicial to the display in the flower garden, I should suggest the advisability of devoting a reserve border or piece of ground to the growth of such plants. A portion of an old slip garden deeply worked and well supplied

with thoroughly decomposed manure will be admirable for the purpose. In such a position there is no necessity for any consideration in the way of effective grouping. Utility is the main object, and so Daffodils, Iris, Montbretias, and dwarf plants may be planted in alternate lines with larger things, such as Phloxes, Asters, and Sunflowers. The object is to economise space and to provide additional room for late flowers. With regard to the furnishing of such reserve ground and the mode of propagation, if special things are wanted they must first be acquired and increased by offsets, cuttings, or division, as the case may be, but the majority may be obtained from seed sown thinly in prepared beds some time in April, and the seedlings afterwards transferred to permanent quarters; or, better still, prick out the seedlings in beds and plant late in autumn. In the case of such seedlings one has naturally to take the bad with the good, but of nearly all plants required really good material for cutting can be obtained if seed is secured from firms who make a speciality of hardy plants. Before offering a list of plants available I should like to note that, although it might doubtless be altered in some cases for the better and also considerably increased, it is just a chronicle of things which have served us well. It may be said that of bulbs

DAFFODILS should be omitted, but I cannot leave them out. Those sorts only, however, should be utilised which will multiply both in offsets and flowers with each succeeding season and hold their ground for many years. Sorts like Queen Bess, Stella superba, Barri conspicuus, Telamonius plenus, and the May-flowering poeticus will in their respective seasons be found very useful for such work. The last on the list will produce more flowers from a given area than anything else that may be grown. About twenty-five flowers on an average were obtained last year from clumps that are the result of single bulbs planted seven years ago.

*ARABIS ALBIDA* FL.-PL is a charming flower, like a miniature Stock, throwing up long spikes in early spring. Very useful for small vases and buttonholes, and quite as easily grown and more vigorous than the well known single form.

DORONICUMS.—With the great wealth of yellow furnished by the Daffodils it may be that the varieties of Leopard's-bane are hardly required, but room must be found for the one known as Harpur Crewe. Once planted in good soil it will hold its own for several years; lift when the clumps show signs of decadence, select the strongest crowns, and replant in a bit of new soil.

AQUILEGIAS must on no account be omitted. They are always in request, and when well arranged, either alone or with neat foliage, there is a dainty appearance about them hardly equalled by any hardy flower. It is, fortunately, one of those things easily and cheaply grown, seed obtained from a good firm produces charming flowers in great variety. Sow early in April, and if when the seedlings are getting crowded permanent quarters are not ready transfer to prepared beds till the autumn. Very nearly the same remarks with reference to obtaining really good seeds, cultural requirements, and value in a cut form, apply to single

PYRETHRUMS. If a bit of seed is sown annually some really first-rate things are generally obtained, which may be increased to the exclusion of indifferent forms. One cultural note in connexion with both the above two plants may be added. They have a tendency when in permanent quarters to lift themselves above the soil. If this is noticed lift in late autumn and replant firmly at a lower level, with the addition of a bit of good soil about the roots. If single Pyrethrums are preferred it is not necessary to have many varieties. There are few better in their respective shades than Apollo (pink), James Kelway (scarlet), Mrs. Bateman Brown (deep crimson), and Queen of the Whites.

ARENARIA BALEARICA BY PATH OF SMALL ROCK GARDEN.

YUCCA GLORIOSA IN GOGAR PARK GARDENS,  
CORSTORPHINE, MIDLOTHIAN.

COREOPSIS GRANDIFLORA and GAILLARDIAS may both be treated as advised for Pyrethrums, and will furnish an abundance of flowers from early summer until late in autumn. The whole family of

IRIS are so useful that a selection is somewhat difficult, but for the purpose under consideration perhaps the varieties of Xiphium are the best. They are easily grown, will continue to flower well in the same quarters for many years, and are comparatively cheap. A great variety of beautiful shades can now be purchased at prices ranging from 10s. to 20s. per 1,000. A batch of these should if possible be planted on a north border during the season of flowering; cutting is then very considerably prolonged. The present season has shown

MONTBRETIAS in their true character. Hitherto they have been rather quickly over with us, that is, on light, dry borders. This year under cooler conditions and with more moisture they have been in flower nearly three months, and are still good (October 21). From the well-prepared reserve border very fine spikes have been obtained. There are now many varieties of M. crocosmiaeflora in beautiful shades, but the type will answer all requirements for cutting. Lift every third year, select and replant the strongest corms.

PHLOXES I have not yet tried from seed,

having acquired some excellent sorts from cuttings, and no great number of varieties is necessary for the supply of cut blooms, the main consideration being that several distinct shades of first-rate quality are represented. There is an impression that Phloxes will not last well in a cut state, but this is quite erroneous. The old common sorts would not, but large, firm-pipped varieties are first-rate for large vases. Snowdon and Avalanche are good early and late whites, and other good sorts in different shades are La Sicle (pink), Etna (salmon), Cresus (crimson), Cœur de Lion (carmine), and Pharou (lilac). The portion of reserve border where Phloxes and other deep and strong rooting things are planted should receive a heavier manure than that apportioned to Daffodils, Montbretias, and the like.

PENTSTEMONS are much appreciated and valuable for late cutting. Fine spikes are now (the third week in October) available from seed sown early in April. Pentstemons are flowers that come remarkably good from seed, that is if the seed is obtained from a trustworthy source. A peculiarity of this year's seedlings is that all the flowers are white-throated. The small flowered

P. BARBATUS COCCINEUS is also very useful, and comes from seed. Some two or three sorts of

ERYNGIUM should be included in all collections for cutting because of their unique appearance. It is, however, hardly necessary to devote space in the reserve ground to them. They will grow on any spare poor border.

SUNFLOWERS, at least some of them, are the better for annual lifting and replanting, choosing strong crowns. If confined to two I should choose Helianthus Miss Mellish and Helenium nudiflorum; the last-named is a grand subject for tall vases. With the enormous number of varieties of perennial

ASTERS now in commerce it is somewhat difficult to make a selection of a few that would be best for cutting, and I have grown very few of the newer forms. My favourites are cordifolius elegans, Novi-Belgii Robert Parker, vimineus, and Tradescantii.

GYSOPHILA PANICULATA and STATICE LATIFOLIA must not be omitted, as in their respective seasons they are in ever-increasing demand. Both come well from seed, and it is an interesting characteristic of the Sea Lavender that hardly any two seedlings are the same. They vary not only in colour, in size of individual tiny bloom and panicle, but also in the season when they are at their best—the last a valuable feature. The last flower on my necessarily imperfect list is

LAVENDER, of which a few rows should always be grown. There are few households that do not welcome the late summer gatherings of Lavender. I should like to add that all plants grown for the purpose under consideration should be of vigorous habit and free-flowering, miffy things should not be included.

Claremont.

E. BURRELL.

#### YUCCA GLORIOSA.

MR. A. FINDLAY, the Gardens, Gogar Park, Corstorphine, Midlothian, kindly sends the following note about *Yucca gloriosa*, which, to judge from the accompanying illustration,

evidently thrives well under his careful treatment. "We have three plants similar to the one represented by the enclosed photograph, all of which I propagated fifteen years ago. They have come into flower together, and are now (September 22) a beautiful sight. The flower-spikes are from 5 feet to 6 feet high, each spike carrying about 260 of its pure white blooms."

#### AUTUMN-FLOWERING CROCUSES.

THOUGH these beautiful winter flowers are neglected, still I think there are signs that they are beginning to be more sought for. The winter and autumn kinds flower just when winter is at hand, hence they are of greater worth by comparison. For example, what a veritable storehouse of beauty and interest do these combine, and how suitable they are for the lady amateur who is only lucky enough to possess a cold greenhouse, for in such a structure of course no heat can be turned on. More than this, these Crocuses are just the bulbs for such a house, and any artificial heat spoils them entirely. It is when the observer is brought into this closer touch and all the beauty and refinement is seen to such advantage that the Crocuses of other times appear rough-looking, and possibly a little vulgar, too. Still, there is room for these, and even the sparrows do not object to a taste of them in season. Perhaps the most important item of all is the long flowering season of the species. Starting in early autumn, they maintain an unbroken chain of flowers almost through the winter months and even to early spring. Thus it is that a collection affords unceasing pleasure, and in the manner indicated the flowers could be enjoyed at all times. For the same reason of continued flowering the making of a display at any one season is somewhat difficult from the exhibition standpoint, though a better display could be got together perhaps in the month of October than any other time by the autumn kinds. The best way to exhibit the species of Crocus is to grow them in pans; in other words, let the plants be duly prepared for the display, so that visitors may see them in all their beauty and in such a way as to carry conviction at a glance.

Among the few nurserymen who make a speciality of the species of Crocus and take material interest in their cultivation are Messrs. Barr and Sons, Covent Garden and Ditton; indeed, just now at the latter place are many beautiful kinds that cannot but delight the visitor. There are also some pretty groups at Kew, sometimes in small beds, at others in the rock garden or just appearing perhaps from amid grassy blades on the lawn. Quite at home and delightful in any position, no plants are more easily cultivated; they delight in any quite open sandy loam, and, what is equally to the point, they are cheap enough to be grown in masses and quite freely. I think no one having taken them in hand will readily give them up. A dozen bulbs may easily be grown in a 6-inch pot or in one of those equally serviceable art pots that are at any moment ready for the transfer to sitting or drawing-room when the plants are in bloom. In this way the Crocuses should appeal to all flower-lovers, the more so because all their beauty is not instantly revealed, and it is a moot point whether the fully-grown bud or the open flower is the more pleasing. Certainly in the latter stage all the rich variation of the finely-coloured anthers is well seen; in some kinds it is quite a feature and a decidedly conspicuous one. The following are some of the most beautiful now in bloom:—

*Crocus speciosus*.—This is showy in colour and bold in form, often reaching 9 inches high. The colour is violet-blue with darker lines, the orange-red anthers being very striking. The segments are fully 2 inches long. An invaluable plant. The flowers, too, emit a powerful fragrance—a fact rarely noted. There are one or two varieties of this species, but it is doubtful if any surpass the type in beauty and intrinsic merit.

*C. pulchellus*.—Palest blue, with azure-blue lines

on both surfaces. The rounded segments are  $1\frac{1}{4}$  inches long, and have a small golden-orange crest at the base; 4 inches high. Very beautiful.

*C. medius*.—Flowers of a violet-purple hue, conspicuous by the exceeding glossy character externally: segments  $1\frac{1}{2}$  inches long, feathered and lined near the base; anthers mahogany-red and very striking; height 5 inches; a showy and handsome kind.

*C. nudilorus*.—A well-known species of vigorous growth; colour a light violet; the bluntly rounded segments nearly  $1\frac{1}{4}$  inches long, with almost white base; anthers orange-red; 6 inches high.

*C. zonatus*.—This is certainly one of the gems, and no collection should be without it. The segments are  $1\frac{1}{2}$  inches long, palest mauve in colour, delicately lined on both surfaces, while at the base internally a nearly V-shaped light golden crest further distinguishes this dainty kind; height 4 inches.

*C. hadriaticus* and its variety *chrysobelonius* are both white-flowered, the latter having segments  $1\frac{1}{2}$  inches long and acutely pointed. To both kinds the base is somewhat clouded with yellow, and the anthers are conspicuous; 3 inches high.

*C. asturicus atropurpureus*.—This handsome Crocus is given the preference in this case as being a decided advance, and superior to the type. The satin-like glossy texture of the outer segments is a most effective characteristic, and in the rich purple-violet shade most striking. The flowers are nearly 2 inches long, graduated to a lance-shaped point, and freely lined on the lower half of the flower; anthers orange-red. A sturdy and vigorous kind 4 inches to 5 inches high.

*C. iridiiflorus*.—This is a large and handsome Crocus, with flowers of a rich deep purplish blue externally and pale lilac within; a bold and showy species of much merit; height 6 inches.

*C. longiflorus* is a very beautiful species of a pleasing and soft rose-lilac hue. The effect of this when naturalised is very pretty, and it is not only well suited to the purpose, but, being also one of the least expensive—indeed, it is perhaps the cheapest—should be freely used. It is sometimes catalogued as *C. odorus*; height 5 inches.

*C. cancellatus cilicicus* is a beautiful flower of a pleasing lilac tone. There is also a second variety called *C. c. mazziaricus*, which is white-flowered, with gold anthers; it is, however, less free in flowering, though very pretty; height 4 inches to 5 inches.

These, while not exhausting the list of early and late autumn-flowering kinds, are some of the most noteworthy, providing variety and beauty of a kind not afforded by any other group of hardy flowers. Patches of these peering through a thin carpet of some mossy Saxifrage will beautify the rockery at a time when flowers in that department are rare.

E. JENKINS.

#### NOTES FROM SWANSWICK.

In a nursery ground near by there has been for some weeks past a group of *Liatris pycnostachya*, which seems to have attracted a great deal of attention, being visible in all its gaiety from the high road. This is quite a noticeable plant, even among a large collection, and with its long thick bright violet-purple spikes almost suggests a small *Eremurus* as far as form goes. It is infinitely handsomer than *Liatris spicata*, but I find the latter exceedingly useful from its prolonged flowering. It has been good ever since June, and still has some flowers on hand, which, as there is a group of three plants in front of a pyramidal

Bay tree, show up well against the dark glossy green. In this soil—rich loam on clay—it grows twice as high as it did on the black soil of the suburb garden from which it came (Newport). It would be interesting to know whether any profit remains to the Rose grower who has sold his plants by auction. Excellent bushes of full size, with an abundance of fibrous roots, of such varieties as Caroline Testout, Magua Charta, La France, and others, at 1s. 6d. and 2s. for six of a sort, do not seem to leave much margin, neither do Crimson Ramblers at 2s. 6d. the half dozen, and standards of various kinds at 4s. 6d. for the same number. I always thought the French Roses a marvel of cheapness, although they are apt to be small above ground, though usually well furnished with fibrous roots; but these auction prices are yet lower, and for larger stuff. The wet summer has prevented Roses about here from ripening much—if at all—so far, and very few look ready to move, the few established in this garden being for the most part still in flower.

The Cactus Dahlias are still very good, and as they are all of the newer sorts, which hold up their flowers well, and have, further, been

have still produced famous crops, and the want of sunshine does not seem to have affected them to any sourness. Taken all round, the Apple is a glorious thing, and king of fruits. Talk of your Mangoes and tropical flavours, your Grape fruits and bready Bananas, and watery Water Melons, an Apple off the dewy ground, perhaps not one from a fruit room shelf, eaten in October sunshine, there and then, is worth the whole vaunted boiling. I think it is perhaps the crispness of this new fallen Apple that gives it its pre-eminence. To feel one's front teeth crunch through its spirited juice and substance is pure, if greedily animal, enjoyment not to be shared by the eater of Peaches or the Pear epicure.

In Somerset we plant Cabbages with the waxing moon, certain that so they will grow and be lusty. If we put them in, or set any flower or fruit tree, when her white ladyship was gibbous in the attenuating scale, our labour would be vain, for that which we planted would but wane with Diana. Just so, when Horse-radish needs, as this engagin' plant generally does, to be eradicated, the right time to begin is in the moon's eve of the veil.

Another West Country tradition forbids Lilies of the Valley to be set in a bed under pain of not distant death to the operator. Three years ago I did this thing with my hand that writes, and it is still writing; but the superstition was somewhat borne out, in that loss of health is akin to the worse—or much better—event. As to the waxing and waning, it might be advisable to take a census. M. L. W.

A NEW WHITE HEATHER (*ERICA VULGARIS ALBA VAR. GRACILIS*).

carefully thinned out, they do not really merit the censure cast upon their race by a well-known garden enthusiast, who, in the course of a flying visit here a few weeks ago, discouraged us very much by saying that when you grew these plants and wanted a few blossoms for showing you had to spend your valuable time peering and searching about in yards of foliage to find them. No such quest would be needful here, from the lovely Rosine and deliciously cool-hued Prince of Yellows to the ever-charming, if elderly, Countess of Lonsdale, they are all full of flowers, and as gay with colour as a charity bazaar.

There are many consolations in a heavy soil. Perhaps I shall not feel so gracious towards it next spring; but at present it is appreciated. The small black dogs we grow here riot over the beds without leaving a footprint, and the village cats they scatter are powerless for much evil. One cannot go on the land to dig it in wet weather, it is true; but it is beautiful to see the great clods the last digging turned up melt down, under a downpour, into good surfacing, all friable and rich. Some of the Apple trees, gnarled old things suffering from many years of overgrowth and underfeeding,

at the recent Edinburgh show of the Royal Caledonian Horticultural Society Mr. T. R. Hayes, nurseryman, of Keswick, exhibited a new white Heather (*Erica vulgaris alba var. gracilis*), which then received an award of merit. We learn from Mr. Hayes that it has been in flower since August, so that it remains in bloom considerably longer than *Erica vulgaris alba*. The foliage is very similar to that of *E. v. Serlii*, dark green, and of a feathery appearance. Its spreading habit will make it useful to associate with sturdier growing sorts, and no one could wish for a better representative of the Scotch Heather with which to adorn their rock gardens. We understand that His Majesty the King has been pleased to accept plants of this new Heather for the gardens at Sandringham. This new white Heather was exhibited for the first time at the Preston Guild Show on September 5, when it was unanimously awarded a gold medal.

#### THE CRABS.

At this season few trees are more attractive than the Crabs with their brightly coloured fruits. Of late years a few very pretty varieties have been added to this class. Not only in the autumn are these trees beautiful, but in May and June, according to the locality, the flowers are lovely. In the far North and on the Scottish border in the early part of June I saw some beautiful trees of the Dartmouth and John Downie Crabs. These

THE WHITE CAMPANULA CARPATICA.

two are great favourites, especially the last-named, and as this flower late it is not often injured by frost.

Few trees are more welcome for their flowers, and as the Crab will thrive well in most places it is worth extended culture. I recently saw some trees of the Fairy Apple with pretty yellow and red small fruits. They were grown as bushes, not much pruned, and were most effective in that form. They fruit freely, but there can be no doubt that the best method of culture is to grow them as standards with ample head room.

I have mentioned two of the best varieties, and to these should be added the older scarlet Siberian or Cherry Apple, the Orange Crab, a pale golden fruit, also a new form of this variety, the oblong Crab, which is very distinct, and an American introduction, the Transparent, is a very nice yellow fruit and a larger kind; the Transcendent, an oval red and yellow variety, is very telling grown either as a bush or standard. There are some large fruited, such as the Montreal Beauty or Mammoth Crab, also the lesser known Malakovna, a large scarlet variety, and there are some newer introductions, such as General Grant and Hesper Rose. Of these I have no experience, but there are no lack of varieties. I am not sure that greater size is needed. I think the small free fruited very pretty for the purpose noted. Messrs. Cheal have a beautiful fruit in their Cheal's Crimson Siberian. This is a charming variety, and quite distinct from the old form; it is a very valuable addition to this class, and bears remarkably well. The fruits are very bright and much valued in the autumn. There is a weeping variety very suitable for the enclosed garden—I write enclosed garden, as where there are cattle they damage the trees badly when in fruit, so that this should be borne in mind when planting. The variety referred to is called Elise Rath; it is very effective grown as a standard on the fringe of shrubberies.

as there are now so many beautiful varieties, seems as imperfectly to be understood as are the merits of its fruits for preserving.—ED.]

#### CAMPANULA CARPATICA.

This is one of the best and most easily grown of the Bell-flowers. Its best use in garden borders is at the extreme edge, and if that edge is of stone it also grows willingly in the joints. As a plant for the rock garden it is admirable, and is excellent in walls and the crevices of rough stone steps. The colour of the type is the rather pale lavender-blue of so many of its kind, but the white variety is also indispensable. It is a plant for every garden.

#### THE ROSE GARDEN.

##### THE PERGOLA IN ENGLISH GARDENS.

By MISS Jekyll, V.M.H.

**I**T is only of comparatively late years that we have borrowed the pergola from the gardens of Italy. Borrowed is perhaps, in its complete sense, not quite the right term to use, for borrowing implies returning or repaying, whereas, having borrowed the pergola, we have certainly kept it for our own. Its main use in Italy is as a support for Grape vines and at the same time to give shade to paths. Here we use it, not only for shade, but as an important feature in garden design and for the display of the best plants of rambling growth, whether for beauty of flower or foliage. In the old English gardens of Tudor times there was something

that approached the uses of the pergola in the pleached alleys of Hornbeam or some such tree trained on a framework of laths. But these shaded alleys were slow of growth and wasteful of labour, and did nothing to display the beauty of flowers. Our adaptation of the pergola gives a much quicker and better addition to the delights of the garden, for we have our shady walk, and in addition some of the most charming pictures of flower beauty that the garden can be made to show. It is therefore no wonder that a pergola or something of the kind is now wanted in almost every garden.

Before considering how it is to be planted it may be well to give an idea of the different ways in which it is made. The simplest form of pergola in Italy is made of stout poles guiding and supporting the trunks of the vines, connected across the path by others of less diameter, with a roofing of any long rods laid lengthways along the top. This is repaired from time to time by putting in fresh uprights or other portions in the careless happy-go-lucky way that characterises the methods of domestic and rural economy of the Italian peasant or small proprietor. But often in Italy one sees solid piers of rubble masonry coarsely plastered either round or square in plan, or even marble columns from ancient buildings. These have a more solid wooden beam connecting them in pairs across the path, and stouter stuff running along the length.

For our English gardens we have the choice of various materials for the main structure. If the pergola is to be near enough to the house to be in any sort of designed relation to it, and especially if the house be of some importance, the piers should be of the same material as the house walls—brick or stone as the case may be. Fourteen-inch brick piers laid in cement are excellent and easily made. Such piers may be said to last for ever, and if it is desirable that they should not be red, or whatever may be the normal colour of the brick used, it is easy to colour them in lime-wash to suit any near building. For association with refined brick building bricks are sometimes moulded on purpose of thinner shape, either square or half-round in plan, the latter being for piers that are to shew as round columns. Brick, stone or marble, or wooden columns are also used in refined designs. For more ordinary work the piers may be of Oak trunks of a diameter of 8 inches to 10 inches. These if tarred or charred at the butts high enough up to show a charred space of 1 foot above the ground-line, and put into the ground like gate-posts, will last from fifteen to eighteen years, or have about the lifetime of an ordinary field gate-post. A better and more enduring way is to have the posts of Oak 8 inches square, set on squared stones that stand 1 foot out of the ground, with a stout iron dowel let into the foot of the post and the top of the stone. Unless the appearance of the Oak post is desired there is little if anything to choose in point of cost between this and the solid brick pier, as the Oak has to be squared and the plinth shaped and bedded on a concrete foundation. In most places local custom and convenience of obtaining local material will be the best guide in choosing what the pergola is to be made of. Larch posts are nearly as good as Oak, and Larch tops are the best of all materials for the top roofing.

Whatever may be the kind of post or pier, it is important to have them connected by good beams. The beam ties the opposite pairs of posts or piers together across the path. In the case of brick or stone piers it should be of Oak or Larch 7 inches to 8 inches square, not quite

horizontal, but slightly rising in the middle. This is of some importance, as it satisfies the eye with the feeling of strong structure, and is actually of structural utility. It is of course possible to make a pergola of iron with very flat arches, and supporting rods and wires or wire netting for the top; but it is the material least recommended and the one that is the least sympathetic to the plants: indeed in many cases contact with the cold iron is actually harmful. A modification of the continuous pergola is in many cases as good as, or even better than, the more complete kind. This is the series of posts and beams without any connexion in the direction of the length of the path, making a succession of flowering arches; either standing quite clear or only connected by garlands swinging from one pair of piers to the next along the sides of the path, and perhaps light horizontal rails also running lengthwise from pier to pier. This is the best arrangement for Roses, as they have plenty of air and light, and can be more conveniently trained as pillars and arches, while the most free-growing of the Ayrshires and hybrid multiflora ramblers willingly make swinging garlands. Roses are not so good for the complete pergola.

To come to the plants, and to take first the cases in which most shade is desired, with beauty of flower or foliage, the best are certainly Grape Vines, Aristolochia, Virginia Creeper, and Wistaria. They are all, except Virginia Creeper, slow to grow at first, but in four years they will be growing strongly. Vines should be planted a fair size, as large as can be had in pots, or two or three years will be lost at the beginning. Aristolochia, and especially Wistaria, though they grow fast when established, always make a long pause for reflection at the beginning of their new life's journey.

It is therefore a good plan, when a pergola is planted with these as the main things for its future clothing, to plant at intervals several Clematis montana, or even the common but always beautiful C. vitalba. These, especially C. montana, will make a fine show for some years, while the slower plants are making their first growth; and as C. montana has in many soils not a very long lifetime, the best it can do will be over by the time the permanent plants are maturing and wanting the whole space. The Sweet-water Vines of the Chasselas class, known in England as Royal Muscadine, have foliage of excellent form that is beautiful in autumn with its marbling of yellow.

The Parsley or cut-leaved Vine is another desirable kind. *Vitis cordata*, the sweet-scented Vine, has large wide leaves that give ample shade, and a strong habit of growth, and flowers that in hot sunshine freely give off their delicious scent; while for gorgeous autumn colouring of crimson and yellow the Vine commonly known as *Vitis Coignetiae* is quite unequalled. There is also

the Claret Vine, whose leaves turn a low-toned red in late summer and autumn.—*Reproduced by permission from the Journal of the Royal Horticultural Society.*

(To be continued.)

### SELECTIONS OF ROSES.

(Continued from page 302.)

#### EIGHTEEN HARDEST CLIMBING TEAS, HYBRID TEAS, AND NOISETTES.

FOR somewhat cold districts the following Roses will be found excellent for walls, and most of them can be grown on pillars. Those marked with an asterisk (\*) are good for north or east walls:—

A PERGOLA OF PINK RAMBLER ROSES.

\*Aimée Vibert, white; \*Cheshunt Hybrid, maroon-crimson; Climbing Belle Siebrecht, rich pink; Climbing Captain Christy, flesh; Climbing Souvenir de Wootton, rosy red; Desprez à fleurs jaunes, reddish buff; \*Gloire de Dijon, yellowish salmoo; \*Kaisserin Friedrich, lemon, shaded pink; Longworth Rambler, carmine; Mme. Alfred Carrière, flesh-white; Mme. Berard, salmon-rose; Mme. Jules Siegfried, creamy white; Mme. Marie Lavallée, white and rose; \*Pink Rover, pink; Reine Marie Henriette, rosy red; Reine Olga de Wurtemberg, brilliant red; Rêve d'Or, deep yellow; and Waltham Climber, No. 1, bright crimson.

#### THIRTY BEST HYBRID PERPETUALS.

From this useful group one may obtain Roses of delicious fragrance, glowing colours, and perfect

form. They are very hardy. When pruning cut back the strong growers to within 1 foot of the base, the weaker growers from 3 inches to 6 inches. Always cut down quite to the ground one or two of the oldest growths each year. This has a tendency to make the plant reproduce itself in a year or two. Sound, hard, one year old wood gives the best blossoms; the weak and pithy shoots should be liberally discarded. The following are all good kinds:—

Alfred Colomb, red; Alfred K. Williams, carmine-red; Beauty of Waltham, light red; Ben Cant, deep crimson; Charles Lefebvre, velvety crimson; Clio, flesh-white; Comte de Raimbaud, dark red; Crown Prince, purple; Duke of Edinburgh, vermillion; Dupuy Jamain, cerise; Eugene Furst, velvety crimson; Fisher Holmes, crimson-scarlet; Frau Karl Druschki, snow-white; General Jacqueminot, crimson; Jeannie Dickson, silvery rose; Mme. G. Luizet, pink; Mme. Victor Verdier, light crimson; Margaret Dickson, flesh-white; Marquise de Castellane, rose; Maurice Bernardin, crimson; Merveille de Lyon, white, shaded pink; Mrs. John Laing, soft pink; Mrs. Sharman Crawford, rosy pink; Pride of Waltham, flesh; Prince Arthur, deep crimson; Prince C. de Rohan, maroon; Rosslyn, flesh; Suzanne Marie Rodocanachi, cerise; Ulrich Brunner, cherry-red; and Victor Hugo, velvety crimson.

#### TWENTY-FOUR BEST PERGOLA ROSES.

Fast-growing Roses are in this case most appropriate. With few exceptions they are summer-flowering only. If autumn flowers be desired, plant some of the Teas and Noisettes in conjunction with the summer kinds. These latter need not be so vigorous, for if the supporting pillars were clothed with blossom in autumn a lovely effect would be obtained. Those kinds marked with an asterisk (\*) should only be planted if the aspect is fairly sheltered.

Aglaia, yellowish white; Prince Vibert, white; Bennett's Seedling, white; \*Claire Jacquier, orange; Crimson Rambler, crimson; Dorothy Perkins, pink; Euphrosine, blush-pink; Electra, yellowish white; Felicité Perpétue, white; Flora, pink; Gloire de Dijon, cream; Helene, violet; Jersey Beauty, lemon-white; Mme. Alfred Carrière, creamy white; Noella Nabonnand, velvety crimson; Paul's Carmine Pillar, carmine; Queen Alexandra, rosy pink; Reine Olga de Wurtemberg, red; \*Rêve d'Or, apricot; Ruby Queen, ruby-red; Ruga, flesh; Thalia, white; The Garland, buff; wichuriana rubra, red.

#### TWELVE BEST POLYANTHA ROSES.

These pretty little gems are very useful for bedding, or for potting up to grow on for conservatory decoration. Some of them are really as strong as Tea Roses, for instance Perle d'Or, but by hard pruning and slightly tying down they answer well for the purpose first named. They also make delightful low hedges.

Anna Marie de Montravel, white; Cécile Brunner, blush; Eugénie Lamesch, yellow; Gloire des Polyantha, deep rose; Katherina Zeimetz, white; Léonie Lamesch, coppery red; Mme. E. A. Nolte, chamois; Mignonette, pink; Perle des Rouges, crimson; Perle d'Or, nankeen; Petit Constant, reddish orange; Schneewittchen, creamy white.

#### TWELVE BEST RUGOSA ROSES.

This interesting group has come much to the front lately, and they deserve greater popularity. The following dozen are all first-rate:—

Alba, white, single; Atropurpurea, purple; Belle Poitevine, rose; Blanc double de Courbet, snow white; Chedane Guinoisseau, satin rose; Conrad F. Meyer, silvery rose; Fimbriata, rosy pink; Mme. Charles F. Worth, carmine; Mme. G. Brabant, white; Mercedes, flesh pink; Mrs. Anthony Waterer, crimson; Rubra, rosy red.

#### SIX BEST MOSS ROSES.

No garden is complete without a Moss Rose. Far too many worthless kinds have been sent out. We want a few distinct varieties. The following six are all good:—

Blanche Moreau, paper white; Common, pink; Comtesse Murinais, blush white; Crested, pink; Little Gem, rose; White Bath, pure white.

#### TWENTY-FOUR BEST HYBRID TEA ROSES.

Excepting that they produce a continuous mass of blossom, there are many individuals who would not care for the small-flowered kinds, such as Camoens, Marquise de Salisbury, &c., that form a large proportion of this popular group. In the following selection of twenty-four such kinds as are named above are omitted, and only those given that yield fine individual flowers, but which are none the less beautiful as garden Roses. They are as follows:—

Antoine Rivoire, rosy flesh; Augustine Guinois-sau, white, tinted rose; Bessie Brown, creamy white; Captain Christy, delicate pink; Caroline Testout, salmon-pink; Clara Watson, white, tinted flesh; Gloire Lyonnaise, pale lemon; Grace Darling, cream and pink; Kaiserin Augusta Victoria, cream, shaded lemon; Killarney, flesh, shaded

white; La France, silvery rose; Liberty, velvety crimson; Mme. Abel Chatenay, carmine-rose; Mme. Cadeau Ramey, flesh and yellow; Mme. Eugénie Boullet, salmon and saffron; Mme. Jules Grolez, silvery rose; Mme. Ravary, golden yellow; Marquise Litta, carmine and vermillion; Mildred Grant, ivory-white, flushed pink; Mrs. W. J. Grant, rosy pink; Souv. de Mme. Eugénie Verdier, creamy white; Souv. du President Carnot, rosy flesh; Viscountess Folkestone, creamy pink; White Lady, creamy white.

## THE FRUIT GARDEN.

### FRUIT TREES IN POTS.

#### HINTS FOR AMATEURS.

**T**HIS branch of fruit growing under glass appeals with greater force to the amateur lover of fruit culture than does any other aspect of this interesting art. By this method we perfect come into familiar and personal contact with the requirements of our fruit trees—talk to them, as it were, face to face. There is nothing hidden from our view—the roots even are familiar to us. In the autumn, some time during the month of October, every plant should be repotted, after which all we have to do is to place them out of doors and protect the roots from extreme cold and wet until the time comes round to have them again in the orchard house. This will be about the middle of January. As regards the orchard house itself there should be nothing pretentious or expensive about it, simply a plain span-roofed house resting on side walls 4 feet high, rising to 12 feet in the centre, and of a length and width to satisfy the requirements of the grower. No expensive fittings in the way of shelves, &c., are necessary, simply an ash-covered bottom to stand the pots upon and a single row of 4-inch hot water pipes in case of frost or extreme cold. The idea should be to produce an atmosphere as similar as possible to the climate of France, as Mr. Rivers of Sawbridgeworth so forcibly stated in his valuable essay on "Orchard-house Fruit Trees" given before the members of the Horticultural Club a short time since, and which essay will be published in due time in the Journal of the Royal Horticultural Society.

As a pleasant and interesting recreation for the business or professional man the culture of fruit trees in

pots is not to be ignored. When the trees are introduced under glass, say early in January, they require little attention or labour until they come into bloom a month or six weeks later, and the work exacted even then is of a light and pleasant nature. It only really amounts to watching the blossoms develop and helping to fertilise them by applying the pollen from the anthers to the stigma by means of a soft brush or rabbit's tail in the middle of the day when the flowers are dry. The next process is that of disbudding the shoots, leaving only sufficient to supply the necessary growth for next year's crop. The next work to engage the grower's attention will be to stop these shoots after they have formed five or six leaves by pinching out the centre. Afterwards serve all lateral growths, which will as a consequence result in the same way until growth has ceased. Another pleasant duty will be to thin the fruits to a moderate quantity: no greater mistake can be committed than to allow pot trees to carry too heavy a crop. The crowning pleasure of all will be to watch the fruits swell and grow to maturity.

Hardy fruit such as is grown in orchard houses, namely, Pears, the best dessert Apples, Plums, Apricots, Peaches, Nectarines, and Cherries, may, we know, be well grown out of doors, but there is no comparison between the quality of the two, as might easily be noticed in the exhibits at the great show of the Royal Horticultural Society at the Crystal Palace and other exhibitions. Additional details of culture the amateur will have the pleasure of giving attention to will be watering, ventilation, and the prevention or extermination of insect enemies. As regards the first little will be required until the trees come into leaf, and the tapping of the pot with a small wooden mallet will soon inform the cultivator whether the tree requires water or not. If the sound is hollow then water is required, and must be given in sufficient quantity to saturate the soil thoroughly, and alternate applications should consist of weak manure water from the stable yard or cow shed or of some well-approved artificial stimulant. As regards ventilation one should endeavour to obtain a buoyant warm atmosphere with, at the same time, a free circulation of air—a close and stagnant atmosphere is always inimical to the welfare of orchard house trees. With reference to protecting the trees from the attacks of insects one should remember that prevention is better than cure. To prevent the black or green fly from obtaining a hold when the trees come into flower and leaf fumigate with XL All in January when the buds are dormant, afterwards when the fruit is set little or no trouble should be experienced from these pests. Top-dressing the pot trees must have attention as soon as young roots appear on the surface of the soil, and this practice should be repeated from time to time until the fruits are fully developed. A good compost consists of loam and horse manure in equal proportions, with an addition of a little bone dust. The accompanying illustrations are from trees grown by Messrs. Thomas Rivers and Son of Sawbridgeworth, to whom is due the credit of originating and maintaining an interest in the culture of fruit trees in pots, not only by the splendid examples exhibited by them at the Temple and other shows all over the kingdom, but also by the practical demonstration on an extensive scale in their nurseries at Sawbridgeworth.

OWEN THOMAS.

## THE APRICOT.

WHEN one considers that the Apricot has been grown in this country for nearly four hundred

AN UNUSUALLY FINE TREE OF RIVERS' EARLY CHERRY IN THE SAWBRIDGEWORTH NURSERIES.

PEACH THOMAS RIVERS (ONE OF THE BEST OF RECENTLY INTRODUCED VARIETIES).

years, having been introduced into Britain from Italy by Wolf, gardener to King Henry VIII., in 1524, it seems incredible that the merits of the fruit, especially as an article of commerce, have not been more fully recognised and its great possibilities in this direction developed. English grown Apricots, if delivered in good condition, realise in the market at least 25 per cent. more than do the French ones, yet as an article of commercial value this fruit has received scarcely any attention. As one item that goes to make up the importance of the many minor industries associated with the land in this country, I am convinced the Apricot is deserving of more serious consideration. It must be conceded that to grow it to perfection a wall with a warm aspect is necessary, and where walls are non-existent I should certainly not recommend expensive brick ones to be built for this purpose, but what I would recommend to those who wish to make money by their gardens is to plant an Apricot tree against every available inch of warm wall surface they may have, whether the wall of the dwelling-house or the walls of surrounding buildings. As bearing on this subject I may say that it has been proved beyond doubt, and the fact is now generally admitted, that in the south of England there are miles and miles of garden walls planted with certain varieties of Pears which would succeed much better in open quarters than against warm walls. The hardiest variety of the Apricot, Breda, will succeed well as a bush or standard in sheltered positions in the open garden in the south of England,

The Apricot will succeed in any ordinary well cultivated garden soil; preference should be given to that of a holding rather than of a light nature. As all know who have had much to do with the culture of the Apricot, the greatest trouble the grower has to contend with is the unfortunate constitutional weakness it is subject to of losing many of its main branches, often in a most unaccountable way. This, unfortunately, is a trouble for which no remedy has yet been found, neither so far as I know has any satisfactory and conclusive reason been given as to the cause of the mischief. Many attribute it to injury to the bark by bruising with the hammer at nailing time, or to an accidental cut with the knife, or from severe autumn frosts.

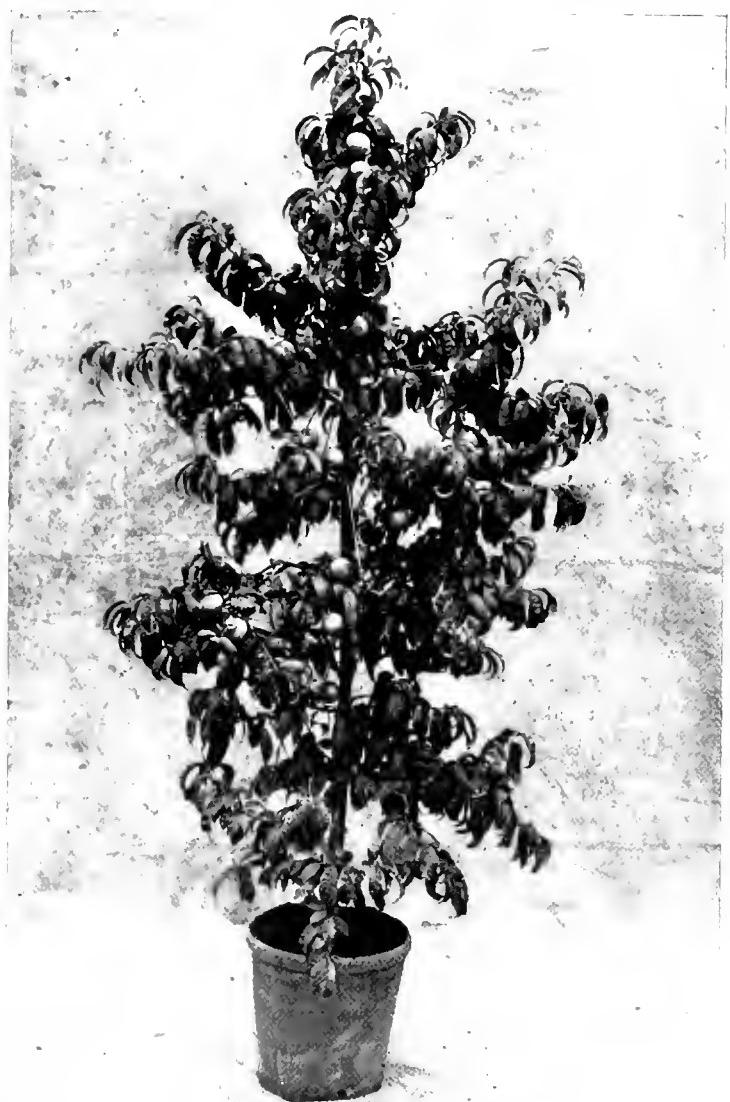

In nine cases out of

and deserves to be more extensively cultivated in this way.

The Apricot is said to be a native of Armenia, and, like the Peach, loves all the natural heat and light we can give it; therefore when possible it should be planted against walls facing south, south-east, or south-west, and even on a west wall it will prove satisfactory. On a wall with an eastern aspect it will not thrive well, there it is very liable to suffer from the effects of spring frost when in bloom. The Apricot also loves a warm soil, and it goes without saying that the border in which it is planted must be well drained, and the nature of the soil not too heavy and close. Where this is the case such material as old brick and mortar rubble, road scrapings, leaf-mould, &c., should be freely mixed with it.

It is the strongest and most gross growing branches which first succumb, and this fact, to my mind, clearly points to the remedy. Gross shoots are produced by gross roots, therefore careful root pruning must be resorted to for the first few years; indeed, until such time as the tree is able regularly to carry heavy crops of fruit, thereby effectually preventing these gross growths. If one can prevent coarse growth for four or five years, until the tree has reached a fruitful size, much will have been done to secure immunity from this trouble. The summer treatment of the Apricot does not occasion much labour, especially if disbudding has been carefully attended to, for when heavily cropped the growth of foliage is not great, and what we have to do is to stop the lateral shoots at the sixth or seventh leaf and to tie in or nail the terminal shoots. These, so long as there is any portion of wall to furnish, should be laid in without any shortening whatever. The Apricot is the earliest of our hardy fruit trees to blossom, the flowers usually opening in March or even the end of February. It is very necessary therefore to protect them if one wishes to secure a full crop of fruit. Where the usual coping of board or glass exists, with tiffany blinds to roll down in front of the trees, no better precaution could be had. In the absence of this arrangement, however, fish nets if suspended, of double or treble thickness, in front of the trees will answer well.

If fine well developed fruit for dessert is the object thinning must be carried out with a free hand,

NECTARINE VICTORIA (ONE OF THE BEST LATE VARIETIES) AS A POT TREE.

for the Apricot as a rule sets its fruit freely. A healthy Apricot tree is as capable of bearing a heavy crop of fruit without injury as any hardy fruit tree we have. Thinning the fruit should be performed at two or three different times; the first ones should be removed soon after they are set, then simply taking off the smallest. Go over the trees again when the fruit has reached the size of Hazel Nuts and in about a fortnight's time they should be finally thinned. The quantity left for each tree to carry must be a matter for the experience of the cultivator to decide.

A. P. H.

### CURIOS CYCLAMEN FLOWER.

NEARLY all kinds of flowers at times show a tendency to "sport," and Cyclamens are no exception to the rule, but this tendency is not so common with them as it is with many other flowers. Not having seen the flower of which a figure is given I cannot say positively what has taken place, but it appears to me that it is an example of what botanists call "petalody of the stamens," that is to say, the stamens have become or tried to become petals; this is the case with all truly double blossoms, the stamens have turned into petals. In the present instance, if my suggestion is the right one, the abnormal stamens have assumed the form of petals of a Japanese Chrysanthemum, twisted round the base of the normal petals. This is a very curious monstrosity, but one that it would not be desirable to perpetuate.

G. S. S.

### CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### THE NATIONAL CHRYSANTHEMUM SOCIETY.

[To THE EDITOR OF "THE GARDEN."]

SIR,—I have just been looking through the schedule of prizes of the National Chrysanthemum Society for 1902, and I find that five members of the executive committee are the paid judges at the exhibitions of the society; and of this number three of them are the principal officers of the society—men who as members of the show committee are supposed to be intimate with the names of the exhibitors and the classes in which they exhibit; and as members of the show committee they, I imagine, have the direction of the placing of the various exhibits. More than this—I also perceive that the three principal officers who are judges are also members of the arbitration committee, whose duty it is to deal with any protest as to the awards of the judges, so they may have to consider protests made in reference to their own awards. By referring to the schedule of prizes for 1901 I find that eight members of the committee were judges in that year, so there is reason to hope that the proper but unsuccessful attempt made at the last general meeting to so alter the rule of the society as to the election of judges so as to disqualify members of the committee from acting in that capacity—an alteration which the *Gardeners' Chronicle* states to be both just and proper—has had some good effect, as seen in the reduction of the number of judges in the present year taken from the committee.

The practice of selecting to make awards those who administer the affairs of the society is so opposed to universal practice and liable to be adversely criticised that I am astonished so influential a society, which I have heard claims to be the foremost special floricultural society in the kingdom, sets such a bad example to its many affiliated

societies. If all the men capable of judging Chrysanthemums, &c., were included in the committee there would be some excuse for this state of affairs. So far from this, there are about the country many men who in addition to possessing the highest qualifications as judges, are also warm supporters of the society, but these receive no invitation though in not a few cases their services are in demand as judges elsewhere.

If anyone will turn to the back page of the third leaf of the schedule of prizes, they will see set forth the composition of the schedule revision sub-committee who have the nomination of the judges; four of the members of that committee are judges and so nominate themselves. If any six members of that committee will agree among themselves to nominate and vote for each other and no other candidate, taking care to be present at the meeting when the nominations are made, they are certain to be elected, as I am informed that the executive committee who make the final selection invariably accept these self-made nominations. The sooner the members remove this state of things the better

successful with ordinary care and intelligence perhaps some grower will give me a list of about twelve good dessert sorts of Plums suitable for pot culture, and about six sorts of Cherries, with details of management, including top-dressing, repotting, &c. J. E.

[The subject of our correspondent's enquiry is one of great and recurring interest to fruit growers. The desire to grow a few fruit trees in pots in vineeries and other houses occupied by permanent Vines, Peach trees, &c., has been a source of perplexity to many minds for years. The question asked by our correspondent, namely, "Is it possible to grow successfully stone fruits in pots in a vineery started into growth on the 1st of February?" may, we think, be answered in more ways than one, and the answer will depend very much what is meant by "successfully." If the highest success attainable under the best and most favourable conditions of growth is meant, we say at once, and emphatically, that it is not possible. But if the grower should be satisfied with moderate success as regards yield of crop and quality of fruit in, say, three seasons out of five,

he may indulge in the hobby with a prospect of this qualified success being obtained. In such a case his trees should be placed in the vineery the first week in January, the house being still kept cool and airy. The atmosphere of the vineery, although cool, would be warmer than the air outside, and would prepare the trees to expand their bloom with the little extra heat applied on the 1st of February. Once the trees are in bloom, air more or less must be admitted day and night. To prevent the undue lowering of the temperature to the detriment of the Vines starting into growth a little heat in the pipes may be provided during cold and frosty weather. The temperature best calculated to suit the stone fruit trees all through the growing season will be a moderately low one, always with a slight current of air circulating through the house, a lower and a more airy temperature than that which would suit the Vine best. Therefore in growing the two together it must always be a question of compromise between the two throughout the season.

We would suggest that in dealing with the subject a far more satisfactory result would be arrived at by dividing the house into two (having a partition between), planting the Vines in one division at the right distance apart, reserving the second division of the house for the fruit trees in pots, where the proper conditions necessary to successful growth could be provided and complete success achieved both with Vines and the pot trees. Supposing the grower is now about to buy his trees with the intention of having ripe Cherries early in May until well into June, and Plums from the first week in June until they are ripe out of doors, he should make sure that the trees are well furnished with fruit-buds and that they were repotted about the end of September in pots not too large. The trees are best left out of doors until introduced into the house about the middle of January; provided the pots are protected from frost and from too much moisture at the root. Annual repotting in the autumn is imperative if satisfactory crops are to be obtained. The subject is a large one—far too large to enter fully in answer to a question. One of the chief conditions necessary to success in the growth of the Plum and the Cherry in pots is to provide a fairly cool atmosphere, with a circulation of air day and night until the trees are well set with fruit, using as little fire-heat as possible, but this must be available when wanted in case of a spell of frosty and cold weather. After a good set of fruit is secured a more generous temperature may be given, but the trees on no account should be hard forced at any time. Disbudding must be duly attended to; so also must the top-dressing of the roots with rich soil, consisting of half loam and fresh horse manure, with a sprinkling of bone-meal. The young roots will take to this top-dressing with great avidity, and it should be

A CURIOUS CYCLAMEN FLOWER.

for the society, which just now that it has to seek a new home needs all the support it can obtain.

A COUNTRY MEMBER.

### PLUMS AND CHERRIES.

[To THE EDITOR OF "THE GARDEN."]

SIR,—I would like to ask those readers of THE GARDEN who have had some practical experience in the following subjects: Is it possible to grow successfully stone fruit trees in pots in a vineery, started into growth on the 1st of February? The house is a span about 20 feet wide. The Vines could be trained 10 feet apart vertically. This distance apart would no doubt give plenty of light for the fruit growing underneath, but the temperature to suit all subjects through their various stages of growth is what I am in doubt about. Plums and Cherries are the fruits we would like to grow if they could be grown satisfactorily under the above conditions, but we would not attempt it if there were any doubts about the plan succeeding. If the scheme is likely to be

repeated over and over again at intervals until the top-dressing is built up several inches above the rims of the pots. Rain-water should be used for watering and syringing when available, especially for syringing purposes, as it leaves no sediment behind on the fruit. Watering must receive great care at all times; give an abundance during hot weather whilst the trees are making their growth and the fruit swelling, and twice a week at least use diluted manure water. As soon as the fruits show signs of ripening plenty of air must be admitted, as high flavour and finish cannot be had without. Plums should be left on the trees until well ripe, and they should never be picked immediately after watering or the flavour will be insipid. They should be separated from the branch by a pair of scissors, and not plucked off. Insect pests must be guarded against at all times by periodical fumigation with XL All insecticide. Soon after the trees have ripened their crop they should be removed out of doors and plunged in leaves or ashes, potted at the end of September, and introduced into the house for forcing again in June.

The following varieties of Plums, arranged in the order of ripening, are amongst the best for dessert, and succeed well under pot culture: July Green Gage, Denniston's Superb Gage, Green Gage, Oullin's Golden Gage, Transparent Gage (new early), Purple Gage, Kirke's Purple, Guthrie's Late Green Gage, Coe's Golden Drop, Jefferson's, President (Rivers'), and Rivers' Late Orange.

Cherries, in order of ripening: Guigne d'Annonay, Belle d'Orléans, Bigarreau Jaboulay, Frogmore Bigarreau, May Duke, Belle de Choisy, Elton Heart, Royal Duke, Governor Wood, Waterloo Heart, Bigarreau Napoleon, Bigarreau Monstrous, Florence, and Black Tartarian.—ED.]

## THE ROYAL HORTICULTURAL SOCIETY AND ITS CONFERENCES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Permit me to answer the criticism of Mr. Barr *re* the Royal Horticultural Society and its conferences (page 308). It would be impossible to frame a five-year schedule, and the Lily conference was a huge success. Many of the most famous Lily authorities in the world contributed, Dr. Henry among the number, and the volume of the Journal containing the report and the papers read is surely an answer to Mr. Barr's remarks. The Royal Horticultural Society is to-day in a proud position, and we are glad. It is a source of great satisfaction to me that THE GARDEN, a journal I now take keen delight and interest in, supports the council of the Royal Horticultural Society in all its good works. I am glad THE GARDEN is still quietly working for a proper sphere of action with regard to adequate trial grounds, and I hope its efforts will not be unavailing. F. R. H. S.

[We thank our correspondent for his kind remarks about THE GARDEN.—ED.]

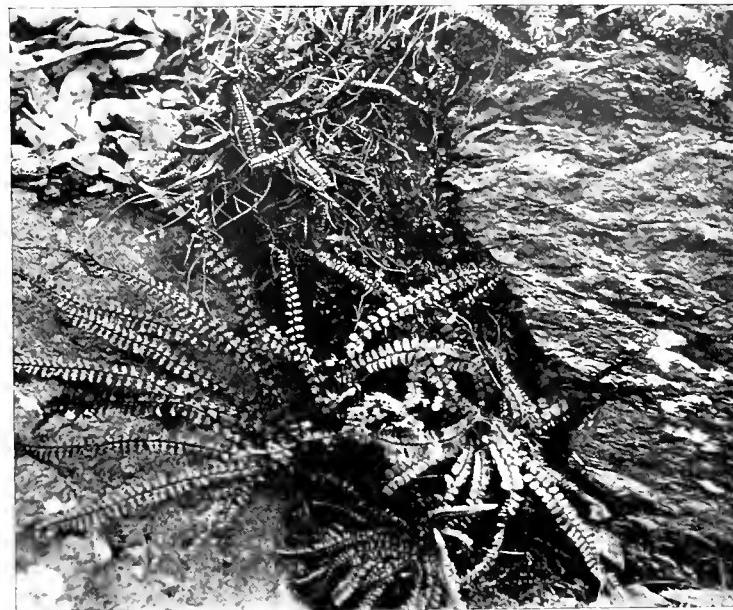

## THE FERN GARDEN.

### THE MAIDEN-HAIR SPLEENWORT.

(*ASPLENIUM TRICHOMANES*.)

**U**NDOUBTEDLY this little Fern is one of the prettiest of our wall Ferns, and in many places where the Fern vandal is discouraged it may be found draping old walls with its pretty rosettes, or peeping from the chinks of wayside stone dykes and hedge banks. Its popular title of Maiden-hair is due to the intensely black and shining slender midribs of the fronds, but it has no connexion with the Maiden-hair family proper, the Adiantums; like most of their relatives, of which they have many, the Asplenias or Spleenworts constitute a large genus. It is evergreen and loves a rocky situation; it is also a lover of dry positions, and consequently does not readily lend itself to culture under the moister

environments preferred by, and hence afforded to, most Ferns which are grown. The fronds object to being wetted much, and are apt in such case to turn black, with a kind of rot, if kept under close conditions, which hinder evaporation. The best plan, therefore, is to give it a north aspect in a wall chink, or to insert it between pieces of stone or brick arranged on a steep slope, and then to cover it with a bell-glass which freely admits air beneath it. The finest specimens we have seen in cultivation were grown in this way. Curiously enough though the family of Spleenworts is a large one, and peculiar in the great range of size which it embraces (*A. septentrionale*, for instance resembling a small tuft of grass, while *A. Nidus*, the Bird's-nest Fern, may have huge fronds 5 feet high and 1 foot across), there is very little tendency to sport among the great majority of the component species. One little Maiden-hair Spleenwort, on the other hand, has broken through the family tradition of constancy, and given quite a number of pretty varieties. *A. T. mersunum*, for instance, has been found repeatedly in a wild state, and represents precisely the same sport in the Spleenworts as *Polypodium cambricum* or the plumose and so-called Welsh Polypody does in that family. The little side divisions of the species are normally oval and smooth edged, but in incisions they are very much larger and beautifully cut into sharply pointed segments. Crested forms have also been found over and over again, in which the end of the frond is branched out into ornate little tassels. *A. T. cristatum* and *A. T. hamo-cristatum*. Others again, like *A. T. Mouleii* and *A. T. Harrovii*, have the side divisions extra small and the edges deeply crenate or bluntly toothed. A friend of the writer, Mr. C. B. Green, of Acton, recently found examples of this in Devonshire, and being the happy possessor of a camera, he seized the rare opportunity thus afforded of photographing a wild Fern sport *in situ*, as shown in our reproduction. The photograph is the more interesting, as it shows how varieties originate in conjunction with the common type, which is also shown in the picture. Besides the main plant of the "find" we may detect a seedling of it in the top right hand corner, and in fact there were several others close by. The spores of *A. Trichomanes* and its varieties are very easily raised in the usual way, and the plants, as a rule, come true. The incisum group, however, are invariably barren, and consequently rare, as they can only be propagated by division. A group of the best types grown as suggested forms an extremely pretty picture. We have grown good specimens also in a Wardian case by giving plenty of light and taking particular care only to water the soil and not the fronds. Treated thus judiciously the small size of the species renders it peculiarly fitted for such culture. The sportive capacity of *A. Trichomanes*, coupled with the established fact that it is possible to induce variation in more or less allied species by means of hybridisation, opens up a fine field for Fern hybridisers. As we have said the genus varies greatly in size and also in form, some species being delicately cut, as in the *Asplenium bulbiferum* group, and some not cut at all, as in the Bird's-nest Fern, which rather resembles a huge Hart's-tongue, but in so doing by no means forfeits its claim to

ASPLENIUM TRICHOMANES VAR. CRENATUM GROWING WILD.

Spleenwort kinship, as the Hart's-tongue itself is undoubtedly closely allied. Discrepancy in size, however, forms no bar at all to Fern crossing, hence the giant and the pygmy species may quite possibly mate, and this possibility involves a chance of introducing differences of form and greater delicacy of cutting and capacity for forming tassels into such species as have hitherto declined to "sport" spontaneously. Sow the spores of the two species together, the plain fronded exotic and the ornate sport of the native *A. Trichomanes*, and while the grower cannot lose, since any way he gets his crop of both, he may gain by finding some day amongst his sportlings a *rara avis* in the shape of a brilliant combination, plus probably a harder type of the exotic form. Such things have been done in another family, the Polypodies—*P. Schneiderii* to wit—and therefore may be done again. In that now well-known Fern, our comparatively little *P. vulgare*, in its beautiful varietal finely cut and eccentric Cornubiense type, has infused its full character into the huge growing exotic *P. aureum*, while hardening it sufficiently to stand some degrees of frost, as our own experience demonstrates.

CHAS. T. DRUERY, F.L.S., V.M.H.

## GARDENING OF THE WEEK.

### THE FRUIT GARDEN.

PLANTING FRUIT TREES.

**R**ECENTLY instructions were given for planting some varieties of hardy bush fruits, and many of the remarks then made are applicable to the subjects now treated upon. Directions have also been given for preparing the land. In the case of Apples, Pears, Plums, and similar large growing trees, however, it will be advisable to secure them to reliable stakes as soon as they are planted, and in carrying this out their bark should be protected where it comes in contact with the stakes with pieces of old indiarubber hose or hay bands. The stems of trees that are planted against walls should be kept at least 4 inches clear, so that adequate space for them to swell is afforded, and they should be but loosely secured to the wall until the soil has settled. Excellent varieties of all kinds of fruit suitable for special purposes are now very plentiful, but space prohibits lists of them being enumerated here.

STANDARD APPLES, PEARS, &c.  
Sheltered sites should be chosen for these

sufficiently far away from forest trees to prevent injury from their shade or roots. The trees should be worked upon free stocks and be planted at least 24 feet apart each way. In planting varieties that yield very large fruits select positions for them that are the most sheltered, otherwise much of their best fruit will probably be blown down and spoilt, and in grass orchards each tree should be protected from cattle and rabbits and have a space of several feet in diameter cultivated around it. Standard Plums should possess clean stems 6 feet in height, and strong growing kinds be planted about 20 feet asunder, while moderate growers should be placed from 15 feet to 18 feet apart.

#### PYRAMID AND BUSH TREES.

Apples, Pears, Plums, and compact growing varieties of Cherries should in an ordinary way be planted 12 feet apart each way, although where great variety is wanted, compared with the space at command, they may be confined to 9 feet, while strong growing Cherries with spreading habit should be allowed 15 feet. Pyramids and bushes are much more suitable trees to plant, at least in gardens, than are standards, but in any position they are best grown upon cultivated land, and for this description of tree the Apple should be worked upon the Paradise and the Pear upon the Quince stock, this being all the more important if the soil is deep and strong.

#### CORDON TREES.

This mode of training has some decided advantages, amongst them being early fertility and that of its being possible, by planting trees of this kind, to secure a greater variety of fruit from a given space than can be obtained from any other sort of tree. The Pear is particularly amenable to this mode of culture, either when grown upon walls or trellises. Single cordons should be planted from 15 inches to 18 inches apart, the trees being worked upon the Paradise stock.

T. COOMBER.

*The Hendre Gardens, Monmouth.*

#### INDOOR GARDEN.

##### FORCING SHRUBS.

THOSE who contemplate purchasing from the nurseries should do so without further delay. For early forcing plants that have been grown in pots during summer are preferable, and are best adapted for this work. It is a good plan to place the plants on arrival in damp leaf-soil or cocoanut fibre, watering them well. Let them remain for a few days previous to potting; after potting they should be watered and plunged in cocoanut fibre, which will keep the roots moist. Protect them from frost until taken indoors. These plants well repay careful attention, and should be given pots of a size that will admit of about an inch of soil being well pressed in around the root mass. Liberal drainage and good rich fibrous loam, peat, and sand should be used. Those delivered in pots should have their drainage and roots examined.

##### LILACS

are indispensable for forcing, and are always admired when in flower. Imported plants from the continent are invariably the best for early forcing. A moist temperature of about 55° will be sufficient at first. When placed in too high a temperature growth is induced to start, and the flowers often remain dormant and die away instead of opening. Marie Legraye is the best early white. Charles X. is a fine dark free-flowering variety. Gloire de Lorraine is the best red one. President Grévy, Mme. Lemoine, and Michael Buckner are some of the best sorts.

##### MAGNOLIAS

make excellent plants for pots, but must not be hard forced. M. Lennei is a deep red, M. Yulan is a good pure white, M. Soulangiana is a white variety tinged with pink. The Guelde Rose (*Viburnum Opulus*) and V. plicatum are useful for forcing. Dentzia gracilis, Staphylea colchica, and Kalmias with their lovely red and pink flowers must not be overlooked. Prunus, Genistas, and Almonds are shrubs which lend themselves to

forcing. Rhododendrons, Choisya ternata, and shrubby Spiraeas, such as Louis van Houtte and punifolia, must also be included. Wistarias, Laburnums, and many other things might be mentioned. Many of the above will come into flower without being subjected to a high temperature, and the flowers will last for a much longer time, and are of a much better colour when not hard forced.

#### AZALEAS.

These are among the most important of hard-wooded plants for cut flowers or as decorative plants for the greenhouse. Where a large quantity of cut flowers is desired early, old plants are the best for this work. Such varieties as Deutsche Perle and Fielder's White, if the growth has been well ripened early, will come into flower at this season with very little forcing. Azaleas are very liable to the attack of thrips and red spider. Syringing the plants freely—on no account letting them become dry at the roots—will keep these pests at bay. Azalea mollis and Ghent varieties should be largely grown for decoration and cutting purposes. When not hard forced the flowers will last well in water.

Slough.

JOHN FLEMING.

#### THE FLOWER GARDEN.

If one desires that portion of the flower garden adjacent to the dwelling-house to be interesting and pleasant during the winter months attention to covering the bare surfaces may be commenced as soon as the autumn flowers are over, but this year beds and borders of herbaceous perennial and annual plants have remained exceptionally long in beauty, and while they remain thus it would be simply folly to interfere with the beds unless it is just occasionally going over them to remove unsightly plants. Once, however, frost and wet have destroyed them preparation should be made to enhance their appearance, and for this purpose a good collection of shrubs of various shades and hues should be at hand. Herbaceous plants, perennial and biennial, with fine foliage may with advantage be employed, Aralias, Ajugas, Stachys, Sempervivums, Sedums, Thymes, Wallflowers, and large flowered Vincas, with groups of bulbs amongst them, would make an effective arrangement to interest and please throughout the winter and prevent these particular beds from becoming eyesores. Bulb planting should be finished as soon as possible. All kinds of plants might now be relegated to their winter quarters in the propagating department, where the more delicate sorts should be arranged by themselves, while those requiring cooler treatment should be kept together.

The present is a good time to make in the reserve garden a bed of Lily of the Valley. In May and June such a bed is invaluable for cutting from, as these beautiful flowers are always in demand. Partial shade and plenty of moisture are essential to their successful culture, while in preparing the ground quantities of leaf-mould and rotten cow manure should be used. In planting the crowns they should be placed 2 inches apart, when they will thrive for five or six years without any need of being removed.

St. Fagans.

HUGH A. PETTIGREW.

#### THE KITCHEN GARDEN.

##### TRENCHING.

I do not advise trenching wet, heavy soils before spring, as I have proved that it is far better done at that season, but on light, porous ground no time should be lost in pushing this forward. Every vacant plot should if possible be so treated before the end of the year. Though it is not possible in all gardens owing to want of labour, every endeavour should be made to take advantage of deep cultivation as much as possible, for by so doing new life is put into old gardens and the return is great compared with that from land simply dug over. In case of heavy soils where it is not possible to leave all till early spring owing to pressure of work at that season, it will be far better to do it now than not at all. Work in plenty of long stable litter at the bottom,

and, indeed, refuse of almost any kind, such as leaves, sweepings from the walks, burnt refuse, and so forth. When the soil is deficient in lime strew a good coating over the surface after the work is completed. Mushrooms are in most places highly esteemed all through the year, and advantage should be taken to make up a bed in every available place where they are likely to grow and plenty of material is at hand. Beds may be made up in the open at any season of the year. When properly done and a sufficient bulk of suitable material is placed firmly together, make it up ridge shape, and well cover with long stable litter. Good results may be looked for sooner or later, even during the depth of winter. Beds which are now bearing in the Mushroom house will be much improved by giving a good soaking of farmyard manure water when dry, which should be warmed before using. Avoid too much fire-heat or the yield will be short and the quality poor. What promotes the good growth of Mushrooms during the winter months is the slight heat which arises from newly-formed beds.

Seakale is very late ripening up its crowns this season, consequently it will not answer to forcing quite so well as in some years, but every endeavour should be made to push it along as speedily as possible. Introduce good batches weekly, giving it the warmest end of the Mushroom house or some other convenient place.

#### CHICORY.

generally much appreciated for winter salads, should also be brought on in heat, keeping it quite dark. The roots are much better left in the ground and taken up as required, unless the weather threatens to be very severe, when in this case some may be taken up and stored away in ashes.

Dandelion should be treated in the same way as Chicory.

#### ENDIVE AND LETTUCE.

Late plantings of these have made good growth, and no time should be lost in placing the plants in cold frames, late orchard houses, or in some position where protection can be given.

#### CHERVIL.

Lift and plant in boxes small quantities at a time and store in cool houses or frames.

#### MUSTARD AND CRESS.

should be sown in boxes and placed under glass weekly.

E. BECKETT.

*Aldenham House Gardens, Elstree, Herts.*

#### ORCHIDS.

##### ORCHIDS IN BLOOM.

At no season of the year are Orchid flowers more appreciated than at present and during the winter months, and with the numerous species and varieties now available there is little difficulty in maintaining a show throughout the year. Many of the hybrids bloom during the autumn and winter months and tend to brighten our houses at this season. Considering the time, care, and expense required to bring such plants to perfection, it is remarkable what lovely hybrids can be bought at a very low figure. The freedom with which they grow and the way they increase gives lovers of Orchids who intend forming good collections every encouragement to procure all the hybrids as they appear.

In the Cattleya houses the following are a few of the hybrids now in bloom: Cattleya Lord Rothschild (*C. gaskelliana* × *C. dowiana* var. *aurea*), Lælio-Cattleya Lady Rothschild (*L. Perrinii* × *C. Warscewiczii*), Cattleya Mrs. J. W. Whiteley (*C. bowringiana* × *hardiana* var.), Cattleya Portia (*C. bowringiana* × *C. labiata*), Lælio-Cattleya Decia (*L. Perrinii* × *C. dowiana* var. *aurea*), Cattleya Mantinii (*C. bowringiana* × *C. dowiana* var. *aurea*), Lælio-Cattleya Isis (*L. pumila* × *C. Marstersoniae*), and Lælio-Cattleya statheriana (*C. labiata* × *L. Perrinii*). The most conspicuous species now in flower is the beautiful Cattleya labiata, accompanied by *C. bowringiana*, the two making a good show. While the plants are in bloom the atmosphere must be kept drier than usual or the flowers are quickly disfigured by

spot and do not last their usual time. After the flowers have been taken from the plants, the bases of the sheath and flower-stem upon some plants of *Cattleya labiata* remain damp and a downward decay takes place; which, if not noticed in time, will inevitably ruin the bulbs. When a sheath is not dry and crisp and ripened off in a natural manner, it should be entirely removed and the flower-stem cut clean off. Should there be any sign of decay, scrape away the base of the flower-stem level or a little into the apex of the bulb, and put in a pinch of flowers of sulphur. This quickly dries up the affected part and prevents the loss of the bulb.

In the warm houses *Dendrobium Phalaenopsis*, *D. bigibbum*, and *D. statterianum* give us a good show of bloom, also many of the *Selenipediums* and numerous species and hybrids of *Cypripediums*. Though there are many fine hybrids of the latter, there are few that surpass in beauty the lovely old *C. spicerianum*, which at this season is one of the most useful. The cooler section of *Cypripediums*, such as *C. leeanum*, *C. lathamianum*, *C. Sallieri hyeanum*, *C. venustum*, *C. insigne* and its numerous varieties, *C. i. Sanderae* being the most beautiful. Other species and numerous hybrids will afford us a fine show of bloom for many years to come.

In the cool and cool intermediate houses numerous species and varieties largely contribute to the supply of bloom, *Odontoglossum crispum* being well represented, likewise *O. andersonianum*, *O. ruckerianum*, *O. madrense*, *O. grande*, *O. loochristiense*, *O. Hallio-crispum*, *O. Rossii*, *O. crocidipteron*, *O. Uro-Skinneri*, *Maxillaria venusta*, *Miltonia vexillaria leopoldiana*, *Sophronitis grandiflora*, *Lelia pumila*, also *Oncidium varicosum*, *O. praetextum*, *O. Forbesii*, *O. tigrinum*, *O. cheirophorum*, *O. ornithorhynchum* and its variety *album*, *O. Mantinii*, and *O. incurvum*. The flower-spikes should not remain long on the plants after the last blooms have expanded, especially those of *O. varicosum*. Many little curiosities are in bloom. If not showy, they are very interesting.

F. W. THURGOOD.

Rosslyn Gardens, Stamford Hill, N.

## MISCELLANEOUS.

**Chrysanthemums at Redhill.**—Mr. William Wells, of the Earlswood Nurseries, Redhill, has, of all the Chrysanthemum specialists, rendered very exceptional service by the introduction of the Pockett seedlings into this country, many of which are of a high order of merit. The flower-loving public had just begun to settle down, as it has on more than one occasion before, to expect that the future novelties were destined to be imported from one source only, a source which had certainly produced many brilliant examples of the raisers' cultural skill, but which after a lapse of several years' unqualified success had begun to show signs of deterioration. American novelties have for some reason or other long since ceased to figure in the yearly trade displays. Continentals of the past two or three years have unquestionably been of a lower order of merit than before, and therefore it is not surprising that the Australian seedlings should have received a larger share of popular support than might have been meted out to them had the quality of the others been maintained. We always begin our round of the trade displays by a visit to Earlswood. Blooms that are produced early in the season and in such fine condition as we usually see them there are always bright and clean. Being away from the metropolis and in the full light of the country we find the colouring more vivid and more in accordance with the raisers' descriptions than when the same varieties are produced close to town. There are several glass structures in which Mr. Wells' Chrysanthemums are housed, but the large show house, containing the pick of the collection, holds about 2,000 plants in pots, all of which were at the time of our visit coming on with great promise, although perhaps a little behind owing to the vagaries of the season. A grand lot of Mrs.

T. W. Pockett must first be noticed: the blooms are really noble and imposing, and the colour a pure deep canary-yellow. Not very much unlike it at a distance is Mrs. Harry Emmerton, an immense Japanese, with long drooping florets, forming a deeply built flower, and of a similar shade of colour. General Hutton is another Japanese floral colossus, but of a bronzy yellow shade. W. R. Church is of a deep rich rosy crimson colour, with reverse of bronze, a massive flower of most attractive appearance. Mrs. Alex. McKinley, like the preceding, is an Australian, and a very effective one too, the colour being a fine golden-yellow streaked with terra-cotta. Cheltoni, a pure pale yellow sport from Nelly Pockett, is identical in all other respects with its parent. From various sources come such striking novelties as Millicent Richardson, a fine amaranth; Godfrey's Masterpiece, Lord Ludlow, Mrs. White Popham, Nelly Towers, a charming shade of rosy mauve with silvery reverse; Bessie Godfrey, Mrs. George Mileham, and many others that were seen for the first time last year or the year before and still maintain their reputation. There are several new additions this season in really rich deep crimsons, one of the finest perhaps being S. T. Wright, a Japanese with pointed florets, the colour being a very deep velvety crimson, showing a metallic reflection, the reverse golden-bronze; Lord Alverstone is another, it has rather flat florets, but the colour is singularly rich and effective even for a crimson. Mr. Wells is of opinion that some of the continentals will this year be improvements upon those of the past two or three seasons. We noticed some excellent blooms of Mme. Paolo Radaelli, a variety already well known, but still sufficiently recent to be regarded almost as a novelty, and one of the best of Calvat's recent seedlings. From the same raiser comes La Fusion, a large globular Japanese with intermingling and incurving florets, colour pure white tinted flesh. His older Louise and Mme. Gustave Henry both continue to be good and useful varieties, and Calvat's Sun, a fine deep golden-yellow Japanese, first shown at the Great Paris International Exhibition of 1900, is undoubtedly a novelty of conspicuous merit. This year's seedlings include Mme. Waldeck Rousseau, a monster bloom of enormous size, having florets that are deeply grooved, pointed at the lips, and building up to a form of great depth and solidity. The colour, a deep velvety crimson-red, with a straw yellow reverse, makes a striking effect, and we should think there is a future in store for this, especially on the show-boards. Mme. L. Cheveaut is a charming shade of rosy flesh pink something paler but not altogether unlike Mrs. Coombes. In Calvat's set we also noticed Louis Levéque, a very large Japanese of a velvety plum-coloured crimson; Melina, Souvenir du Ministre P. Legrand, and Electreux we must see again before anything can be said of them.

**Southwark Park.**—Among the various Metropolitan displays of Chrysanthemums the collection at Southwark Park is always of peculiar interest, by reason of the disadvantages that surround it. Situated in a densely-populated neighbourhood, and surrounded on every hand by dingy streets of houses and factories, it is surprising what a remarkably good display of the popular autumn flower is annually made, to the evident delight of many of the residents who otherwise would have but little opportunity of gratifying any horticultural tendency they might have. The nearest approach to the T-shaped greenhouse, in which the collection is very tastefully arranged, is that in the Gomme Road, and a few paces to the right brings the visitor in full view of the house. The collection is an admirable example of gratifying every taste, for it contains varieties of every type and section. Some of the old-fashioned incurves are in good form, and of these white Beverley, C. H. Curtis, Mr. Bunn, Prince of Wales, various members of the Queen family, the highly-coloured Baron Hirsch, and Jeanne d'Arc need no description. The large Anemone-flowered section is also represented in fair proportions, and is useful by way of varying the effect. The richly-coloured Descartes has no rival in such mixed groups as we see in the London parks, and is always well done. Junon,

a pale lilac manne, Mrs. P. R. Dunn, a large white self, Delaware, M. Chas. Lehocqz, and Mrs. Judge Benedict are other instances in the section named. Here, as elsewhere, the weird fantastic Japanese predominate. Raisers from all parts of the world contribute their quota towards charming the eye of the local connoisseur, who, from remarks that were audibly made in our presence, is quite competent to pass judgment on some of the more recently introduced kinds. From America there are the bright rosy pink Wm. Tricker, Eda Prass, pale pearly pink; Duke of Wellington, a fine solid golden bronze incurving Japanese; Good Gracious, always curious in form; International, J. H. Runchman, a deep globular golden-yellow; Simplicity, Col. W. B. Smith, and others which we cannot specifically mention. Among the French varieties those of Calvat must still take precedence. In whites the Mme. Gustave Henry is wonderfully fine. Various shades of pale pinks and mauves include noble blooms of N. C. S. Jubilee, Mrs. C. Harman Payne, Louise, a grand incurving Japanese of some years standing; Mme. C. Terrier, Mme. Marin Ricoud, Mme. Ed. Rey, and L'ami Etienne, the last two being especially valuable for their size and earliness. Others from the same raiser are M. Pankoucke, Boule d'Or, Soleil d'Octobre, Le Grand Dragon, Amiral Avellan, and M. Fatzier, which are either yellow or bronze, while purple and crimsons include Commandant Blussel and M. George Birou, both extremely useful sorts. There is a good mingling of excellent sorts from other Continental growers. We need only name Duke of Berwick, Mme. Gab. Debrie, M. Louis Rémy, La Triomphante, and Ed. Audiguier to remind us that Delaux, Nonin, de Reydelles, and others have not been entirely supplanted in our general collections by their great rival. Hairy varieties, which once formed a prominent feature in Southwark Park, appear to have declined in popularity here as elsewhere. We only observed Louis Boehmer, Beauty of Truro, and Enfant des deux Mondes belonging to that section.

**Chrysanthemums at the Monkham's Nursery, Woodford.**—The neighbourhood of Woodford in recent years has developed into a well-known centre of Chrysanthemum growing interest, several of our more prominent cultivators hailing from this part of Essex. No one has made greater strides than Mr. R. C. Pulling, his magnificent exhibits at the Royal Aquarium, Westminster, and also at Edinburgh's grand autumn display gaining for him enviable notoriety. This season he has excelled his display of large and handsome exhibition blooms, outrivalling any of his previous efforts. No pains have been spared to achieve success, and on the occasion of our visit evidence was not wanting of the pains taken to produce good blooms. Phenomenal representatives of the majority of the best Japanese sorts in cultivation were to be seen, and not only were they large, both in depth and breadth, but they were also of good form and remarkable for their rich and bright colours. Immense blooms of the massive-looking Japanese incurved W. R. Church confronted one on entering the spacious glass structure in which the exhibition plants are housed. This is a grand rich crimson flower with a rich bronze reverse to the broad, incurving petals of considerable substance. The beautiful English-raised seedling Mrs. G. Mileham was in grand form and condition. The lovely silvery mauve-pink is very pleasing, and the form is all that one could desire. The silvery white reverse enhances the value of the blooms, which are deep in build. The Australian novelty, Mrs. T. W. Pockett, is a large flower of neat and even form, and of great depth. Deep canary-yellow is hardly accurate, a deeper shade of yellow being a better description altogether. This variety appears to be very reliable, coming good on all buds. Matthew Smith is another very large Japanese novelty, tinted reddish crimson on a golden-yellow ground. There will be many blooms of exceptional quality shown. Mme. Carnot, white; Mrs. W. Mease, primrose; and G. J. Warren, rich yellow, make an admirable trio. Blooms of Mrs. Barklay have probably never

been seen in finer condition. There was an immense number of heavy blooms, with petals of enormous breadth and substance, and the rosy mauve inside colouring and silvery white reverse have rarely if ever been equalled. Ethel Fitzroy, one of Mr. A. Weeks' superb seedlings, promises to be of great value to exhibitors. The colour is orange-amber, and the flowers are large and handsome. It is also a plant of easy culture. A refined bloom is Mrs. E. Hummel, with long petals, building a curious and prettily-shaped Japanese incurved. The colour is pinky white, shaded yellow. This is another of Mr. Weeks' seedlings. A lovely flower is Miss Evelyn Douglas, and quite unique in its build and character. The petals are not over long, but they are very numerous, and make a flower of great depth and solidity. The colour is one of its chief charms, this being a pleasing shade of rosy mauve, slightly tinted cerise. A rich golden-yellow flower is Scottish Chief, and a superb specimen of this deep flower of good form was conspicuous. Mr. Pulling has been singularly successful with Le Grand Dragon this season. There were blooms of great breadth and good depth, and in accomplishing this the form was all that one could desire in stiff competition. The colour this season is a grand orange-yellow, and is very effective. That grand plant of Australian origin, J. R. Upton, was bearing very large and deep blooms of a beautiful shade of yellow. Sensation, the flower which was so much admired among last season's novelties, is finishing in grand form. The blooms are of great breadth and correspondingly deep. Deep rich yellow, shaded bronzy crimson, aptly describes its colour; it will be invaluable to exhibitors. The soft yellow or primrose colour of Mme. Von André, the pretty sport from Mutual Friend, is another of the good things this season. There were, of course, many others which space does not permit us to mention. Incurved Anemones and Pompons were each represented in good form and by reliable kinds. In all some 12,000 plants are grown here, 900 of which are reserved for exhibition purposes.

**Chrysanthemums at Forest Hill.**  
Messrs. J. Laing and Sons have on view at the present time a representative collection of the best standard varieties for various purposes, and the plants occupy two large greenhouses that are specially set apart for their accommodation. Very striking and effective both for richness of colour and for size are the seedling varieties raised and distributed last season by Mr. W. J. Godfrey. We particularly noticed H. E. Hayman, apricot-yellow; Edward VII., rich claret-crimson; Bessie Godfrey, pure canary-yellow; Wallace E. Vowden, rosy carmine; and Godfrey's Triumph, rich ruby-crimson, varieties which form part of a set that any raiser might well feel proud of. From other raisers we get the ever-useful Soleil d'Octobre, Mme. Ed. Roger, always a curiosity on account of its peculiar green shade; W. R. Church, a very solid bloom of a deep rich plum-coloured crimson; and Lady Osborne, a pale pink Japanese of large size. Older varieties that have done well include Vivian Morel, Phœbus, Hairy Wonder, Eva Knowles, a beautiful warm golden terra-cotta-coloured Japanese of excellent form, and its sport, J. E. Clayton, a very pure pale yellow; Florence Molyneux, the big white Japanese of recent introduction; Elaine, Lady E. Clark, and Mrs. Molyneux are some of the best of the whites. Richer shades of purple and crimson are seen in Lionel Humphrey, Mr. T. Carrington, and Edwin Molyneux. Several large Anemone-flowered varieties are in good form, John Bunyan, W. W. Astor, and Mme. Lawton, a variety with very long florets, colour pale lilac-mauve, being the chief attractions in this class. Several freely-flowered plants of the rosy pink single variety, called Ladysmith, are employed for decorative effect, and are most useful for the purpose.

**Chrysanthemums at Swanley.**—For many years past the large show greenhouse at Messrs. Henry Cannell and Sons, of Swanley, has been the rendezvous of many a lover of the Chrysanthemum, and on the occasion of our recent visit there we were not at all surprised to find a

number of visitors from a local horticultural society making a tour of the establishment for the purpose of inspecting the novelties of the season. Mr. Henry Cannell, sen., has had a lengthy acquaintance with the popular favourite, and, in spite of increasing years, seems to maintain his old enthusiasm for a flower which has probably undergone more change than any other in the same period of time. This lengthy experience has necessarily led to a keen discrimination of the wants of the Chrysanthemum-growing fraternity; and, therefore, the Swanley firm has for years past had contributions from every raiser, both at home and abroad, for the purpose of testing their novelties and distributing such as have been proved to be really meritorious. Seedlings, too, have been grown at Swanley with the best of results, the consequence being that by the means already stated the collection is one of the most extensive and select in all its sections. A large span-roofed greenhouse, 160 feet by 25 feet, is devoted to the housing of the flowering plants in pots, of which at least 3,000 were on view at the time of our visit. The arrangement is at once simple and effective, for there is a central group of plants down the middle of the house, with a rather narrower border round the sides, thus presenting a fine display of colour such only as the Chrysanthemum can give at this season of the year. It is difficult to specify the origin of many of the varieties grown, but we may begin, for present purposes, with some of those from the continent. Mme. Liger-Ligneau, a close and compact looking incurved Japanese, with narrow florets, colour pale-lilac mauve, is the first to be noticed. We remember seeing this variety when it was awarded the gold medal of the American Chrysanthemum Society at the Paris Exhibition, 1900, as the best new seedling then shown. Calvat sends us Mme. Waldeck Rousseau, a bloom of noble proportions, deep in build, with broad-grooved florets of great solidity, and the colour a fine shade of velvety magenta-crimson, with a silvery pink reverse. Marquis Visconti-Venosta is another massive bloom from the same raiser, but better known. In O'tabite, the same raiser sends us a big bloom of a beautiful shade of pure reddish crimson, reverse golden bronze. Louis Leroux is deep and solid in build, colour deep golden-yellow; a Japanese flower with very broad-grooved florets. Mme. Paolo Radlaelli is now fairly well known, being one of a former series; a remark that also applies to several other prominently fine varieties. Among other novelties from the same source, Merlinia is very large but wanting in colour; F. S. Vallis a Japanese, with narrow, long, and drooping florets of a dark canary-yellow, should be heard of again; Louis Leveque; Mme. L. Chevraut, a soft, rosy flesh-coloured Japanese; La Fusion, an incurving Japanese, pale flesh colour; Mme. G. Chirac, and several others that might be named but for the exigencies of space, will all help to keep this eminent Frenchman's name still before us. Passing to those much farther afield, we must call special attention to an Australian seedling called Lord Hopetoun, a really striking Japanese of large size, with florets of medium width, the colour being a brilliant deep reddish crimson, and reverse of old gold; Mrs. Harry Emmerton, a large yellow Japanese; Mrs. Geo. Fairbairn, a rich golden buff, with florets curly at the tips; General Hutton, which was seen in good style last year, form, with many others, a batch of varieties of the highest promise. Nowadays it is curious to note that we seldom or never come across anything new in the Anemone and Pompon section, and rarely in the old-fashioned incurved type. Even the once clearly defined dividing lines that separated the Japanese into several distinct sections seem to be passing away, a result that must have been brought about largely by the intercrossing of the various types. In matters of taste there is no dispute, and certainly there is no difficulty, for the most fastidious grower, either for decoration or for show, to make a selection out of the novelties comprised in the Swanley collection, and for this purpose anyone has only to bear in mind the well-known trade motto of the firm, "Come and see."

number of visitors from a local horticultural society making a tour of the establishment for the purpose of inspecting the novelties of the season. Mr. Henry Cannell, sen., has had a lengthy acquaintance with the popular favourite, and, in spite of increasing years, seems to maintain his old enthusiasm for a flower which has probably undergone more change than any other in the same period of time. This lengthy experience has necessarily led to a keen discrimination of the wants of the Chrysanthemum-growing fraternity; and, therefore, the Swanley firm has for years past had contributions from every raiser, both at home and abroad, for the purpose of testing their novelties and distributing such as have been proved to be really meritorious. Marquis Visconti-Venosta is another massive bloom from the same raiser, but better known. In O'tabite, the same raiser sends us a big bloom of a beautiful shade of pure reddish crimson, reverse golden bronze. Louis Leroux is deep and solid in build, colour deep golden-yellow; a Japanese flower with very broad-grooved florets. Mme. Paolo Radlaelli is now fairly well known, being one of a former series; a remark that also applies to several other prominently fine varieties. Among other novelties from the same source, Merlinia is very large but wanting in colour; F. S. Vallis a Japanese, with narrow, long, and drooping florets of a dark canary-yellow, should be heard of again; Louis Leveque; Mme. L. Chevraut, a soft, rosy flesh-coloured Japanese; La Fusion, an incurving Japanese, pale flesh colour; Mme. G. Chirac, and several others that might be named but for the exigencies of space, will all help to keep this eminent Frenchman's name still before us. Passing to those much farther afield, we must call special attention to an Australian seedling called Lord Hopetoun, a really striking Japanese of large size, with florets of medium width, the colour being a brilliant deep reddish crimson, and reverse of old gold; Mrs. Harry Emmerton, a large yellow Japanese; Mrs. Geo. Fairbairn, a rich golden buff, with florets curly at the tips; General Hutton, which was seen in good style last year, form, with many others, a batch of varieties of the highest promise. Nowadays it is curious to note that we seldom or never come across anything new in the Anemone and Pompon section, and rarely in the old-fashioned incurved type. Even the once clearly defined dividing lines that separated the Japanese into several distinct sections seem to be passing away, a result that must have been brought about largely by the intercrossing of the various types. In matters of taste there is no dispute, and certainly there is no difficulty, for the most fastidious grower, either for decoration or for show, to make a selection out of the novelties comprised in the Swanley collection, and for this purpose anyone has only to bear in mind the well-known trade motto of the firm, "Come and see."

## SOCIETIES.

**HIGHGATE AND DISTRICT CHRYSANTHEMUM SHOW.** THE migration of this society's show to the Alexandra Palace at Muswell Hill, N., appears to have been a wise move, if we may judge by the magnificent exhibition got together on the 29th, 30th, and 31st ult. It was the first of the shows on the north side of the Thames, and, although the season is late, there was a remarkably fine lot of blooms staged for adjudication. This society was one of the pioneers in encouraging the exhibition of large blooms in vases, and on the present occasion there were more exhibits of this kind than have ever been seen before. The table decoration and other classes of decorative character were well filled, and the exhibits were also of a high order of merit. They were quite an important feature of the show. Groups and specimen plants were below the average, although special inducements in the way of valuable prizes were offered. Miscellaneous exhibits from the trade ably supplemented the efforts of the members, and together these made up an exhibition that even the National Society might be well proud of.

Of the more important classes, that for twelve vases Japanese Chrysanthemums, distinct, each vase to contain five blooms of one variety, to be faced all round, was the leading one. There were three grand exhibits, leading honours and the silver cup falling to the lot of Mr. J. Brooks, gardener to Mr. W. J. Newman, Totteridge Park, Totteridge. His flowers were very heavy, fresh and clean, and also of good colour. They were represented by J. R. Upton, Mrs. Barklay, W. R. Church (grand), Australie, A. H. Garrett, Mrs. T. W. Pockett, Mrs. G. Mileham, and others. A good second was Mr. G. J. Hunt (gardener to Mr. Pantin Ralli, Ashstead Park, Epsom), who had a bright lot of blooms. Third prize was won by Mr. J. Kirkwood, the Gardens, Grass Park Farm, Finchley, N.

For six vases of incurved varieties, distinct, arranged in the same way as the preceding class, there were three sets. The silver cup and money prize for leading position was won by Mr. Hunt, who had a nice even and fresh lot of blooms of Lady Isabel, John Lambert, Hanwell Glory, Empress of India, Miss Dorothy Foster, and Ada Owen. Second prize was awarded to Mr. A. Jones (gardener to Miss Wyburn, Hadley Manor, Barnet), who had larger blooms, but far less even than those in the first prize exhibit.

Of five competitors for a single vase of six Japanese blooms, distinct, arranged with any foliage for decorative effect, Mr. Brooks was again to the fore, with a large vase of good blooms of splendid colour, neatly and artistically disposed. Second prize was won by Mr. G. Frost (gardener to Mr. R. Wear, East Hill, Oakleigh Park, with blooms set up in an Oriental vase which harmonised beautifully with the flowers. Third prize went to Mr. J. Sandford (gardener to Mr. W. Wright-Ingle, North Finchley).

For a vase of Pompons arranged for decorative effect, Mr. S. North (gardener to Mr. F. Snowden, Broughton Lodge, Shepherd's Hill, Highgate), was placed first with a neat arrangement of mixed colours; Mr. D. B. Crane, 4, Woodview Terrace, Archway Road, Highgate, N., following with reddish crimson and yellow flowers; and Mr. S. Foster (gardener to Mr. R. Nivison, Tenterden Hall, Hendon, third).

An interesting class was one for twelve sprays of undisturbed Chrysanthemums arranged in a vase, and this brought out seven competitors, premier honours easily resting with Mr. D. B. Crane, who had large freely-flowered sprays of rich and warm colours. Second prize was secured by Mr. G. Saunders, 13, Victoria Cottages, Highgate, N., and third prize fell to the lot of Mr. A. Jones.

In a special class for one Japanese bloom, quality to be the leading feature, a superbly fine specimen of Miss Elsie Fulton, a pretty creamy white Japanese incurved variety, was a good first; Mr. J. Kirkwood taking second position with a bloom of Mrs. G. Mileham of good colour. In a class of a local character for six vases of Japanese Chrysanthemums, distinct, five blooms in each vase, for a challenge cup and a money prize, Mr. T. L. Turk (gardener to Mr. T. Boney, Southwood House, Highgate), was placed first with good blooms of General Buller, Mutual Friend, Mrs. Coombes, Mrs. Greenfield, Mrs. G. Mileham, and Mme. Gustave Henry. This being the second occasion of Mr. Turk winning the cup, it now became his property. Last year's winner, Mr. H. Stonebridge (gardener to Mr. J. G. Ronald, Bishopswood, Highgate), had to content himself with second position, although his blooms were little behind the leading set.

Mr. J. Brooks was first for twelve yellow Japanese, showing Mr. Louis Remy, Mr. Sandford being second, and Mr. A. Jones third.

For twenty-four Japanese blooms, in not less than eighteen varieties, there were five competitors, Mr. G. Impye (gardener to Mr. H. Mansfield, The Lodge, Abbotts Road, Barnet), leading with fresh even blooms of good colour; Mr. J. Brooks was a close second; and Mr. Sandford third. The decorative exhibits covered a considerable area, and the classes were well contested. The leading class for a dinner table decoration of Chrysanthemums, with ferns, grasses, and other foliage at will, in sets of three, found Mr. D. B. Crane in the premier position; Miss D. M. Oliver, 97, Tollington Park, N., was second; and Mr. J. Shrimpton (gardener to Mr. D. F. Cocks, Hornsey Lane, N.), was third. In a class for a single epergne, Mr. Crane was again first, followed by Mr. C. Halsey, Highgate, and third prize was secured by Mr. Sedgwick, Upper Holloway.

There were two competitors in the Coronation group class, arranged in an oval space, 20 feet by 14 feet. First prize was awarded to Mr. J. H. Witty, Highgate Cemetery; and second prize was secured by Mr. G. Saunders. Flowers and foliage plants were well arranged together, but the quality of the former was much below the usual standard. Miss A. M. Bevan, East Finchley, arranged a dinner table to seat fourteen persons, fruits and flowers being pleasingly intermixed.

Miscellaneous groups came from Messrs. W. Cutbush and Sons, Highgate, and Messrs. B. S. Williams and Son, Upper Holloway; Messrs. Wells and Co., Limited, Redhill, showed cut blooms and a mixed group of Chrysanthemums; Messrs. J. Cheal and Sons, Crawley, Apples, Dahlias, and hardy flowers; Mr. John Russell, Richmond, Apples and Pears in variety; Messrs. Wood and Son, Wood Green, horticultural sundries; and Mr. J. Williams, Oxford Road, Ealing, W., his pretty rustic table decorations. To Mr. W. E. Boyce, the secretary, much praise is due for the excellence of the arrangements.

## NATIONAL CHRYSANTHEMUM SOCIETY.

## EXHIBITION AT THE ROYAL AQUARIUM.

As usual the floral exhibits arranged on the fountains were one of the chief centres of attraction, the three competitors making most attractive displays. Mr. Norman Davis, Framfield, Sussex, was adjudged first, his exhibit being set up in a very charming and artistic manner. All types of the Chrysanthemum were represented, the small but pretty Pompons vying with the enormous and massive looking Japanese blooms of high quality for popular favour. Vases towards the base were artistically disposed and phenomenal blooms of new and choice sorts were plentiful. Richly coloured Crotons and graceful Palms and Ferns were arranged in perfect harmony. An uncomfortably close second was Mr. R. C. Pulling, Monkham's Nursery, Woodford, who had the great disadvantage of being in a very poor light. His arrangement was very little behind the leading exhibit, and his massive-looking exhibition blooms

Perkins, gardener to the Hon. W. F. D. Smith, Greenlands, Henley-on-Thames, outdistanced his rivals with a vase of superb blooms of Viscountess Cranbourne, a lovely and distinct bright and rich yellow flower, and a variety of his own raising. Second prize was secured by Mr. C. Edwards, gardener to Mr. H. W. Peal, Oakhurst, Ealing, with beautiful blooms of R. Hooper Pearson, grand colour and full; and Mr. C. Lane, gardener to Mr. E. H. Coles, Burntwood, Caterham, Surrey, was third.

For a vase of six blooms of any other colour, except white and yellow, Mr. A. Jefferies, gardener to Mr. John Balfour, Moor Hall, Harlow, Essex, led the six entries with splendid specimens of Mrs. Barkley; Mr. Perkins was placed second; and Mr. George Hewitt, gardener to Mr. Charles G. Green, Thetford Grove, Epping, Essex, was third.

Hairy-petaled Japanese varieties, arranged in a vase to the number of six, brought out only two competitors, and the quality was certainly much better than we have seen before. Mr. H. Love, Shanklin, Isle of Wight, was a good first with mixed varieties, including a good seedling of his own; and second prize was won by Mr. S. Foster, gardener to Mr. R. Nivison, Tenterden Hall, Hendon, with a pretty lot of blooms.

In a class for a vase of six Japanese blooms, one variety only, Mr. Henry Perkins, with a superb lot of his yellow seedling Viscountess Cranbourne, arranged with autumn-tinted and other foliage, was again in the leading position; Mr. H. Parr, gardener to Mr. F. A. Bevan, Trent Park, New Barnet, was second, with poorly-coloured blooms of Mr. A. Larret and with Vivian Morel (small); Mr. F. A. Coote, gardener to Mr. E. W. Howard, was third.

Mileham were handsome specimens. Mr. George Hewitt, with a good bright lot of blooms of even form, was second; and Mr. W. L. Bastin, Faringdon, third.

In the amateurs' division A, for twelve Japanese blooms, distinct, Mr. M. Rayment, gardener to Mr. W. Beech, North Ockenden, Romford, was first; Mr. Leonard Gooch, gardener to Mr. T. Wickham-Jones, Froester Lodge, South Norwood, a creditable second; and Mr. A. Page, gardener to Mr. G. W. Kilner, Ravenscroft, North Finchley, third.

For eighteen Japanese blooms, distinct, Mr. J. Childs, gardener to Mrs. Foss, The Priory, Totteridge, was first for a rather heavy lot of blooms, though lacking colour; and second prize was secured by Mr. A. Page with smaller, though neat and well-coloured blooms. The third prize was won by Mr. C. H. Martin.

Two contested the class for six Japanese, distinct, Mr. A. Robertson, gardener to Mr. F. J. Yarrow, St. John's Wood, being first; second, Mr. H. Pestall, gardener to Mr. F. S. Wigram, Elstton, Bedford; and Mr. J. Childs third.

Mr. A. Robertson again led in the class for six Japanese, one variety only, showing nice blooms of W. R. Church. Second honours went to Mr. C. H. Martin, with interesting blooms of Mrs. White Popham; and third to Mr. G. Denyer, Chatham.

## INCURVED CUT BLOOMS.

For thirty-six incurved blooms, distinct, in competition for the Holmes Memorial Cup, Mr. W. Higgs, gardener to Mr. J. B. Hawkey, Fetcham Park, Fetcham, Leatherhead, was a good first with large, even, and well-finished blooms. Specially good were Mrs. C. Crooks, Ialene, Frank Hammond, Edith Hughes, Major Bonnaffon, Miss Doris Cox, Globe d'Or, J. Agate, Miss Violet Foster, and Pearl Palace. The second prize was secured by Mr. G. J. Hunt, gardener to Mr. Pantia Ralli, Ashstead Park, Epsom, with a good lot of flowers, but not nearly so even as those in the first prize set. Mr. W. Mease came third, showing rather irregularly.

The vase class, for six vases of incurved blooms in six varieties, five blooms in each vase, was an attractive display. In this Mr. Higgs was again in the leading position, showing large and even blooms of Chas. H. Curtis, Nellie Southam, Lady Isobel, Robert Petfield, Mrs. R. C. Kingston, and Hanwell Glory. The second prize was won by Mr. G. J. Hunt, who had very heavy blooms, but less evenly finished than the first lot; and the third by Mr. W. L. Bastin, gardener to Sir Alexander Henderson, Bart., M.P., Faringdon, Berks.

No less than nine competitors were forthcoming in the class for twelve incurved blooms, distinct, Mr. Higgs again leading with a pretty and even lot of heavy blooms. His Topaze Orientale, Ernest Cannell, Globe d'Or, Robert Petfield, Duchess of Fife, Chas. H. Curtis, and Nellie Southam were in capital form. Second honours were secured by Mr. Bastin with heavy but rather uneven blooms; and Mr. C. Lane was third.

In the eight entries for six blooms of one variety of incurved there were some excellent blooms staged. Mr. W. Mease won the first prize with fine examples of Topaz Orientale; and with Duchess of Fife, Mr. C. Crooks, gardener to the Dowager Lady Hindlip, Hadsor, Droitwich, was placed second. The third prize was won by Mr. J. Sandford with good examples of Chas. H. Curtis.

## TROPHY CLASS.

There was but one entry for the national competition of Chrysanthemum and horticultural societies. This came from the Epsom and District Chrysanthemum Society, and the blooms were contributed by Messrs. W. Higgs and G. Hunt. The Japanese were good and of even form and capital colour, and the incurred were, as might be expected from these two exhibitors, much better than usual.

## OTHER CLASSES OF CUT BLOOMS.

A good competition was that for twelve blooms, in not less than six varieties, selected from Mr. A. J. Godfrey's introductions in 1901 and 1902, to include certain varieties. In this class Mr. R. Kenyon was in fine form, winning with grand flowers of Sensation, Mafeking Hero, Bessie Godfrey, Masterpiece, H. E. Hayman, Godfrey's Pride, and Kimberley. The second prize was secured by Mr. Charles Ritching, gardener to the Misses Baird, St. James's, West Malvern. These blooms were remarkable for their colour. The third prize was awarded to Mr. Charles Beckett, also for a capital collection.

Three blooms of the same novelties, staged in a vase in this instance, found Mr. A. Jefferies leading, and Mr. A. Shipway second. There were but two entries for twelve reflexed, distinct, Mr. T. Caryer, gardener to Mr. A. G. Meissner, Aldenholme, Weybridge, winning first prize with a pretty lot of blooms. The second prize was secured by Mr. Charles Brown, gardener to Mr. R. Henty, Langley, for a capital lot of blooms, Golden Christine being exceptionally good.

The same number of exhibits was forthcoming in the class for twelve large-flowered Anemones, distinct. Mr. Brown led with good examples. With a useful lot of blooms, Mr. A. Page secured second honours.

In the same order the last two exhibitors appeared in the class for twelve large-flowered Anemones, distinct, from which the Japanese were excluded. The first prize stand contained nicely-developed blooms with high discs.

For six bunches of Anemone Pompons, six blooms in each bunch and arranged in vases, Mr. Chas. Brown again excelled. They were, however, poorer than usual; the best sorts were Mr. Astie and Emily Rowbotham. Mr. J. Barrance was placed second with some interesting blooms.

SINGLE-FLOWERED CHRYSANTHEMUMS AT THE ROYAL GARDENS, KEW.

were the recipients of the praise of all. Third prize was placed to the credit of Mr. James Lock, gardener to the Hon. Mr. Justice Swiften-Haugh, Oaklands Lodge, Weybridge, who had a light and graceful display, but his blooms were far behind the others in point of quality.

## JAPANESE BLOOMS IN VASES.

The great vase class is usually the most interesting of the series, but on this occasion there were only four competitors. The contest was very keen, especially between the first and second prize winners. Premier honours, however, rested with Mr. F. S. Vallis, Bromham, Chippenham, who staged a very heavy lot of flowers, well set up, but not equal to those of last season. His twelve sorts were: Mme. Herrewege, M. Chenon de Leche, Australie, Mrs. W. Mease, Mr. Louis Remy, grand; Mrs. Barkley, splendid colour; E. Molineux, Mrs. J. Lewis, W. R. Church, Calvat's 99, very fine; Le Grand Dragon, and Mme. Carpet. Very close, indeed, was the second prize winner, Mr. Charles Beckett, gardener to Sir W. G. Pearce, Bart., Chiltern Lodge, Hungerford, his Loveliness, Sensation, and Mrs. Barkley being superb. Mr. W. C. Merideth, gardener to Mr. George Wilder, Stansted Park, Emsworth, was third.

Of the seven entries for a vase of six Japanese blooms, white, one variety only, Mr. W. Mease, gardener to Mr. A. Tate, Downside, Leatherhead, was placed first with beautiful blooms of Princess Alice de Monaco; Mr. Merideth following with grand flowers of Mme. Gustave Henry; and Mr. J. Sandford, gardener to Mr. J. Wright-Ingle, North Finchley, being third with less finished blooms of the same variety.

For a similar class, confined to yellow sorts, Mr. Henry

A similar class, confined to gardeners and amateurs, saw ten competing, and with lovely blooms of Mrs. G. Mileham, Mr. E. Jones, 51, Bowes Street, Bedford, was a good first; Mr. C. H. Martin, gardener to Mrs. Langton, Raymead, Hendon, was second with charming blooms of Lady Hanham; and Mr. A. Robertson, gardener to Mr. F. J. Yarrow, Abbey Road, St. John's Wood, was third with a pretty exhibit.

## JAPANESE CUT BLOOMS.

The Holmes Memorial Class for forty-eight Japanese blooms was well contested, Mr. F. S. Vallis leading the seven competitors with a very even and bright lot of flowers. Specially good were Mme. Waldeck Rousseau, Mrs. Barkley, Duchess of Sutherland (lovely rich yellow), Kimberley, F. W. Vallis (grand), Mrs. J. Bryant, Mr. T. W. Pockett, Mrs. G. Mileham, and others. A good second was Mr. R. Kenyon, The Gardens, Monkham, Woodford, who had many superb flowers; Mr. A. Jefferies was third; and Mr. W. Mease, fourth.

Eleven contested the class for twenty-four Japanese blooms, distinct, first prize being secured by Mr. H. Perkins with a very fine lot of flowers, Mrs. J. C. Neville, Countess of Harrowby, Mary Perkins, Henry Perkins, George Laurence, and Lady Mary Conyers being some of his best; with a good, fresh lot of blooms of good colour. Mr. W. Mease was second; and Mr. Alexander Smith, gardener to the Lady Superior, The Convent, Roehampton, was third.

There were fifteen exhibits in the class for twelve Japanese blooms, distinct, and it must have been very gratifying for Mr. H. Perkins to find himself occupying the leading position. His blooms of Henry Perkins, Australie, Lady Mary Conyers, George Laurence, and Mrs. George

Mr. Brown was again to the fore in the class for twelve large-flowered Japanese Anemones, distinct. They were a capital set, and proved how charming is this type of the flower with the long tasseled florets. The second prize was won by Mr. J. Barrance, gardener to Mr. G. W. Taylor, Hadley Bourne, Barnet, the quality being rather poor.

There was good competition for nine bunches of Pompons, six blooms in each bunch. The leading exhibit came from Mr. T. Caryer, who had very pretty blooms, pleasingly arranged. The colours were good, and the exhibit was well disposed in the vases. Mr. A. Page was a good second, though not so even, and Mr. Chas. Brown was third.

Fine, indeed, were the large and small-flowered singles. The three entrants made a grand show. The first prize was won by Mr. W. Abbridge, gardener to Mr. G. Lacey, Springfield House, Palmer's Green, N. His blooms of Elsie Neville, Edith (rose-pink), Anna Farrow, Earlswood Glory, and Felix were superb. An excellent second was Mr. A. Dean, gardener to Mr. W. Jordan, Hill House, Palmer's Green. Third prize, Mr. W. C. Pagram, Weybridge.

#### DECORATIVE EXHIBITS.

A good display was made in the competition for three eperges of Chrysanthemums with suitable foliage, &c., for table decoration. First prize was awarded to Mr. J. French, gardener to Mrs. Barclay, Ambleside, Wimbleton Park. He used yellow and orange flowers and appropriate foliage. Far more artistic was the second prize set which came from Miss C. B. Cole, The Vineyard, Feltham. The third prize exhibit was arranged by Mrs. Green, Harold Wood.

The class for two designs in Chrysanthemums brought out only two displays. The first prize set was very good, and embraced a harp in orange flowers with a cluster of pink tinted blossoms, and a golden ladder with a bow of white Chrysanthemums. This came from Messrs. Harwood Brothers, Balham. Second prize was awarded to Mr. Fred Oliver, 97, Tollington Park, N.

For the silver challenge cups offered by Mr. Percy Waterer, the first one was secured by Mr. D. E. Crane, Archway Road, Highgate, N. This was for a table 6 feet by 3 feet, for cut blooms of a decorative character and of small and medium size, judged for finish of bloom. Large vases of popular Pompons and decorative Japanese were freely displayed, and made an interesting and attractive exhibit. Second prize was awarded to Mr. Percy L. Johnson, North Gate, Bishop's Stortford, with larger blooms and as representative, and third prize was secured by Mr. A. Taylor, East Finchley, for a bright lot of flowers.

Another cup from the same source, but in this case open to lady members, found Mrs. D. B. Crane in the premier position. The table was an interesting one, seeing that it represented many of the small-flowered types, and was finished with foliage and other decorative material. Mrs. A. Taylor was second with a bright lot of charming flowers, very close to the leading display.

Bouquets were below the usual standard, the class for two hand bouquets or posies bringing out six competitors. Mr. E. H. Chitty, gardener to Mr. S. Hardy, Holmeley Lodge, Highgate, was placed first with a pretty idea, but with bad association of colours. Mr. J. French was second, and Mr. W. Grundy third.

#### PLANTS.

These were much below the average of what was the rule in former years. There were a few pretty plants of high merit, and these were seen in a class for four trained specimen plants, any varieties. Mr. E. Easey, gardener to Mr. F. Bishop, The Grange, Highbury New Park, N., was the only competitor. His umbrella-shaped plants were freely flowered and neatly tied out. Miss Watson, Colonel W. B. Smith, President Nonin, and Commandant Blusset were the varieties exhibited. The same grower was the only exhibitor of four standard-trained specimens, large-flowered varieties. These were not so pleasing, neither were they equal in merit to those in the previous class. Cleopatra, William Tricker, and Eva Knowles were the best of the four.

For four bush specimens there was but one entry, the plants in this instance being exhibited by Mr. W. Noble, gardener to Mr. H. T. Pitt, Roaslyn, 57, Stamford Hill, N.

The trained specimen Pompons were very good, although dreadfully formal. The leading exhibit came from Mr. F. Gilbert, gardener to Mr. M. N. Buttshaw, Kendal House, Blackheath, S.E., Pygmalion, Arbre de Noel, William Westlake, and Toussaint Marisol were shown in splendid character; Mr. F. Gilks, gardener to Mr. F. W. Frier, Bylock Hall, Ponder's End, was second with small and good plant.

A silver medal was awarded Mr. Gilks for a plant grown in the form of a crown, the variety being William Westlake (Pompon).

The amateur and single-handed gardener's classes were well filled, and did much to enhance the brilliance of the display.

Fruit and vegetables were well shown, and many prizes in the classes for the latter were offered by Mr. Robert Sydenham, Messrs. Daniels Bros., and others.

#### MISCELLANEOUS EXHIBITS.

Messrs. William Cutbush and Son, Highgate, N., had a charming group of miscellaneous flowering plants, such as Azaleas, Carnations, Spiraea, Heaths, Lilliums, &c. Silver-gilt medal.

Messrs. W. Wood and Son, Wood Green, N., exhibited horticultural sundries in variety; for instance, artificial manures, lawn mowers, orchid baskets, peat, &c.

Messrs. D. Dowell and Co., Hammersmith, displayed sundries; as also did Mr. J. George, 14, Redgrave Road, Putney.

Messrs. H. Cannell and Sons, Swanley, Kent, contributed a very handsome table of hardy fruit; the Apples were well coloured and in great variety, and the arrangement, though simple, was very effective. Silver-gilt medal.

Messrs. Daniels Brothers, Norwich, obtained a silver-gilt medal for a collection of vegetables that was much admired. The Onions and Leeks were grand.

Messrs. Pearce and Co., Holloway Road, N., showed some excellent little Chrysanthemum houses, frames, and heating apparatus.

The Ichthemic Guano Company, Limited, Ipswich, had a tastefully arranged exhibit of their specialties.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, obtained a large gold medal for a magnificent bank of Chrysanthemums, pleasingly arranged with the addition of foliage plants. Some of the blooms were very fine, notably Miss Mildred Ware, Matthew Smith, Florence Molyneux, and others.

Messrs. B. S. Williams and Son, Upper Holloway, N., showed Orchids and miscellaneous stove plants in excellent variety. Silver-gilt medal.

Hobbies, Limited, Dereham, made a beautiful display with Chrysanthemums, Roses, and Pelargoniums, all most tastefully arranged together. Gold medal.

Messrs. J. Hill and Son, Barrowfield Nurseries, Lower Edmonton, were given a silver-gilt medal for a really splendid lot of Ferns; all showed most skilful culture.

Messrs. H. Cannell and Sons, Swanley, had some very good cut blooms of Chrysanthemums on view, as well as a brilliant display of their unrivalled Pelargoniums, Cannas, and Begonias. Gold medal.

Messrs. Isaac House and Son, Westbury-on-Trym, Bristol, had a display of Violets in many lovely varieties.

Messrs. George Boyes and Co., Aylestone Nurseries, Leicester, showed some very good Carnations, pot plants, and cut flowers. Silver medal.

Mr. W. J. Godfrey, Exmouth, Devon, arranged a remarkably fine display of large Chrysanthemum blooms, many of the varieties included being of his own raising. We noticed Sensation, F. S. Vallis, Exmouth Crimson, Loveliness, Nellie Stevens, Wilfred Godfrey, and others, all really splendid flowers. Gold medal.

Messrs. T. Rochford and Sons, Broxbourne, exhibited a collection of retarded plants in bloom, including Lilliums, Spiraea, Lilies of the Valley, &c., all grandly grown. Gold medal.

Mr. J. Spink, Walthamstow, was given a silver-gilt medal for a good group of Chrysanthemums.

Messrs. J. Peed and Sons, West Norwood, showed a group of Chrysanthemums and various foliage plants.

Mr. John Russell, Richmond, Surrey, sent a collection of Apples and Pears of good quality. Mr. Russell also had a beatiful lot of Eurylatifolia variegata, Aucubas, and Crataegus splendidly berried. Silver medal.

Hardy fruit was shown by Messrs. J. Laing and Sons, Forest Hill, S.E. Silver medal.

Mr. W. Seward, Hanwell, showed several new English seedling Chrysanthemums, several of which obtained awards of merit.

Mr. J. W. Cole, Peterborough, showed Chrysanthemum Mr. E. A. Peak, a white seedling from Mrs. Weeks.

Mr. Vincent Slade, Taunton, showed zonal Pelargoniums.

Mr. W. J. Brown, Stamford, arranged a pretty table of hardy fruit. Silver-gilt medal.

#### ROYAL HORTICULTURAL SOCIETY.

##### DRILL HALL MEETING.

##### FRUIT COMMITTEE.

Present: Mr. George Bunyard (chairman), and Messrs. H. Esling, W. Bates, S. Mortimer, A. Dean, G. Kelf, W. Pope, M. Gleeson, G. G. Miles, J. Basham, F. L. Lane, G. Norman, J. Smith, James H. Veitch, G. Wythes, H. Somers Rivers, W. H. Divers, and J. H. Goodacre.

The Hogg memorial medal for fruit was awarded to His Majesty the King for some fourteen splendid Pine-apples. The fruits were from the Royal Gardens, Windsor (gardener, Mr. A. MacKellar).

The Hogg memorial medal for fruit was also awarded to the Duke of Portland, Belvoir Castle (gardener, Mr. W. H. Divers), for a collection of fruit. There were some sixty dishes of Apples and about the same of Pears, needless to say in all the best kinds. Warner's King, Bramley's Seedling, and Gascoigne's Seedling among Apples were superb, while the Pears generally were very fine samples; indeed, the entire collection was in a high degree excellent.

Thirteen fruits of enormous size of Belle de Jersey Pears were grown by Mr. J. G. Romilly, Longville Court, Jersey, and exhibited by H. Beecher, Esq., Jersey. The largest fruit weighed 3lb. 11oz., many others were nearly 3lb. in weight. Silver Banksian medal.

From the Horticultural College, Swanley, came a collection of "plantation-grown fruit," the Apples and Pears being of a good sample generally. Peasgood's Nonsuch was very fine and splendidly coloured. Vegetables also came from the same source. Silver Knightian medal.

Strawberry St. Joseph in pots was sent by Mr. Perkins, Greenlands, Henley-on-Thames.

From the Lady Warwick Hostel came preserved fruits in bottles, such as Raspberries, Currants, Plums, Cherries, Rhubarb, Gooseberries, &c. An example of the "steriliser" was also shown in which the fruits are prepared.

##### AWARDS OF MERIT.

*Strawberry St. Joseph.* Shown by A. W. Sutton, Esq., Bucklebury Place, Woolhampton.

*Rhubarb Topp's Winter.* Shown by Messrs. Veitch and Sons, Chelsea. The stems are long, slender, and of good colour.

*Grape Imperial Black,* shown by the Earl of Harrington, Elvaston Castle Gardens, Derby (gardener, Mr. J. H. Goodacre).

##### ORCHID COMMITTEE.

Present: Harry J. Veitch, Esq. (chairman), Messrs. J. B. Gurney Fowler, Henry Little, J. Wilson Potter, F. W. Ashton, W. H. White, W. H. Young, W. Boxall, H. A. Tracy, J. W. O'Dell, E. Hill, G. F. Moore, J. Cypher, J. Charlesworth, F. A. Rehder, James Douglas, H. Ballantine, and de E. Crawshay.

A cultural certificate was awarded to a finely-grown plant of *Dendrobium formosum giganteum*. From Captain Holland, Tetbury, Gloucestershire.

Messrs. J. Veitch and Sons contributed many interesting plants, mostly hybrid Cattleyas and Laelia-Cattleyas. Of the first: Portia, a rich coloured flower in two shades was shown; Ella, a bronzy flower with rich purple lip; Mrs. J. W. Whiteley, a rosy lilac with golden blotch internally; C. Mantinii, very free; and Laelia-Cattleya dominiana langleyensis; several very pretty Cyrtopediums, C. mennoni, C. Charlesworthii, C. spicerianum, C. Baron Schroeder, C. arthuriannum, and C. a. pulchellum being noticeable. Silver Flora medal.

From Tetbury Captain Holland sent *Dendrobium formosum giganteum*, with fine flowering sprays, for which a cultural commendation was given. D. Phalaenopsis var. the pretty Vanda kimballiana traced with graceful sprays of blossoms, and Cattleya labiata Westonbirt var. Vanda sanderiana was also shown.

J. Bradshaw, Esq., The Grange, Southgate, showed a superb lot of Cattleyas, many being C. labiata vars., together with Laelia-Cattleyas in charming variety; also C. aurea and a pretty hybrid Odontoglossum. Silver Flora medal.

Messrs. Hugh Low and Co., Bush Hill, had many good things, e.g., Cypridium insigne Sanderi, Cattleya labiata amesiana, very chaste; C. Mantinii superbum, Oncidium tigrinum, Pleione, Cypridium leeanum var. C. Niobe, &c. were also shown.

A small group of Cattleyas also came from J. Gurney Fowler, Esq., South Woodford, in which Cattleyas played a chief part, one huge plant bearing some ten monster heads of bloom.

Quite a charming lot of Cypridium insigne in variety were from C. H. Ferling, Esq., Southgate, and included Sanderi and the choicer forms generally, together with several fine plants of C. spicerianum and others. C. Charlesworthii was also in strong force. The whole of the examples were well grown and flowered. Silver Flora medal.

Messrs. Sander and Sons had Cypridium Coronis, C. leeanum giganteum x C. lynchianum, a noble flower, in which the dorsal sepal is very broadly margined white, C. Niobe splendens, C. Zebbia, Cattleya aurea, Dendrobium thrysiforme, and others.

Jeremiah Coleman, Esq., Reigate, had a beautiful lot of Cattleyas in variety, chiefly C. labiata var., with C. bowringiana, Dendrobium Phalaenopsis, &c.

Mr. James Cypher, Cheltenham, also had a beautiful lot of Cypridiums, such as Sanderi, leeanum, virginalis, Chantinii, and an insigne variety named Harefield Hall, a really magnificent flower, broadly margined white in the dorsal sepal, and strongly blotched brown on a golden ground.

A botanical certificate was awarded to Cynorkis purpurascens, a most pleasing flower with ample foliage. From Messrs. Sander and Sons, St. Albans.

##### CERTIFICATED ORCHIDS.

The following received an award of merit:—*Cattleya Mrs. Pitt.*—Sepals soft rose-pink, labellum golden-orange, with white margin; very striking. Shown by Mr. H. T. Pitt, Stamford Hill.

*Oncidium Mantinii superbum.*—Brown and chocolate, the lower sepal freely blotched on a golden ground. Shown by F. Wellesley, Esq., Woking (gardener, Mr. J. Gilbert).

*Cypripedium Thalia.*—From C. insignis Chantinii and C. x bowringiana. A fine form of insigne with a handsome, well-coloured dorsal sepal. Shown by Messrs. James Veitch and Sons.

*Cypripedium Evelyn Ames superbum.*—Resulting from C. leeanum giganteum x C. Calypso var. Oakwood. A magnificent flower, the dorsal sepal broadly margined with white and lined with purplish crimson; lip and sepals glossy brown. Shown by Messrs. Sander and Sons, St. Albans.

*Cypripedium Transvaal superbum* (C. chamberlainianum x C. rothschildianum).—Of the former parent there is ample evidence in the hybrid, with its wide side lobes blotted and hairy, and with a slight curve. The dorsal sepal is green, with dark lines; the pouch of a reddish purple. The spike carried one flower and two buds. From Messrs. Sander and Sons, St. Albans.

(Report of the Floral Committee unavoidably held over.)

## ANSWERS TO CORRESPONDENTS.

**Names of Plants.**—M. E. H.—The white-flowered shrub is *Abelia chinensis*; the other specimen was very much withered, but appears to be *Ceratostigma plumbaginoides* (syn. *Plumbago Larpetae*). The reason the flowers do not open as they should is possibly due to the plants being starved; you might try planting them out in a warm sheltered corner in good soil, or if you prefer to have your plants in pots, repot into rich loamy soil.—Mrs. Riddell-Webster.—1, *Ligustrum japonicum*; 2, *Crocus asturicus*.

**Names of Fruits.**—H. P. K.—1 and 3, *Dumelow's Seedling* (Wellington); 4, *Golden Noble*; 5, *Northern Greening*; 6, *Kerry Pippin*.—J. M.—1, *Flander's Pippin*; 2, *Malster*; 3, *Cox's Pomona*; 4, *Hambledon deux ans*; 5, *Pennington Seedling*; 6, *Old Hawthornden*; 7, *Tibbett's Pearmain*.—Constant Reader.—A, *Swan's Egg*; B, *Euré Diel*; C, *Josephine de Malines*; D, *Burré de Capiaumont*; E, *Burré Rance*; F, small round *Orange Bergamotte*; F, small long, bad example, not recognised; C and E are good quality Pears, the others are only second-rate.

**The Gardeners' Company.**—Sir Marcus Samuel, Lord Mayor-elect, will be Master of the Worshipful Company of Gardeners during the next year.

# THE GARDEN

No. 1617.—VOL. LXII.]

[NOVEMBER 15, 1902]

## ROOF GARDENING.

**D**WELLERS in cities and large towns are usually supposed to be debarred from participating in the delights of gardening by reason of their position and environment, yet we shall hope to show that since roof gardening has been proved to be possible the citizen without a square yard of ground may, if he will, enjoy the sweets of home-grown flowers equally with his country cousin. If we are to judge from the charming illustrations of roof gardening in New York, that many from time to time must have seen, we have yet much to learn as to the possibilities of this form of gardening. It may be that the roofs of American houses are so built as to offer greater facilities to the gardener in his endeavours to transform their barren dulness into a picture of living beauty, and this to a certain extent we believe to be true. Nevertheless, if we take roof gardening in its widest sense, and under this title allow the inclusion of verandahs and balconies, of which many a house can boast that does not possess a roof suitable for gardening, in our metropolis alone there must be thousands of opportunities for roof gardening, and it is safe to say that most of them are ignored.

To those so fortunate as to live both in town and country at different periods of the year, and especially those who are fond of their flowers, roof gardening should appeal, because it enables them still to enjoy their favourite recreation; that it is confined to somewhat narrower limits should not diminish but rather tend, perhaps, to increase its interest. To those who are obliged to spend week in week out in the town, roof gardening ought to have still greater charms and fuller possibilities. There are those who think that practically no plants will grow satisfactorily in large towns, because of the smoke-laden and foggy atmosphere, yet were such persons only to attempt the culture of plants most suitable a pleasant surprise would be in store for them. It is true that he who attempts gardening in London or any other city must be prepared to lose a greater percentage of plants than if these were grown under more favourable conditions in the country.

It almost goes without saying that in roof gardening the cultivation of plants will have to be carried out with the help of pots, boxes, barrels, and tubs. It would neither be satisfactory nor feasible to have them permanently

planted in beds of soil, and, besides being so much more convenient and better suited to the well-being of the plants, the use of these various articles gives one the opportunity of completely altering the arrangement of the roof garden year by year. It is not advisable to make use of many perennial plants, and those chosen should, if possible, be evergreen. Annuals will succeed better as a rule, will give less trouble, and will provide a more brilliant and varied display of flowers. When annuals are largely employed, the boxes, tubs, &c., can be cleared in the autumn and prepared for the reception of bulbs, and what dreams of delightful spring flowers does not the mention of bulbs bring to the mind of the town gardener! The roof garden perhaps would lose its best opportunities were the planting of bulbs to be neglected.

So many lovely bulbous flowers can be easily grown even in a town. To say nothing of Crocuses, Snowdrops, Tulips, Daffodils, and Hyacinths, which everyone knows and grows, there are the Scillas, Anemones, Winter Aconites, Ranunculi, the lovely early-flowering Irises, and Muscari, all in their numerous species and varieties. As most of these may be lifted in the spring and stored away till autumn to make room for the plants which are to keep the roof garden gay throughout summer, they are particularly well suited to this purpose. Bulbs may be grown in any of the receptacles we have mentioned, although they will look by far the best in shallow boxes.

The cultivation of plants in barrels is one of the most delightful attributes of roof gardening. We have seen some beautiful pictures, notably in the gardens at St. Fagans, Glamorgan, produced by plants growing in barrels, the latter being completely smothered with foliage and flowers; it would be almost impossible to say, did one not already know, that the plants were growing in such a common place and easily procured article. During April and May it is not difficult to have the Rock Cresses in white, purple, and other colours (*Arabis albida*, *Aubrietas Leichtlinii*, and *græca*) tumbling down the sides of the barrel and covering this with cascades of beautiful blossom. Other charming flowers that from March to June will make one forget there are barrels beneath them are those lovely Pinks (*Dianthus caesius* and *D. fimbriatus*), *Saxifraga hypnoides*, *Gypsophylla cerastoides*, *Iberis correaefolia* and *I. sempervirens* (Candytufts), the ever-welcome *Myosotis dissitiflora*, and *Veronica repens* and *V. rupestris*. From June

onwards we have the pretty *Campanulas*, *C. carpatica* and *C. muralis*, as well as the *Centranthus*, while *Erigeron mucronatus*, *Lobelia paxtoniana*, Ivy-leaved Geraniums, Carnations, Verbenas, and Heliotrope will ensure a wealth of bright colour for many weeks to come.

For deep boxes one might use Carnations, Fuchsias, and Ivy-leaved Geraniums; all are extremely suitable by reason of their loose habit of growth; they tumble about in a charming manner and transform the boxes into masses of pleasing flower and foliage. In shallow boxes one might plant *Lobelia*, *Mesembryanthemum*, *Portulaca*, *Nemesia*, &c., and in tubs what could be more appropriate than such good garden plants as *Choisya ternata*, Myrtles, sweet-scented Verbena, *Spiraea Bumalda*, *S. Anthony Waterer*, and the Bay Laurel. With such a wealth of suitable material at hand, which, moreover, has the merit of being inexpensive and easily grown, those to whom its charms appeal should have no difficulty in successfully carrying out this gardening on the roof, so greatly neglected, yet so full of possibilities.

## RIVIERA NOTES.

RIVIERA gardens are this year a striking contrast to those left behind in the North of England, where the marks of a cold, ungenial season were only too evident in belated blooms and weather-beaten plants. The extreme heat of part of the summer here, followed by a heavy downpour of rain in early October, has produced a flush of autumn flowers that is amazing to the newly arrived, who find that for the present these semi-tropical mornings entirely preclude all idea of autumn. The crop of winter Roses is, however, not promising. The autumn rains, though late in arriving, found the Roses less ready to respond to them, as the spring rains continued till late in June, when the plants should have been resting; hence this very poor look-out. Carnations need cooler weather after the trying heat which the Palms and semi-tropical plants have so enjoyed, as also the tender climbing plants such as *Ipomoeas*, *Lantanias*, *Minas*, and *Heliotropes*, which are in perfection just now. The wreaths of sky-blue *Ipomoea* and cream and crimson spikes of *Mina lobata* are "a sight for sore eyes" in the morning sunshine, with *Zinnias*, *Plumbagos*, *Senecios*, and countless other flowering plants around. *Perimonium discolor* is a very dainty little shrub now in flower. Its bouquets of neat golden Daisies and its pointed, slender leaves make it noticeable even in such a mass of colour. Shrubby *Begonia Le Vesuve* is exceedingly pretty in the shade of a group of *Bananas*; it should b

a good greenhouse plant, and is a change from the too-pervading scarlet of *Salvia splendens*. The great Tree *Salvia* (*S. frutescens*) is just in beauty; its heavy heads of blossom weigh down the tall stems rich in luxuriant foliage. The Tree Dahlias, too, are just out, and receive all the admiration they truly deserve where white or cool-coloured flowers are so wanting. Irises are well to the fore with *I. alata*, *I. stylosa*, and the winter-flowering form of *I. germanica* in good flower. The *Yuccas*, now in abundant flower everywhere, look extra well with a groundwork of this useful Iris.

Persimmons are splendidly decorative just now with their crimson leaves and fruit of many shades of orange and red, and the baskets of them shown at the flower show at Nice last week were tempting indeed to the eye, though I doubt if as yet they are fit for table. As usual, the Chrysanthemum show here was a very poor thing. In the first place, it is far too hot for first-rate flowers; and, secondly, they are not grown really well. There were, however, some shown grafted on the Paris Daisy, well known as *Anthemis*, and its dwarfing effect on such a variety as *Mme. Carnot* makes it worth recording. One plant not 3 feet high bore five good blooms. There is one excellent yellow, Paul Sain, which is a first-rate bush plant, and one white, with its petals cut up at the buds into a tassel, is quite worthy of its name, *Inimitable*. It may not be new to all, but it is both distinct and good.

EDWARD H. WOODALL.

#### EDITOR'S TABLE.

##### MALMAISON CARNATIONS.

From Lady Tweedmouth, Guisachan, Beauly, N.B., we receive some magnificent blooms of Malmaison Carnations. In an accompanying note Lady Tweedmouth says: "Just a few Malmaisons for the Editor's table, to show what can be grown in the far north. The plants at present are one mass of bloom, and this is likely to continue for some time to come." The varieties sent were Beauty of Guisachan, a lovely pale pink, delicately striped with red; Princess of Wales, a rich deep pink; and Sir Charles Freemantle, red, with a faint tinge of salmon colouring.

##### FROM A HEREFORD GARDEN.

Mr. H. Southall, The Graig, Ross, Herefordshire, sends "a few cut flowers gathered this afternoon (November 7), as a proof of the unusual character of the season. The tenderest out of door plants, such as Dahlias, Nasturtiums, and Cistus are still uninjured, although they are occasionally over as early as September 28. *Kniphofia maxima globosa* is the latest of these to flower. There are still some two dozen handsome spikes left. *Lilium auratum* is out of doors and unprotected. Summer and autumn Chrysanthemums are in full beauty still, and overlapping the later November kinds. *Bignonia radicans*, *Schizostylis coccinea*, *Cistus crispus*, and many other flowers, including Dahlias, are still as gay as ever. The tints of the Horse Chestnuts, Maples, and Sumachs have been a good contrast to the adjoining Pines, whilst *Vitis purpurea* and *V. Coignetiae* have vied with *Amelopsis Veitchii* in their rich colouring. Other trees, such as the Judas Tree, *Paulownia imperialis*, *Polygonum cuspidatum*, *Acer colchicum rubrum*, Guelder Roses, *Cesalpinia japonica*, &c., have blended most effectively."

##### NEW MICHAELMAS DAISIES.

Mr. Amos Perry, Winchmore Hill, N., has sent us a splendid selection of these beautiful autumn flowers. Many varieties are represented. Mr. Perry says that all have been thoroughly proved and are improvements upon existing varieties. We give a list of them with brief descriptions:—

Aster *Amellus* Nancy Perry is one of the best;

the colour is a rich lavender-blue, quite an unique shade; the plant grows about 2½ feet high.

A. A. Fringed Beauty is quite a new break, in colour the flowers are a rich violet, and the ray florets are deeply cut, giving the former a pretty fringed appearance.

A. A. Perry's Dwarf is another distinct variety, growing barely 9 inches high; it has a pretty branching habit and will be suitable for the rockery or edge of border.

A. A. Perry's Favourite was well described in THE GARDEN recently, and is probably the finest pink of this section. It originated at Winchmore Hill five years ago.

A. A. Rosy Gem is another very distinct colour, a rich rosy lavender. The plant reaches 2 feet high,

COREOPSIS

GRANDIFLORA.

has pretty branching growth, and remains in flower a long time.

A. A. Giant, growing fully 3 feet high, has a loose branching habit; flowers violet-blue.

A. turbinellus elegans is a distinct form raised at Winchmore Hill some years ago; the habit is identical with that of *turbinellus*, the flowers opening pure white and changing to rosy lilac.

A. Novi-Belgii Perry's White is one of the finest whites, flowers of great substance, pure white, fully 2½ inches across, and lasting a long time; of sturdy habit, about 3 feet high; its great value lies in the flowers remaining white.

One of the finest and most distinct seedlings this year Mr. Perry considers to be

A. Novi-Belgii "The Garden," described last week. The plants being well furnished to the ground, he says have been a splendid feature.

#### NOTES OF THE WEEK.

##### FORTHCOMING EVENTS.

###### CHRYSANthemum SHOWS.

November 15.—Blackburn, Chorley, Bradford (each two days), and Burton-on-Trent.

November 17.—Meeting of the National Chrysanthemum Society's floral committee.

November 18.—Royal Horticultural Society's Drill Hall meeting.

November 19.—South Shields and Northern counties (two days).

November 20.—Leamington, Warwick and district (three days at Leamington).

**The Horticultural Hall.**—Just now, when interest is being centred upon the project of a Horticultural Hall for London, it may be serviceable to some of your readers to direct attention to the recently published "Transactions of the Massachusetts Horticultural Society for the year 1901, Part II." In it they will find an account of the dedication of the new Horticultural Hall recently erected in Boston by that society, with a photographic view of the exterior. Plans and a description of the building are also given. A very good picture of the interior of the new library appears in the same number.—C. H. P.

**Coreopsis grandiflora.**—This is one of the most useful plants for the mixed border, the large bright yellow flowers are produced in profusion at the end of May, and continue to appear throughout the summer. This *Coreopsis* will flower from seed sown the same year, though many gardeners treat it as a biennial. Sow the seed early in April, and if the soil is rich and the plants are not crowded a glorious display of flowers will result in the autumn. It is one of the brightest and most graceful flowers of the garden.

**Horticulturists and the sale of poison.**—The Departmental Committee which was appointed to consider the sale of articles containing poison used in agriculture and horticulture has nearly finished its labours. The draft report which has been prepared has been practically approved. It is understood that it will recommend the addition of a third schedule to the Pharmacy Act, by which persons other than are authorised by the Pharmacy Acts will be licensed to sell articles containing poisons that are used in agriculture and horticulture, subject to regulations to be drawn up by the Privy Council. These regulations will, it is expected, provide that the articles shall be in special bottles and have special labels, and their general effect will be that articles like sheep-dip and insecticide will be freed from some of the restrictions that now exist.—*Standard*.

**The Royal Gardeners' Orphan Fund.**—The Right Hon. the Earl Carrington has kindly consented to preside at the next anniversary festival of this charity, which will take place at the Hotel Cecil, on Tuesday, May 5, 1903.

**Valuable to young gardeners.**—The fees usually charged in horticultural colleges are beyond the means of the ordinary gardener, who is none the less conscious that his chances of passing the Royal Horticultural Society's examination would be greater if he could supplement his practical training by spending a short period in the laboratories of a horticultural college. At Reading a limited number of men of this class are granted a course of free instruction for six months and a maintenance allowance, together with railway fare to and from Reading. They are required to devote their time between work in the laboratories to preparation for the Royal Horticultural Society's examination and in the college gardens at practical work under the direction of Mr. Patterson. Particulars may be obtained from the registrar.

**The Gardeners' Company.**—Sir Marcus Samuel, Lord Mayor of London, is the present Master of the Worshipful Company of Gardeners. It was mentioned in our last issue that the Lord Mayor would be Master during the coming year.

**Royal Horticultural Society.**—The next fruit and flower show of this society will be held on Tuesday next in the Drill Hall, Buckingham

Gate, Westminster, 1—4 p.m. A lecture on "Spraying Fruit Trees and Packing Apples, as practised in Canada," will be given by Mr. Cecil H. Hooper, F.R.H.S., at three o'clock. At a general meeting, held on Tuesday, the 4th inst., forty new Fellows were elected, amongst them being Lady Julia Follett, Major Charles A. Leslie, Major George A. Marshall, and the Hon. Mrs. Harbord, making a total of 1,045 elected since the beginning of the present year. The society's annual examination in the principles and practice of horticulture will be held on Wednesday, April 22, 1903. Full particulars may be obtained by sending a stamped and directed envelope to the society's offices, 117, Victoria Street, London, S.W. The questions set at all the previous examinations are now published, price 1s. complete.

**The Beauty of grouping.**—A misprint occurs in my notes in THE GARDEN of October 25. I intended to say that those of us who own small gardens, while making general effect our chief consideration, might reserve one large bed for those species which give us the most pleasure. The writer of the interesting leader in the same number warns us that in placing short plants in front and tall plants behind we must carefully avoid having too regular and even a slope. It seems to me that any precaution of this kind is needless, because different seasons—with rainfall and sunshine varying in quantity—have such different effects upon different species that we could not, even if we would, obtain a slope like a slate roof.—F. A. STURGE.

**Crocus speciosus.**—In an old number of THE GARDEN a writer says that Colchicum and Crocus become deeper every year, and should therefore be dug up every few years. A wise gardening friend of mine rather questions this statement, but my Crocus speciosus in grass, which have been very pretty for years, are gradually disappearing, and I should be very glad to know your experience.—F. A. STURGE, Coed Efa, near Wrexham.

**Rose Mme. Jules Grolez.**—I have to thank my friend Mr. H. E. Molyneux and your other correspondents for their notes anent the scent of this Rose. I would point out that this garden is not by any means a warm one, and as the bed containing Mme. Jules Grolez is placed on a piece of ground sloping to the north, the position and the extremely cold summer have undoubtedly affected the fragrance of this splendid variety. Mr. Molyneux's garden is a warm and sheltered one, mine is, unfortunately, just the reverse.—ARTHUR R. GOODWIN, Kidderminster.

My experience with the above Rose is that it is sometimes very pleasingly, though not powerfully, fragrant, and at other times possesses but a very faint odour, a trait that is not uncommon with many other Roses. I have even found Rose Maman Cochet not entirely devoid of scent on one or two occasions. Strong winds and heavy rains are apt to destroy the fragrance of flowers considerably, as some particular state of the atmosphere, on the other hand, is instrumental in increasing this. M. Guillot's lovely Hybrid Tea is not only fragrant with me in the garden, but a strong-growing, most free-flowering variety, and especially beautiful in the bud and half open stage.—GEORGE H. ELLWANGER, Rochester, N.Y.

**Peach Thames Bank.**—I am pleased to see this handsome late Peach brought under notice by your correspondent "S. H. B." (page 281), and to find from his remarks that it is still under cultivation, for, unlike your correspondent, I unfortunately overlooked the dish exhibited at the Crystal Palace fruit show. It deserves all that "S. H. B." says in its favour, and is, in my opinion, the best of the late yellow fleshed varieties, notwithstanding the undoubted usefulness of Exquisite as a late Peach. Its large size—many of its fruits reaching 11 inches in circumference—and its rich yellow skin, suffused and streaked with crimson on the sunny side, give it a remarkably handsome appearance, which, together with its good flavour, ought to have secured for it a far better position than it evidently ever attained amongst cultivators and exhibitors of fruit. I found a young tree of Thames Bank here, planted in a late house when I

took charge of these gardens some 29 years since, and observing its comparatively small, delicate unhealthy looking blossoms, was prepared for a bad set of fruit; however, the apparent weakness subsequently proved to be natural, for the tree possessed a good constitution, and always set a good crop. So pleased was I with this variety for late use that on more than one occasion I drew attention to its good qualities in the gardening papers, and exhibited it at one of the Royal Horticultural Society's shows at South Kensington. Our old tree has now been uprooted, and we have failed to replace it or find the name of Thames Bank in any fruit catalogue, but I hope that "S. H. B.'s" note may cause it to be looked up, for it is certainly a better Peach than are many late ones enumerated in the catalogues. Perhaps the exhibitor of the dish staged at the Crystal Palace will place some buds in the hands of a nurseryman, who may be willing to work up a stock of young trees. I recollect speaking to the late Mr. Rust about this Peach, and I think he stated that it was first distributed by Messrs. Osborne.—T. COOMER, Monmouth.

**Rose Ella Gordon (H. P.).**—This will probably be a record year for autumn Roses, and it is really wonderful to see the Rose garden just now (November 3). We could cut hundreds of splendid flowers. One of the finest of the H. P.'s this year is Ella Gordon. It is always good in late autumn, in fact I think it is one of the best red H. P.'s for this season. Resembling its parent, Mme. Victor Verdier, this splendid variety differs in its more vigorous growth and more perfectly formed flowers. The petals are smooth, very substantial, and of symmetrical globular shape. It is just the Rose for a bold bed, the fine towering shoots crowned with blossom, being very conspicuous in the distance. As a vigorous headed standard, or as a pot Rose Ella Gordon is alike most useful.—P.

**Gomphia decora.**—Apart from Gomphia Theophrasta (noted on page 191) as being in flower in the Palm house at Kew, there is a second species—G. decora—which each recurring autumn used to form an attractive feature in the same structure, and it is doubtless still there. This species is a native of Brazil, from where it was introduced in 1868. In its native country it attains the dimensions of a tree, but will flower freely here as a pot plant. In this way it forms a freely branched specimen clothed with broadly lanceolate leaves of a pleasing shade of green and leathery in texture. The flowers, which are borne in closely packed spikes, are individually about an inch in diameter and of a bright yellow colour. The flowering season of this Gomphia usually extends from August to nearly Christmas, a period which is not very prolific of bloom among stove plants in general. Its cultural requirements are not at all exacting, succeeding as it does under the treatment given to the general run of stove plants. When once established in good sized pots it will stand for years and flower well without repotting. Cuttings of the half ripened shoots are not at all difficult to strike if put into pots of sandy soil in a close propagating case in the spring and early summer months. Besides the specific name of decora it is also known as Gomphia olivaeformis.—T.

**Ageratum.**—Shades of blue are none too plentiful in the flower garden during summer and autumn, and having regard to this and the general popularity of the colour, I think that Ageratums are deserving of more extended culture. In planning formal beds for next year it would be well to consider the dwarf kinds of Ageratum, for their colour blends well with the majority of summer flowering plants usually made use of for this style of bedding. Ageratums are of extremely easy cultivation, and several really good dwarf profuse flowering varieties have been introduced of late years which should help to popularise this plant as a bedder. They are readily increased by cuttings taken from the plants in autumn. Our plan is to insert ten cuttings or so into a 6-inch pot filled with light sandy soil and plunge these in fibre on a mild hot-bed. When rooted they are placed on shelves in a temperate house near the roof glass for the winter. In February we commence propagating

from them, and by the time it is safe to bed out we have sufficient plants to fill the beds. During the past mild autumn the flowers of Ageratum have survived all others in the Italian Garden here. The plants were cleared from the beds at the end of October, being then full of blossom, whilst all other subjects were past their best. No special treatment is necessary for Ageratums, they will thrive in almost any soil. Strong, well hardened plants should, however, be available at bedding time, and afford abundant supplies of water during dry weather, and give a mulching of cocoanut fibre or spent Mushroom bed manure.—H. T. MARTIN, Stoneleigh.

**Rose Papa Lambert.**—This fine showy Hybrid Tea seems to improve with acquaintance. The deep very double flowers are splendid in autumn as they are in summer, the pure rose colour becoming much intensified at this late season. It is deliciously fragrant, and altogether Papa Lambert is a Rose that must be planted in every well ordered collection. The last few days of October were remarkable for their Roses, and none was better as a show bloom than Papa Lambert. It is a low growing kind, and should be given a prominent position near the front. It is a great mistake to grow such a Rose in standard form, its more fitting style being the bush. The plants of rather low growth harmonise well with Lady Mary Fitzwilliam, White Lady, and Tennyson. For pot culture it is superb, the fine bold flowers being much admired.—P.

**Notes from Baden-Baden.**—For covering certain portions of rockwork Linaria pallida is a capital plant. The leaves are smaller and of a deeper green than those of L. Cymbalaria, but its merit rests in the flowers, which are three times as large, much brighter in colour than the latter, a shining mauve-purple. It is cut down in cold winters, but the roots remain healthy, and push with energy in spring; the freely-produced flowers continue until November. The Plattensee variety of Sternbergia lutea, which is in full leaf, and flowers from August until October, has much larger flowers than the typical plant. During summer and autumn Lavatera cachemiriana was showy; it is an elegant half shrubby plant, about 1½ metres high, and lavishly produces hundreds of large lustrous pale rose flowers. Owing to adverse weather many showy plants, especially bulbs, have failed to flower well, and now it is too cold.—MAX LEICHTLIN, Baden-Baden.

**Aster salicifolius.**—Allow me to call attention to a late and very pretty but little known North American Aster, which is hardly yet (November 8) in full bloom. The main stems are few and stout, 2½ feet long, and bend over with the weight of the flowers, so that they all show on one side. The branches begin a few inches from the base, and are crowded with small shoots growing from the axil of every leaf, the whole forming such a compact mass of pink flowers as I have seldom seen in any Aster. The growth at the base is so close that a plant even at two or three years old is difficult to divide, but the stems root easily when pulled off close to the ground. I had it a few years ago from a gardener near Aix, in Savoy, from which it is called by me Tresserve. It has been submitted to a good authority, who, after comparing it with the types in Kew Herbarium, pronounces it to be undoubtedly Aster salicifolius, of Aiton's "Hortus Kewensis," so we may conclude that it was grown in Kew Gardens soon after the middle of the eighteenth century. It is now included in the "Kew Hand List." Asa Gray says it is a native from Canada to Texas, being very plentiful in the valley of the Mississippi. Many Asters which extend over a wide range vary much in stature and colour, and this Tresserve form may perhaps be more attractive than others of the same species; but as a very late garden ornament I have hardly said enough in its praise.—C. WOLLEY-DOD, Edge Hall, Malpas.

**New forms of perennial Asters.**—When I read the editorial note on page 258 about the desirability of getting improved forms of Asters of the Amellus type, I was struck once more by the diversity of personal taste in flowers. My own aim would be to produce small-flowered

types resembling the cordifolius set. These always seem to me to be so graceful and attractive, and such a contrast to the general run of autumn flowers. I want to get a pink cordifolius, and as a step that way I have succeeded in getting a small-flowered bushy pink sort that I hope to raise some seedlings from with a taller habit. The flowers are too large as yet for me, although it is a pretty sort, quite distinct from the pink *A. levigatus*.—T. J. W.

#### **Crocus asturicus atropurpureus.**

It is quite amusing to find what a profound ignorance exists, even among people who devote great attention to gardening, of these autumn-blooming bulbs. I am surrounded by garden enthusiasts, and yet when I produce a few bloom of this pretty dark purple sort they are greeted with astonishment, and I am asked how I manage to get them at this time of the year. I am hardly believed when I say they are growing in the ordinary border with as little care and attention as the commonest flower, but of course it is so. Pretty as *Crocus speciosus* is, its blue is cold compared with the warm deep purple of this. I wish it were cheaper, so that one could plant it by the hundred instead of by the dozen.—T. J. WEAVER, *Thirlwood*.

#### **Chrysanthemums at Liverpool.**

As in former years the Parks and Gardens Committee of the Liverpool Corporation have made arrangements for a special exhibit of Chrysanthemums at the Botanic Gardens and Sefton Park, and that these exhibitions are appreciated by the citizens is clearly shown by the large number of visitors. The same number of plants are grown as in previous years, viz., 2,000 at the Botanic Gardens, 800 being grown for large blooms, the rest as bush plants; at Sefton Park the number is 1,700, of which 900 are reserved for large blooms. Those at the former place are earlier, and include many fine flowers, and undoubtedly may be termed the finest lot yet shown. Those at Sefton Park are somewhat later with many promising buds; the ones fully out are remarkable for their colouring and freshness.—R. G. W.

**Cyclamen europaeum.**—I have this Cyclamen, or what I believe to be it, doing fairly well at present, though as the corms, which were sent to me from the neighbourhood of Vienna, were only planted last year it is too early to speak with much assurance. At any rate the plants have thrown up good leafage. The leaves are round, purplish crimson on the undersides, but some of them show slight marbling of a lighter tint on the dark green. I notice that Mr. Wolley-Dod says they are without variegation, which makes one doubtful if they are true to name. I was told that in Austria they flowered in the summer. The corms are planted according to Mr. Wolley-Dod's advice, given some years ago in THE GARDEN, 3 inches deep in leaf-mould. As regards *C. neapolitanum*, which is naturalised extensively in the south-west, it almost invariably goes by the name of *C. hederifolium* in this neighbourhood, a title which, according to Nicholson, is a synonym for *C. repandum*.—S. W. F., *South Devon*.

**Selections of Roses.**—We note your article on "Selections of Roses" (page 302), November 1. Allow us as growers for many years to add to your lists the following, which are quite first-rate, bright, floriferous, and generally desirable. To the twenty-four Teas add George Nabonnand (soft salmon), Francois Dubreuil (crimson), Mme. Chedane Guinoisean (pure yellow), Mme. Therese Levet (crimson), and Princess de Sagan (crimson); and to the twelve Chinas Eugene Beauhamais (crimson), Louis Phillippe (bright red), and a specially fine bright rosy red which may be a Polyantha hybrid—Perle des Rouges. Armosa, too, is more of a China than a Bourbon, and is a fine lilac-rose in autumn. The newer Polyantha Roses should not be omitted for bedding purposes. Gloire des Polyantha is a splendid pink, Etoile de Mai a primrose, and the lovely coppery orange Etoile d'Or and Cecile Brunner are most beautiful. Several of those you name have yet to be proved, but in the decorative Roses the Hybrid Teas Mme. Jules Grolez (soft to clear rose), Antoine Rivoire (pale flesh), and

Duc de Luxembourg (shell-pink, with white reverse) should be added. We find Edith Gifford and Rubens rather tender. Among recent climbers Ards Rover is a great gain, being of a strikingly bright crimson. We might mention that Rosa sinica Anemone, considered tender in many places, stood out with us last winter, although we had 4° below zero; it threw up from the base, and produced its lovely soft rosy flowers in profusion. The foliage of this is shining green and most elegant. Another overlooked Rose has attracted great attention—a H.P. or H.T. (?)—Zephirin Drouot, a very pretty soft and bright cherry-rose, semi-double, produced in bunches. Among the singles none have been more admired than the faint blush-whites macrantha and moschata nivea, but the Rose of 1902 with us has been most certainly Mildred Grant. Whether the blossoms are large or small they are exquisitely lovely, and stand well upright. Bessie Brown can never be popular, as she hangs her head and needs the "show wires" to exhibit her beauty, and to our mind the petals are too "papery."—GEORGE BUNYARD AND CO., *Maidstone*.

## TREES AND SHRUBS.

### THE UBIQUITOUS AMPELOPSIS.

**N**OW is the time when the Ampelopsis is in its fullest beauty. Ampelopsis Veitchii, or to take its modern and correct name *Vitis inconstans*, is one of the most useful of all hardy climbers, and the colours it is now exhibiting (late October) almost defy the pen of a scribe or the brush of an artist to depict their varied shades, ranging from palest green and yellow to deep orange and chocolate-red. In the quaint old country town near which I live the Ampelopsis has been largely planted of late years, and is rapidly covering, not only the walls of each house that owns it, but spreading across the neighbouring ones, with no apparent objection from the tenants. No one will question but that it is a thing of beauty, but I am now beginning to ask myself if it cannot be overdone—if one cannot have too much of this good thing. There is no doubt that in the town I speak of it is smothering by rapid strides the architectural beauties of some of the old houses, but then perhaps it is at the same time hiding modern architectural defects. To my mind the Ampelopsis, in order to be useful and effective, requires handling with cautious care, and by no means let it be overdone.

Were I taking a brand-new house, red brick or stucco, no doubt I should start by planting this creeper all round it, but—and here comes my word of advice, or rather suggestion—why not plant at the same time, and between the plants of Ampelopsis, some of the less rapidly growing but handsome flowering things, so that here and there as they become established an Ampelopsis may be weeded out, and thus a foliage plant make room for a flowering one. Why, for instance, neglect the beautiful hardy Clematises of which Messrs. Jackman have raised so many fascinating varieties, why not find a place here and there for a Wistaria, for one of the Passion-flowers, for the new Polyanthus baldschuanicum, and for many another flowering creeper, not least among which should rank *Magnolia conspicua*, that king of all wall shrubs. By dint of a careful selection of subjects, of which the foregoing are only haphazard instances, one may avoid the monotony which is produced from the over-use of even a beautiful thing, and ensure that variety which is always charming.

F. H. C.

### KEW NOTES.

#### INTERESTING PLANTS IN FLOWER. Temperate House.

*ACACIA LINIFOLIA*, *Calpurnia aurata*, *Camellia Thea*, *Chrysanthemum nipponicum* and various garden varieties, *Leonotis dubia*, *Podophyllum pleianthum*, and *Primula floribunda*.

#### Palm House.

*Sterculia mexicana* and *Trichilia odorata*.

#### Orchid Houses.

*Acineta Humboldtii*, *Bifrenaria Charlesworthii*, *Bulbophyllum Pechei*, *Calanthe Veitchii*, *C. vestita* var. *rubro-oculata*, *Cattleya bowringiana*, *C. dormiana*, *C. labiata*, *Cyclogne filiginea*, *Compsatia macroplectron*, *Cymbidium longifolium*, *C. tracyanum*, *Cypripedium concolor*, *C. Elinor*, *C. insigne*, *C. insigne* var. *Sanderi*, *C. Sallieri*, *C. tonsum*, *C. virens*, *Dendrobium aqueum*, *Epidendrum eustomum*, *Eria barbata*, *Laelia-Cattleya statteriana*, *Lycaste Skinneri*, *Masdevallia macrura*, *Maxillaria crassifolia*, *M. rufescens*, *Odontoglossum constrictum*, *Oncidium tigrinum*, *O. bracteatum*, *O. cheirophorum*, *O. uncinatum*, *O. varicosum*, *Pleurothallis rubens*, *P. velutina*, *Sarcanthus insectifer*, *Sophronitis cernua*, and *Stanhopea oculata*.

#### Range.

*Aloe Bowiea*, *Asarum geophilum*, *Clerodendron splendens*, *C. umbellatum*, *Crassula perforata*, *Dimorphotheca cuneata*, *Dorstenia argyrea*, *Erica conspicua*, *Jacobinia chrysostephana*, *Justicia calycotricha*, *Lindenbergia grandiflora*, *Pitcairnia Morellii*, *Ruellia amena*, *Sonerila maculata* var. *Leopoldii*, *S. Mme. E. Walter*, *S. Mme. Pynaert*, *S. Mme. Secretan*, and *S. Mme. Victor Alesch*.

#### Succulent House.

*Aloe longiloba*, *A. pluridens*, *Bomarea Carderi*, *B. pataccensis*, *Crassula rubicunda*, *Dermatobryotis Saundersiae*, and *Plectranthus purpuratus*.

#### Greenhouse.

Among other things the following are conspicuous: *Begonia Gloire de Lorraine*, *B. Mrs. Leopold Rothschild*, *Calceolaria Burbidgei*, *Carnation Mrs. Leopold Rothschild*, *Cyclamen latifolium* vars., *Eupatorium odoratum*, *Epacris* (various), *Jacobinia magnifica* var. *pohliana*, *Peristrophe speciosa*, *Schizostylis coccinea*, *Tecoma Smithii*, and *Chrysanthemums* in variety.

#### Rock Garden, Herbaceous Borders, &c.

*Campanula glomerata* var. *dahurica*, *Lithospermum prostratum*, *Iris stylosa*, *Kniphofia Hofgartneri* Ehman, *H. Cannell*, *Rudbeckia nitida*, *Schizostylis coecinea*, and *Watsonia marginata*.

### NATURAL GARDENING IN SURREY WILDS.

#### PALMS AND CAMELLIAS OUT OF DOORS.

Or the most beautiful and interesting perennials I have been able to grow successfully in the light, very dry sandy soil of the north part of Surrey, I give to *Chamaerops excelsa* the palm, but Bamboos of several kinds and Camellias come next. All have been out now winter and summer for nearly twenty years, and the Palms and Camellias have never been moved.

My largest *Chamaerops* is protected by a high hedge from the north, and has a south-east aspect. Opposite the Palm, about 20 yards distant, are some Camellias planted in a deep recess made in a Rhododendron hedge about 12 feet high. Not a ray of sun can reach these plants. They were shabby specimens 5 feet or 6 feet high, which, fifteen years ago, were removed from an old greenhouse and planted out in sand and peat. They have been in this same position fifteen years, and have flowered each year, and some years fairly well. The size and number of the flowers depends mainly on the weather from February to April. The

leaves are large and faultless, strikingly firm, strong, and healthy-looking. They shine and look as if they had been frequently cleaned, but have not been even syringed or washed in any way. Camellias evidently like shade and to grow under trees. The flower-buds for next year are now fully formed, about the size of Peas, and promise well. The finest *Chamærops excelsa* is perhaps thirty years old. It was a small table plant, no doubt grown from seed in a small pot, and was bought with a few others twenty-three or twenty-four years ago at Stevens's, and they cost a little less than sixpence each. My Palm is now 11 feet high, and the leaves extend over a space 12 feet in length, and nearly as much in width. The leaves, in all thirty in number, are well formed, and, with

of England. During winter both these natives of Japan and, I believe, parts of China look lovely, and, though forced down by accumulations of snow, rise again as soon as the thaw comes, mine without having suffered in the least even in the two hard winters we have had during the last twenty years.

It is curious that of the several Palms I have planted out—all, I believe, of the same species—the rate of growth has been very different, some having grown twice as fast as others, perhaps growing hardly at all for a few years and then starting into strong active growth. This may depend upon the water supply during the summer, but I have not lost one that I planted out in very dry places. Indeed, both Palms and Bamboos in this north part of Surrey certainly do well,

even in very dry soil, as I have proved it to be by digging down and examining it several times. In the winter we put some ordinary dry Bracken Fern round the lower part of the stems of the Palms, but the heads, leaves, and petioles have been left without any protection whatever. Even the leaves that are seven or eight years old do not as yet seem to have suffered in health or beauty.

My largest *Chamærops* is a male, and has flowered three years successively, producing three or four large bunches of very small yellow flowers, consisting almost entirely of short thick stamens. The flower-stems appear in large yellow spathes, which protrude in different parts of the circumference of the upper part of the stem in the 5 inches or 6 inches of growth of the year before the last. *Chamærops excelsa* ought certainly to be grown in many gardens near London having a south or southwest aspect. When planted it requires

little attention, but unless the gardener has had some experience in their management he should be requested to let these plants alone and try no experiments.

*Chamærops excelsa* would, I feel sure, grow well in many dells and hollows sheltered from the north and east a few miles south of London. It might be worth a trial even in Kensington Gardens. On many of the Surrey commons in natural pits and depressions, and in parts of St. George's Hills and such like pleasant places, and in dells and hollows in sandy or peaty soil, it would probably flourish. A depression in the ground some inches deep should be made near the plant, in which the rain might collect. My best specimen is on

the side of a bank looking south, which forms the back of a small shallow pit about 12 feet long and 4 feet broad, from the lower part of which I have dug a small tunnel sloping downwards in a direction under the roots of the Palm, which are very numerous and strong, and branch freely. I have no doubt that plants grown from seed and carefully hardened off when about a foot high might be obtained in numbers for experiment out of doors, but they ought not to have been forced on in hot houses. It is slow strong growth that is evidently required for plants that are to be planted out, and it will perhaps be four or five years before they move much, by which time, if left alone, vigorous growth may begin, and good, uninterrupted, steady improvement will follow.

There were fifteen or twenty years ago parts of Hampstead Heath which might have been planted if that dreadful levelling and destruction of Gorse, Broom, and other wild plants, such as Sun Dew and Buckbean, which destroyed the irregularity and natural arrangement that seems to offend some of our councillors and managers of wild woods and commons had not been ordered or decided upon. Why should not Bamboos, Rhododendrons, &c., be planted in numbers on many of our heaths? The cost would be slight, and the instruction and delight afforded to the people of all ages and classes immense. A few level places might be kept for games and gymnastics, but here and there the general area might be planted with dwarf shrubs, British and foreign wild flowers, and various plants in collections, with wide paths running between them. In a part of Regent's Park this has been already commenced, and I believe if carried out to a much greater extent in the case of many of our vacant spaces would be of the greatest advantage to, and well appreciated by, all classes. Plants would now probably seldom be ill-treated, and a keeper here and there would easily prevent interference by children and thoughtless people. Indeed, the time is near when the public will themselves protect vegetation, and our commons and plantations would be no more interfered with or injured than are the thousands of private suburban gardens in and around London.

North Surrey.

F. R. C. P.

## CHrysanthemums.

### THE BEST TWENTY-SIX EARLY-FLOWERING VARIETIES.

F undoubted merit are the following:

#### JAPANESE.

*Mme. Marie Masse.*—As this variety is an ideal border plant, it should certainly head the list.

It is a plant of sturdy growth and branching habit, and bears in prodigal profusion pretty blossoms, and each on a good length of foot-stalk; colour lilac-mauve, which, under certain conditions, deepens into a rose-pink; height about 2½ feet; comes into flower in the latter part of August and continues well into October.

*Crimson Mme. Masse.*—This is really a chestnut-coloured sport from *Mme. Marie Masse*, and as the flowers age they pass to a deep rich bronze. In other respects its characteristics are identical with the parent plant, and this beautiful sport may be considered a splendid addition to the early sorts.

*Ralph Curtis.*—Another sport from *Mme. Marie Masse*, and a plant which appears to be comparatively unknown. It is one of the most robust members of this family, and blooms most profusely; colour creamy white, and, under certain

CHAMÆROPS EXCELSA IN A NORTH SURREY GARDEN.

(This Palm has been growing out of doors for twenty years.)

the exception of three or four of the oldest, are not ragged or damaged by weather. The largest are 4 feet in diameter, and the petiole is of the same length. The hairy stem is 5 feet high and nearly 3 feet in circumference. I find that transplanting Palms throws them back for two years or more. A good place should be chosen at first, and even if the plant should look a little unhappy and show no growth it is better to leave it alone, as after a year or two it will probably improve and then throw new leaves and steadily grow without ceasing even in the winter.

*Chamærops excelsa* and Bamboos contrast remarkably with most of the shrubs and plants we are able to grow in our gardens in this part

little attention, but unless the gardener has had some experience in their management he should be requested to let these plants alone and try no experiments.

*Chamærops excelsa* would, I feel sure, grow well in many dells and hollows sheltered from the north and east a few miles south of London. It might be worth a trial even in Kensington Gardens. On many of the Surrey commons in natural pits and depressions, and in parts of St. George's Hills and such like pleasant places, and in dells and hollows in sandy or peaty soil, it would probably flourish. A depression in the ground some inches deep should be made near the plant, in which the rain might collect. My best specimen is on

conditions, the bases of the florets are slightly suffused a salmon colour; height, season of flowering, and other characteristics identical with the parent plant.

*Robbie Burns.*—In this instance we have a rosé cerise sport from Mme. Marie Massé, and quite distinct from all others. This variety is very charming in its earlier stages of flowering, the colour of the blossoms at that period being distinctly pleasing. Its period of flowering appears to be a week or ten days earlier than that of other members of this group of Chrysanthemums, but with this exception there is no difference.

*Horace Martin.* This is the latest addition to the sports of Mme. Marie Massé, and probably the most valuable of the whole set of five sorts. The colour is a deep rich yellow, and in certain districts is slightly suffused a shade of bronzy crimson at the base of the florets. In so far as regards habit, freedom of flowering, height, and constitution it is quite equal to the other four sorts. The distributor of this sport grew no less than 60,000 of this variety in the season which has just closed, and this should be sufficient to prove its high value.

*Mme. Casimir Perier.*—A Continental introduction of some ten years' standing, it is a plant with a wonderfully good branching habit of growth, developing a very free display of good blooms of even and pleasing form, and each one on a capital length of foot-stalk; colour creamy white, tinted pink; height about 2½ feet to 3 feet; in flower in August and September.

*Gaucher's Crimson.*—An excellent addition to the early-flowering section, though very similar to a Continental introduction named M. J. Bte. Chauvin. The colour is a bright rich crimson, with a golden-bronze reverse, and the flowers, which are large and borne on stout erect foot-stalks, make a bold show of a useful colour in the hardy flower border; height slightly over 2½ feet; period of flowering late September and October.

*François Vuillermet.*—Although this variety has been in commerce for several years, it is a plant that has not been grown so largely as its merits deserve. Its habit is beautifully branching, and its height does not exceed 2 feet. The blooms are fairly large and full, and each one is borne on a useful length of stout foot-stalk; colour lilac-pink; in flower during the latter half of September and October.

*Doris Peto.*—This is a pure white sort of English origin, and little has yet been seen of it. The form of the dainty and pretty flowers is ideal, and as in this respect it equals Mychett White, and the plant has as good a constitution as Market White, this comparatively new variety may be regarded with favour; height about 2 feet; in flower September and early October.

*Leonard Peto.*—One of the most striking bright and rich yellow earlies in commerce, being a veritable mass of beautiful blossoms, which are most profusely developed. But for the advent of Horace Martin this plant would have created a great impression, as it produces a large and compact yet graceful head of flowers, and each one speaks for itself; height about 3 feet; in flower during September.

*Lemon Queen.*—This is one of the earlier raised English seedlings, and there is much to admire in it. Its colour is a rich orange-yellow, and the form of the flowers is pleasing; florets rather narrow and slightly drooping; habit branching and sturdy; height rather more than 3½ feet; in flower during the latter half of September and October.

*Harvest Home.*—A bright and rich crimson flower, with a golden reverse also tipped golden-yellow, and a plant which has been highly thought of for some years; habit fairly branching and sturdy; each flower is borne on a strong, erect foot-stalk, and in consequence each one can be utilised; height about 3 feet; in flower during late September and October.

*Market White.*—A very pretty pure white, but hardly so pleasing as Mychett White in form, having somewhat broader florets. The plant is sturdy and branching, and comes into flower in

late September and continues blooming throughout October; height about 2½ feet.

*Norbert Puritz.*—A Continental introduction of more than ten years ago, and, except in a few instances here and there about the country, rarely seen. Its colour is a striking rich golden-salmon, the cut blooms under artificial light being very rich and effective. The flowers are of good size, and are developed on plants less than 2 feet high; period of flowering September and early October.

*Orange Massé.* This must not be confounded with the family of plants represented by Mme. Marie Massé and its sports. The form of the flowers is quite distinct, and the habit of the plant is taller and somewhat straggling. Nevertheless, it is a very excellent plant, bearing in great profusion charming sprays of blossoms of a pleasing bright bronzy fawn colour. In my own garden the plants exceed 3½ feet in height; period of flowering late September and October.

*Rycroft Pink.*—One of the most dainty early sorts. The flowers are not large, but their form is very pleasing, and when cut in sprays as they are naturally produced they make valuable decorative material, and the blossoms are borne in great profusion, colour bright pink; height about 18 inches or rather more; in flower in September and early October.

*Notaire Groz.*—This is a very refined kind, developing elegant sprays of beautiful silvery-mauve blossoms of high decorative quality; height about 4 feet, rather straggling habit, and a profuse bloomer; period of flowering the whole of October.

*Bouquet de Feu.*—A very useful plant of a sturdy and dwarf character, developing rather small blossoms with notched florets; colour a pleasing shade of light bronzy terra-cotta; height rather less than 2 feet; in flower at end of September and throughout October.

*Chateau St. Victor.*—This is a plant of easy culture, developing pretty flowers of a pleasing shade of amaranth quite freely; habit fairly bushy and branching; height about 3 feet; in flower during the whole of September and early October.

*Bronze Prince.*—An English-raised seedling of an unique colour, which may be described as old gold, shaded cherry-carmine, with a golden-bronze reverse; florets flat and not over long, and rather pointed; the plant has a slender habit, but is very free flowering; height about 3 feet; in flower during September and the first half of October.

*Ivy Stark.*—This is an excellent representative of the early sorts, and may be described as an early Source d'Or, which variety it very much resembles: colour rich orange-yellow; height about 2 feet; period of flowering, September and the earlier half of October.

*Irene Huit.*—A very beautiful, free-flowering plant, much admired at the Tamworth trial of early sorts. The florets are long and somewhat twisted, and build up a charming Japanese bloom. The colour may be described as golden-chestnut, and this is very effective in the garden: height about 3½ feet; in flower latter half of September and October.

*Mychett Pink.*—This is one of the earliest of the Japanese sorts to flower, and may be had in August and September in pleasing form. The earliest flowers are white, slightly tinted blush, but those developing later in the cooler weather are of a soft pink colour; habit branching and sturdy; height about 2 feet; propagation late in the spring suits this variety admirably.

*Dorothy King.*—A novelty which has much to commend it. The flowers are large and full, and develop in good bunches; colour a pleasing shade of deep pink, striped light pink; height about 2 feet; period of flowering late September and October.

*Henri Yoon.*—A sport from M. G. Grunerwalde, and one of the most reliable of the members of that group of Chrysanthemums; the colour is rosy salmon on a yellowish ground, and the flowers are large and full. The plant commences to flower in early August and blooms continuously till October; height about 18 inches.

*Mme. Guindudeau.*—This plant has a good reputation, and blooms most profusely during the latter half of September and October; colour pink on a white ground; habit bushy and spreading; height about 2½ feet.

All the above varieties are in commerce, and any Chrysanthemum specialist should be able to supply them.

*Highgate, N.*

D. B. CRANE.

## NOTES FROM SCOTLAND.

THE advent of November finds many of our Scottish gardens still comparatively bright with flowers long since past in England. One hears of such things as Rudbeckia speciosa, Salviyas, Linaria bipartita, Fuchsias, Gladioli, French Marigolds, Dahlias, Sweet Peas, Hollyhocks, and, of course, Asteris still beautifying gardens, not only in warm positions but in very late, cold districts, as at Drumlanrig for instance, where Mr. Inglis is still cutting Carnations, &c., from the open. Here at present Sutton's Rose Queen Hollyhock, of which we have two large masses, is quite brilliant. Raised from seeds it comes true to colour, which approaches more nearly to red than rose. It is marvellous how many flowers that ought to be common to every garden are scarcely known at all. Linaria bipartita is one such, and numerous have been the enquiries as to the identity of this pretty annual. Schizostylis coccinea is another, which invariably when in flower—as it has been for some time—calls for much questioning. Then I should imagine Erigeron mucronatus and Aster Linosyris are very seldom prominently planted in gardens, or perhaps our cooler climate suits them better than the warmer south.

One class of plants has been rather disappointing all this dull season, namely, the fibrous-rooted Begonias. They have been quite smothered with coloured buds, but, unfortunately, few of these have expanded, and as a consequence they have done nothing to brighten the garden. On the other hand, single tuberous Begonias, though late, have made a glorious bit of colouring. I made bold this year to plant directly into the beds tubers that had been merely started, and these, notwithstanding the backward character of the season throughout, have been most satisfactory. Sweet Peas, as I have already remarked, are abundantly in flower, and this may be interesting to those who fail with plants raised from seeds sown in heat in January; those grown in a cool structure till planted out are still producing flowers profusely. This is the case not only here, but in other gardens far apart.

### MICHAELMAS DAISIES

in some respects have been disappointing, because in all parts of the country many have not yet reached the blooming stage. Here, where they come somewhat early, Aster Tradescanti is just showing one or two of its pretty white flowers, and the later varieties of A. Novae-Angliae will not flower at all. I hear of such fine old kinds as A. Amellus and A. ericoides not flowering, so it is clear that to enjoy the harvest of Michaelmas Daisies only the earlier sorts should be selected. Fortunately, these are sufficiently numerous. I plant annually a large number of bulbs of Galtonia candicans. This year many hundreds have died without any apparent reason, and there has on that account been a regrettable blank in the garden. But it has not been here alone that the plants have died out, as I have heard of the same occurrence elsewhere. Montbretias also, and especially M. rosea, have shown like symptoms of ill-health—a most regrettable circumstance.

I understand a new Scottish journal on the lines of *The Field* is to make its appearance in the new year under the name of *The Scottish Field*. It will appear only once a month, and, while catering for those who are fond of sports and other forms of enjoyment and employment in the country, gardening from a purely Scottish point of view is not to be neglected. The headquarters of this new journal will be in Glasgow.

### THE NURSERY TRADE.

Material for planting as grown in the Edinburgh

nurseries is in splendid condition this year, but somewhat late in maturing. While inspecting one of the larger establishments the other day it was a pleasure to see the great blocks of some particular forest tree in tens of thousands, as good in size and quality as if each one had been specially prepared, and, more remarkable still, nothing was there beyond a saleable size; this is a vast improvement on the state of the trade ten or twelve years ago.

Prestonkirk.

## THE ROSE GARDEN.

### ROSE LADY EMILY PEEL.

**O**NE would not think that with the many varieties available old kinds such as the above would still be sought after. But so it is. Lacharme was a good judge of Roses, and he would not have sent out this variety, even 40 years ago, had he not been convinced of its value. Lady Emily Peel is a vigorous grower, as are most of the hybrid Noisettes, and it blossoms well in the autumn. The flowers are of fair size, white faintly shaded rose-pink. We should like to see the whole of the Noisette Perpetuals retained in our collections. What can be more lovely than Mme. Anguste Perrin, Mme. Fanny de Forest, Mme. Alfred de Rougemont, Mme. Blanche Durrschmidt, and such like during autumn.

### THE PERGOLA IN ENGLISH GARDENS.

By Miss JEKYLL, V.M.H.

(Continued from page 327.)

THE height and width of the pergola and the width apart of the pairs of piers can only be rightly estimated by a consideration of the proportions of other near portions of the garden, so that it is only possible to suggest a kind of average size for general use. The posts or piers should stand from 7 feet 2 inches to 8 feet out of the ground when the piers stand from 8 feet to 9 feet apart across the path. In a garden where there is nothing very high close by, this kind of proportion, rather wider than high, will be likely to be the most suitable; but there may be circumstances, such as a walk through a kitchen garden, where economy of space is desired, or when the pergola has to pass between tall trees at a little distance to right and left, when the proportion that is rather taller than wide had best be used. In a whole or covered pergola the pairs of piers would be further apart in the length of the walk than between the individuals of each pair *across* the walk, but in the open pergola, where there is no roof and either no connexion or only garlands and level side rails—or garlands alone—they may stand closer.

For the open pergola without top Roses are among the best of plants; on one post a pillar Rose and on the other a rambler. A select list for this use would be: As pillars, Alister Stella Gray, nankeen yellow; Reine Marie Henriette, red; Climbing Aimée Vibert, white; Carmine Pillar and Waltham Climber, No. 1, reds; and for ramblers, the Garland, Dundee Rambler, Bennett's Seedling, and Mme. Alfred Carrière, all white or flesh white; Crimson Rambler, Reine Olga de Wurtemberg, Longworth Rambler, and Dawson, reds; as well as multiflora single and double, the large-flowered multiflora, and R. Brunonii. To keep the bases of the piers clothed some strong young shoots of the current year should be shortened

so as best to cover the space, when, instead of making the whole length they would otherwise have attained, they will stop growing at the tips and throw their strength into preparation for flowering shoots at the lower levels.

Among some others of the best plants for the open pergola are the free Japan Honeysuckle, the common but always delightful white Jasmin, the new *Polygonum baldschuanicum*, *Clematis Flammula*, the little-known but quite excellent *Clematis paniculata*, blooming in October, the large-flowered Clematis, late Dutch Honeysuckle, *Crataegus Pyracantha*, *Rhodotypos kerrioides*, *Kerria japonica*, double-flowered Brambles, and *Forsythia suspensa*.

There is another class of shady covered way made of flowering trees that differs from the pergola in that when mature it has no adventitious supports whatever, the structure being formed by the trees themselves. It may be of shade trees only, when it comes near the pleached alleys of our ancestors. For this the best trees are Plane, Hornbeam, Wych Elm, and Beech. The Planes should be planted 10 feet to 12 feet apart, and pollarded at 8 feet from the ground; their after-growth is then trained down to a temporary roofing framework of poles. In the case of this tree the sides are open. Hornbeam, Wych Elm, and Beech are trained as they grow to form both walls and roof. But many of the small flowering trees do very well trained as flowering shady ways, though when they have arched over and form a complete roof the flowers are mostly on the outer sides. One of the best for this use is Laburnum, but the beautiful Japanese flowering Apple (*Pyrus Malus floribunda*), the Snowy Mespilus, the Guelder Rose, the Siberian

and other fruiting Crabs, are all amenable to the same treatment. This leads naturally to covered ways of other fruit trees, and the delights of the fruit garden are much increased by the presence of a naturally formed pergola of Apple, Pear, Plum, Medlar, and Quince trees.

Some adaptation of the pergola, of a temporary kind, is also extremely useful in the case of a garden that is new and raw, or in some place that is held on a short tenancy, when the tenant wishes to enjoy shade without having to wait for the growth of long-lived and slow-growing plants. Any poles, from the Hop-pole to the Bean-pole size, put up as the framework of a covered way, can in one season

be clothed with a grand growth of the great Orange Gourds, the *Potiron rouge* of our French neighbours. These, with others of the ornamental Gourds and quick-growing climbers, such as Japanese Hop, Major Convolvulus, *Mina lobata*, Canary Creeper, and the trailing Nasturtiums, will give ample shade in the hottest months and a glory of autumn fruit and bloom. Plants that are suitable for the open pergola are equally suitable for verandahs, with the addition of some others of the tenderer kinds that will succeed in the shelter and warmth of the sunny house-front, especially in the southern counties. For here we may have, as in Devonshire, Cornwall, and the Isle of Wight, Fuchsia, Myrtle, Pomegranate, *Solanum jasminoides*, and *Solanum*

AN OLD GARDEN ROSE: LADY EMILY PEEL.

crispum, and even a little further north the beautiful *Bignonia radicans* and the blue Passion-flower. Perhaps a well-grown *Wistaria* is the best of all verandah plants, for not only does it yield its masses of bloom almost unfailingly year after year, but its foliage is both graceful and handsome, and always looks fresh and clean.

It is well to think out various combinations for verandah planting that will give a good succession of flower. Thus, as one example, the season of bloom might begin with *Wistaria*, or *Robinia hispida*, a capital shrub for this use; then in full summer would come white Jasmine, and, later, *Bignonia radicans*. *Wistaria*, if allowed to grow at will, covers a very

A DRY WALL, SHOWING IRREGULAR JOINTS FILLED WITH SOIL (NO MORTAR USED).

large space, but if rather closely pruned it can be kept within bounds and flowers with astonishing freedom.

The Ayrshire and rambling Roses are beautiful in their season on a verandah, but they have the disadvantage of being for one season only, and they cover so much space that but little room is left for any other plants.

## WALL GARDENING.

### MAKING A WALL GARDEN.

#### II.—VARIOUS WALLS AND THEIR POSSIBILITIES.

**W**ALLS, generally speaking, may be divided into two great classes, namely, dry walls, i.e., built without cement or mortar, and masonry walls, which have the stones more evenly placed and the joints filled with cement or mortar.

##### DRY WALLS.

A good example of dry walling is given in the accompanying illustration. It will be seen that there is regularity only in the top row of stones. Although the face of the wall is almost perfectly flat, without any projecting stones, the joints are uneven and irregular. It will be readily seen that for the purpose of wall gardening such a method of placing the stones has great advantages, as the joints would admit the use of plants varying considerably in size, and also in the root space they may require, as naturally the largest and deepest joints would be filled with the boldest kinds of plants. In a subsequent chapter on this subject I hope to give sketches showing sections of various walls.

In all dry walls, regular or irregular, the stones should be tilted backwards to allow the rain water to soak in between the joints, where the slightly sloping stones would carry the water

backwards into the soil. If the stones do not naturally lend themselves to being tipped backwards in the manner described, the desired effect may be obtained by inserting small wedge-shaped stones, which would not only tilt the stone and make it more secure, but would also increase the width of the joint and make the latter available for more soil. The illustration shows several such instances of small stones introduced for that purpose.

Dry walls as a rule have only one face, and are built up against ground which falls abruptly, so that they form retaining walls which, without doubt, are the best for the purposes of wall gardening. If, however, such dry wall was built standing quite free, forming a sort of boundary wall either of the garden itself or some portion thereof, it would be best to have it sufficiently thick to prevent the soil in its interior from drying up too rapidly during a spell of hot dry weather. Sometimes very pretty effects of planting may be had on walls of that description which mark the boundary perhaps of a formal garden, separating the latter from other portions of the ground. More especially is this the case when these walls need not be built sufficiently high to form a protection against cattle, &c., but divide merely different parts of the garden itself, where they could be kept so low that the eye would look down upon, and not up to, the plants on the top. A good proportion would be a thickness of, say,  $2\frac{1}{2}$  feet and a height of 3 feet to 4 feet. Walls of that kind possess the advantage of enabling us to grow plants requiring shade as well as those requiring a sunny position on the same wall, and sometimes both the shady and the sunny side may be seen at the same time.

Another kind of dry wall suitable for wall gardening may consist of a sunk fence dividing, say, the pleasure grounds from a park, meadow, or grass field. If the ground of the adjoining land should be fairly level or sloping towards the garden or pleasure grounds then the sunk fence would not be suitable for wall gardening, because the additional railing or other fencing required to keep off sheep or cattle from the plants in the wall would be clearly visible from the garden, or perhaps even from the house.

But if, as is often the case, the pasture land slopes rapidly in the opposite direction, i.e., away from the house, it is generally possible to have the dry wall which forms the sunk fence of such a height that a border, a path, and also a fence of some kind at a distance of, say, 5 feet or 6 feet from the dry wall would still be invisible from the house and from the garden. Thus the dry wall may be turned to good account for wall gardening without the danger of being molested by cattle and without bringing a hard dividing line conspicuously into view. Still another kind of dry walling suitable occasionally for wall gardening would be the ordinary stone hedges which are so abundant, especially in the West and North of England. If such a hedge forms the boundary, say, of a small garden abutting against a road or field, there is no reason why the garden side of such a hedge, whether sunny or shady, should not be turned into a beautiful wall garden, made bright and cheerful by flowers of many sorts.

But the most important of all kinds of dry walls is the terrace wall. It is here that wall gardening should be at its best, because the conspicuous position of a terrace wall will make it imperative that it shall be adorned as much as possible with suitable plants. Even terrace steps may often be constructed on the dry wall principle, and very ornamental they may be made with tiny plants protruding from every chink or fissure. It is wise as a rule to build dry walls for wall gardening, not too high, so that the plants with which the wall is furnished may be, if possible, never much above the average level of the human eye. If the ground falls rapidly it would be better to have several successive terraces rather than a dry wall of considerable height, unless the terrace wall is a masonry wall, intended not so much for the purpose of growing plants on the wall itself as for being covered with ornamental creepers. In such a case, of course a higher wall might be desirable and often practical. As detailed construction of the various kinds of dry walls will be illustrated in a later essay I will now briefly deal with the other class of walls, namely,

##### WALLS OF MASONRY.

By walls of masonry are meant walls in which the stones or bricks are placed regularly and are held together by cement or mortar of some kind. It must not be supposed that such walls are entirely unfitted for wall gardening. On the contrary, they may often be made very ornamental indeed, but it takes longer as a rule to get the plants established, as in most cases these have to be reared from seeds sown on moss and soil pressed into the joints after a portion of the mortar has been removed. Sometimes, too, it is possible without doing great damage to remove a few stones here and there and make holes large enough to hold the soil. The task of establishing plants on a masonry wall is much easier if the latter should be several years old (the older the better), and if it should already be partly covered with moss or other vegetation.

Where such walls of masonry are deep, terrace walls, say, near a large mansion, or where they are crowned with balustrading or other architectural features of importance, which in design correspond with the style of the architecture of the house and are probably built with stone elaborately worked, it would be a mistake to knock holes in them, and it would probably be much better to cover them with handsome climbers rather than small rock plants which on high walls of that kind would be out of place, and too far away from the eye to be fully appreciated, while Roses and other bright flowering creepers, both deciduous and evergreen, would be far more satisfactory and produce a better effect.

Elmside, Exeter.

F. W. MEYER.

(To be continued.)

## NOTES ON HARDY PLANTS

### POLYGONUM LANIGERUM.

**A**LTHOUGH only about twelve years have passed since this plant was first brought to notice through the agency of the St. Petersburg Botanic Garden, it has been largely used for outdoor decorative planting in summer. It is found widely distributed about the tropics and sub-tropics, but is not met with in Europe. Although in some descriptions it is stated to be a perennial, it is usually treated as an annual, and it is doubtful whether it would live through a severe frost. It varies in height from 4 feet to 10 feet, the stems being stout, fleshy, and semi-procumbent. Side branches are numerous, and strong plants growing in rich soil are sometimes found as much as 5 feet through. The flowers are in terminal heads and red, though it is not often that they are seen. The chief beauty of the plant lies in its large, handsome foliage, which is of a silvery hue by reason of a dense, silky tomentum. The individual leaves vary greatly in size, the larger ones being almost 12 inches long and 4 inches wide. Where sub-tropical bedding is practised this Polygonum will be found most useful. It makes a handsome bed in a prominent position on the lawn, while as a group in the herbaceous border its distinct appearance and colouring are very striking. By sowing the seeds indoors early in spring, and so having strong plants to plant out in May or early in June, the best results are obtained.

W. D.

### NOTES FROM DEVONSHIRE.

AT this period of the year very varied notes on the abnormal flowering or fruiting of certain plants usually appear in numerous journals, local and otherwise; this season writers have had abundant material, owing to the erratic weather which has prevailed throughout the whole year. The advent, however, of a few warm days, accompanied by some hours of bright sunshine during the latter part of October and the few days that we have already experienced in November, has induced vegetation in this part of Devon, whether wild or in the garden, to retain what should have been its summer garb, and this, together with the simultaneous appearance of many autumn flowers in their proper season, is giving us a sort of combined summer and winter flora. In the hedges the Periwinkle and Lychnis are bright with their blue and red flowers, while close beside them is the wild Strawberry, both in flower and fruit, and the black and pretty ripe fruits of the Blackberry jotted about in big clusters, and sometimes crowning the hedge itself with huge black masses. The scarcity of sunshine at the right season to ripen the berries properly has made the crop a late one, and the prevailing rains have, to a large extent, washed out the flavour. In contrast to the Blackberries, in many localities the hedges are crowded with the large white fruits of the Snowberry (*Symporicarpus racemosus*), which is especially abundant in this neighbourhood.

To come to the garden, things have been somewhat provoking, especially with summer Roses. Many of them, however, are now making up for these shortcomings, especially Alister Stella Gray, which is now full of flowers and has plenty of buds. Amongst other plants still flowering in sufficient abundance

to provide cut flowers for my rooms are Sweet Peas, *Lavatera trimestris*, *Godetia*, Lady Albermarle, *Phlox Drummondii*, Chinese Pink, Dahlias, *Nicotiana affinis*, *Mignonette*, *Nasturtiums*, Marigolds, Honeysuckle, White Jessamine, and *Laurus*-*tinus*.

JOHN R. JACKSON.

*Clarendon, Lympstone, South Devon.*

### PRIMULA CAPITATA.

THOUGH autumn is always laden with "unwelcome lore," as the poet called it, for the flower-lover, yet it has its compensations as well, and one of these is that we have time to linger longer over each individual plant to study its beauties, often heightened by the attributes of the time of the year. Such is one's thought as one studies *Primula capitata*, now blooming so prettily by the margin of a little Water Lily pool. Earlier in the year we seem to care less for its fine heads of deep purple flowers, but now, when flowers grow scarcer and there are fewer of bright colours, we seem to enjoy all the more this late-blooming species. It is most attractive indeed, for one cannot but admire its colouring and the beauty of the individual blooms, congregated in a close head, and, when looked at in various lights, showing some beautiful tints. Unfortunately, it is not a long-lived plant as a rule, and the advice given in "The Century Book of Gardening," to raise it frequently from seed, is highly necessary. In stiffer soil than mine it appears to resent much moisture at the roots in winter, though it must have plenty all the summer through. Here, however, it does not object to having moisture at the roots in winter as well and thrives in as wet a spot as *P. japonica*. This autumn appears to be giving us an unusual number of late flowers on the various *Primulas*, and double and single *Primroses* and *Polyanthuses* also are blooming more freely than is their wont at this time. None among them is more admired than the Himalayan *P. capitata*.

S. ARNOTT.

### COTONEASTER HORIZONTALIS.

THIS beautiful Cotoneaster is one of the prettiest and most acceptable of small shrubs, of such dwarf stature as to be eminently suitable for growing on small rockeries or in the alpine gardens of smaller size than those in which the larger species can be planted with advantage. It is true that some

think that its deciduous habit makes it less valuable than such species as *C. thymæfolia*, but no other species of its size has its elegant though, in a sense, formal habit of growth, which never fails to attract attention and to make it appreciated. When it is allowed to form a large plant, covering a little space on the rockwork, it is particularly handsome; but even in a small state it is full of charm with its fan-like branch arrangement. It is one of the freest of all to fruit, and in this garden, where few of the others fruit well, *C. horizontalis* is well berried and is very pleasing indeed, with its bright scarlet bead-like berries showing against the dark green small leaves. Many of these leaves will become bright red before they fall for the winter. The flowers, which are, of course, freely produced to give such a crop of berries, are rosy coloured and come in spring, so that the little shrub is possessed of more than one or two merits to commend it to our favour. It looks well against a large stone on one of the flanks of the rockery, or even filling a large pocket in a more formal rockery built for cultural rather than artistic requirements. It comes from China, whence it was introduced in 1879, and is perfectly hardy with us in Scotland. I know of its doing well in much colder localities than this.

S. ARNOTT.

### ACAENA BUCHANANI.

WE owe all our garden Acænas to the Southern Hemisphere, and of those in cultivation all but a few are natives of New Zealand, the native habitat of the one now under notice. The most useful of the genus belonging to the section composed of those which creep close to the surface of the soil, and form what we may call perfect carpeters. A few of the genus assume a more upright habit, and are not so suitable for carpeting the dwarfer bulbs as the others, though they are, it may be, equally attractive in themselves. It is to the creeping section that *A. Buchanani* belongs, and no one who knows it will question its claim to be considered one of the most precious of its class. This is true, despite the fact that it has not the crimson spines of *A. microphylla*, which give that plant a greater share of bright colouring. On the other hand, *A. Buchanani* has very beautiful small foliage, much the same in size and character as that of *A. microphylla*, but of a most charming pea-green. It is

A BED OF POLYGONUM LANIGERUM IN THE ROYAL GARDENS, KEW.

very beautiful indeed, and I have never regretted making its acquaintance several years ago in one of the prettiest and best of our large British botanic gardens. The flowers are greenish and of no value, and the "burrs," or little round heads, are of the same colour as the pretty pinnate leaves. Like the greater number of the genus, it is not fastidious as to soil or situation, but its likings are best supplied by giving it a moist and half or wholly shaded position in a peaty soil.

It is a capital plant for planting about the rough stone steps of the alpine garden, and it makes a splendid carpeter for Snowdrops, Snowflakes, *Colchicums*, Tulips, and the like, as well as for the taller herbaceous plants. Although it is not a plentiful plant in the nursery trade, it is in the hands of some of the hardy plant dealers, and will soon be much more plentiful. It is very easily propagated by division, cuttings, or seeds. I prefer spring planting for this species. Under the name of *A. berteriana* I received a plant from New Zealand bearing a very close resemblance to *A. Buchanani*. So close, indeed, was the resemblance that I remarked upon it to the sender, who informed me that he had received it from a competent botanist. Since my plant has grown larger I am inclined to think that a small difference exists, and that the one received as *A. berteriana* has lighter green foliage. It is apparently quite as good as *A. Buchanani*, as I have known it for some years.

S. ARNOTT.

long, arching, gracefully disposed leaves, is at all seasons decidedly ornamental, but in early autumn, when overtopped with its silvery plumes, there is then nothing to compare with it. Besides the ordinary form there is a variety with variegated leaves, and another in which the flower panicles are pinkish. This variety, known as *Rendatleri*, is not so beautiful as the type, but from its distinct appearance it is well worth a place in most gardens. In the South of England the Pampas Grass is hardy, but in more northern districts it cannot be thoroughly

garden picture! Is it not possible that the secret might be summed up in the one word "reflection?" Many a time have I longed to point out to the owner of a despised pond, in some cases not a stone's throw from the house, that the whole aspect of the place might be changed were the water's edge but fringed with colour, and endless possibilities would present themselves for beautifying such a spot if the same principles which govern the arrangement of colour in the flower garden were followed. It is to put into practice this theory rather

than to create a water garden, in the strict sense of the term, which we have tried at Broughton, where the moat completely encircles the castle and garden.

I have already explained in a previous article that with us the prevalence of severe frost limits our selection of plants, but there are so many effective substitutes for the rarer species, amongst the thoroughly hardy kinds adapted to the wild garden, that resignation is an easy matter. If the planting of the water's edge is to form a feature from any given point, I think it is im-

portant that the massing of colour should be on the farther side, so that none of the beauty of reflection should be lost. To obtain this effect we group our Water Lilies, Arums, and other low-growing plants in the foreground, thus ensuring an uninterrupted view of the Shirley Poppies which play an important part in the colour scheme, and know of no more lovely picture than a succession of these (for we sow in autumn as well as spring) mingled with tall white Foxgloves, and the great flowering heads of the giant Hemlock towering above them. When the Poppies are a thing of the past, the pink Mallow will be found an excellent substitute. Hard by, amidst the tangle of *Rosa rugosa* and Briars, a gleam of vivid blue—a very carpet of the wild Geranium—forms a daring contrast, and there in semi-shadow the tall rose-coloured blossoming shoot of the bronze-leaved Rheum (which, to my joy, flowered last summer) has run a race with the giant Fennel as to which should succeed in casting the longest reflection on the surface of the still water. Delphiniums, flanked on either side by *Lilium croceum*, *Spiraea Aruncus*, the erect *Spiraea gigantea*, and the lovely rose-red *Spiraea palmata*, their toes virtually in the water (the latter rewarding us last summer for the protection we gave it during the spring frosts by an unusual number of flower spikes), *Arundo Donax*, and the great leathery leaves of the Gunneras, all mingle on the bank, to say nothing of the common Rhubarb, one of the

A GROUP OF PAMPAS GRASS (*GYNERIUM ARGENTEUM*), SHOWING ITS BEAUTY IN THE AUTUMN.

(The photograph was taken October 30.)

depended upon unless protected. The New Zealand *Arundo conspicua* (now *Cortaderia conspicua*), though less imposing, is harder than the Pampas Grass, and may therefore be planted in colder localities. Even this is, however, in many places benefited by a certain amount of protection. Both the above-named prefer a good deep soil with ample supplies of water during the growing season, but stagnant moisture in winter is injurious."

#### WINTER SCHEMES FOR SUMMER COLOURING.

[Reproduced by permission from "Country Life."]

FROM the foothills of the Rocky Mountains to my water garden at Broughton seems a far cry indeed; but with a cloudless sky overhead, and the thermometer standing at 108° in the sun, it is not difficult to transport one's self in thought to the peacefulness of an English summer, even though the New Year is but seven days old, and the peaks of the great range, stretched out before one's eyes, are capped with winter snows.

I have often wondered wherein lies the undoubted charm of water in a landscape. It is not the boundless sea, with all its human restlessness, that I have in mind when endeavouring to solve this problem, but rather the humbler stream, or lake, or pond, possibly not beautiful in themselves, yet when fringed by plants and flowers how precious in the

## THE FLOWER GARDEN.

### PAMPAS GRASS.

**F**EW hardy plants are more imposing and handsome at this time of year than *Gynerium argenteum*, popularly called the Pampas Grass. Our illustration will give a good idea of its value and beauty as a lawn plant when boldly grouped; for planting at the edge of woodland or shrubbery, where its waving silvery plumes stand out strikingly against the dark background, it is hardly surpassed. In our issue of November 1 particulars of this plant were given, which it may be interesting to recall: "For some years subsequent to its introduction in 1848 this was botanically known and still is generally met with in gardens as *Gynerium argenteum*, but now we believe it is correctly called *Cortaderia argentea*. Differences of opinion may exist as to the necessity for changing the name after it has once become thoroughly fixed, but its great beauty at this season of the year affords no food for controversy, for it is in its way unapproachable. A good healthy tuft, with its

most valuable plants for bold effects I know. There is a tall-growing and exceedingly graceful *Seabious*, whose full botanical name I cannot recall to mind at this moment, which seems to love the moisture, and whose lemon-tinted flowers, rising from a carpet of the large blue *Forget-me-not*, form a charming contrast.

Great masses of *Epilobium* and *Lythrum roseum* are also valuable in a suitable position; but the touch of magenta in both makes it sometimes a little difficult to place them. The common *Artichoke* I also find provides a charming cool grey note, and is particularly effective when grouped with *Tritomas*, or the early *Sunflowers*. The *Polygonums* are useful if they can be kept within bounds, but they spread with an amazing rapidity; nor must I forget the *Irises*, notably the tall yellow flag which grows in profusion when planted in the water. *Iris gigantea* prefers a drier spot on the bank. *Iris Kämpferi*, alas! we have tried and found wanting; and this has been one of my keenest disappointments in the making of the garden, for it is a very human failing that the heart's desire is for ever set on the unattainable. Having tried it in sunshine and in shadow, in semi-moisture and in a dry position on the bank, the result has always been the same—a few magnificent blooms the first summer, and then a gradual dwindling away, a sickly appearance amidst uncongenial surroundings.

Personally, I am of opinion that it is the lime in our soil which is the arch enemy of the *Kämpferi Iris*, and in this I find I have the concurrence of no less an authority than Mr. Freeman Mitford, whose experience under similar conditions has been the same as mine.

Mr. Wilson, however, who was so successful with this beautiful species at Wisley, did not altogether share our view, and if any reader can throw further light on the question, such information will be most acceptable. It is unnecessary for me to dwell at any length on those invaluable additions to our water gardens—the hardy, coloured *Nymphaeas*. They have taken kindly to the rich loam in the moat, and are now thoroughly established. Those I have found most satisfactory are *N. chromatella*, *N. sulphurea*, *N. carnea*, *N. Laydekeri rubra* and *Laydekeri rosea*, *N. ellisiana*, and the American variety *William Falconer*. These were all sunk in open hampers during April or May in 12 inches to 18 inches of water, the flowers reminding one of gorgeous jewels as they lie gleaming in the sun.

Shall we ever be given what all lovers of the *Nymphaeas* are anxiously awaiting—a *hardy blue variety*? Treasured in my memory is the recollection of a garden near Cape Town, where the whole surface of a large piece of water is covered with the beautiful *N. stellata*

—a perfect sheet of blue, rendered even more intense by the African sky overhead. Truly a picture once seen, not easily forgotten. But it is time to recall my wandering thoughts. The purple shadows are lengthening as the sun sinks to rest behind the mountains, illuminating their eternal snows with a last gleam of tenderest rose colour. Another day has run its course, and ere long the dream which I have been dreaming will once again give place to reality. Nature will reawaken from her long winter sleep, and the flowers whose memory we have cherished will raise their heads to bid us welcome from a far-distant land.

BLANCHE GORDON-LENOX.  
Wolhurst, Colorado.

#### THE HONEYSUCKLES.

THE Honeysuckles met with in gardens may be readily divided into two distinct groups by their habit of growth and manner of flowering. The difference in habit lies in one section being of a climbing nature, requiring the aid of something wherewith to support the branches, and the other being of a dense bushy habit. The climbing ones, the majority of which have at one time or another been known under the generic name of *Caprifolium*, are well represented by the two British species *L. Caprifolium* and *L. Periclymenum*, which during the summer months are two of the

flowering *L. fragrantissima*, and *L. tatarica*. Of the two groups the climbing one provides by far the greater number of really ornamental species, and nearly every one is worth cultivating in gardens. Although not very fastidious with regard to soil, Honeysuckles thrive best in that of a rich loamy character, and when planting it is advisable to make certain that the soil is good and has been well cultivated. The positions best suited to these shrubs require a little consideration, for although they may be worth growing, all are not suitable for the same purpose. The accompanying illustration gives a good idea of the value of the stronger growers for covering arches, and they are equally useful for covering arbours, smothering unsightly fences, growing in tumbled and tangled masses over large bushes, or for clothing in a picturesque manner groups of rough, gnarled branches of Oak, Elm, Holly, &c. For this purpose the two British species are excellent in almost any part of the country, while in the south-west counties or other favoured spots *L. etrusca* and *L. sempervirens* can also be used. For other uses, such as the covering of short pillars or posts, the stiffer and shorter growing species, such as *L. glauca* and *L. Sullivantii*, are very useful, while for rambling over a low fence or rough tree root the pretty little variegated variety of *L. japonica* has few equals. Planting Honeysuckles requires care, particularly

the section under notice. Adult plants of several species transplant badly, and it is advisable to obtain young plants in the first place rather than try to transplant specimens which have reached maturity.

Of the numerous cultivated species and varieties of Honeysuckles the following form a selection of the best:—

*L. Caprifolium*.—According to Bentham and Hooker this is distributed throughout Mid and South Europe and West Asia, and is only naturalised in Britain, Cambridge and Oxford being given as the places where it is found. In many respects it resembles the common Woodbine. The flowers are borne in whorls from the apices of the branches and from the axils of a few of the upper

ARCH COVERED WITH HONEYSUCKLE IN AN OXFORDSHIRE GARDEN.

prettiest and most fragrant of our hedgerow plants, the latter being found almost throughout this country, while the former is met with in a few counties only. In this section the flowers are usually borne in whorls from the extremities of the branches, while those species of a bushy habit usually have their flowers in the axils of the leaves singly or two or three—rarely many—together. The name *Xystosteum* has been given to many of this set, and in some catalogues it is still erroneously kept up. Examples of the group are the British *L. Xystosteum*, the popular winter-

leaves. They are yellow or reddish yellow in colour, fragrant, and are succeeded by orange-coloured berries. In good soil it grows from 15 feet to 20 feet in height. The flowers are at their best from May to July. The common name of this species is Goat's leaf or perfoliate-leaved Woodbine. A variety called major, with larger leaves and flowers, is in cultivation.

*L. etrusca*.—Although it is doubtful whether this South European species will prove satisfactory in the colder parts of the country, for the more favoured localities it is excellen-

Making shoots quite 30 feet long it is valuable for covering high arches and pergolas. The stems have a purplish tinge and are clothed with large oblong, hairy leaves, main and side branches alike being terminated with immense inflorescences of deliciously scented yellow flowers, which with age vary in shade from pale to deep yellow. At Kew it is cultivated out of doors, but a much finer specimen is to be seen in the Himalayan house, the little protection thus afforded being fully appreciated by the plant. In nurseries it is often known as *L. gigantea*; the "Kew Hand List," however, gives *gigantea* as a synonym of *L. etrusca*. A variety known as *superba* is in cultivation.

*L. flava*.—This is a North American species found in South Carolina and in the Catskill Mountains, New York, whence it was introduced in 1810. It has twining stems but it reaches no great height, being suited more for a short pillar or stake than a high building. The flowers are large, rich orange-coloured, and fragrant. They are borne in June and July. It is more suited for southern than for northern counties.

*L. glauca*.—Like the last named this is a North American species suitable for a short pillar. Its chief beauty lies in the deep yellow flowers and glaucous leaves.

*L. hirsuta*.—Like the majority of Honeysuckles this has been known by a variety of names, *L. pubescens*, the name under which Loudon described it, being one of the most common. It was introduced from North America in 1822. The leaves are broadly ovate and very hairy. The flowers are borne freely in June and July and are yellow. It grows 12 feet or 14 feet high.

*L. japonica*.—A very distinct Honeysuckle from China and Japan, and very suitable for quickly covering a low fence, group of rough poles, or other support. In good soil it is a rapid grower, making a dense tangled mass of thin wiry stems clothed with evergreen, ovate leaves 2 inches to 3 inches long. The flowers

are borne usually in pairs from the axils of the leaves and are deliciously fragrant; the colour is pale yellow. Of the several varieties in cultivation *L. j. var. flexuosa*, with dark green leaves and reddish stems and flowers; *L. j. var. halliana*, which is very like the type, but which continues flowering until well on into the winter; and the pretty golden variegated-leaved *L. j. var. aureo-reticulata*, commonly called *L. brachypoda* var. *variegata*, are the most distinct.

*L. Perilymenum*.—This is possibly the best known of all the Honeysuckles, for during summer its presence in the hedgerows adds beauty and fragrance to many a roadside all over the country. For covering a summer-house no better shrub can be found, for it combines beauty and fragrance with a good and picturesque appearance. It grows from 15 feet to 30 feet high, and is distinguished from *L. Caprifolium* by its greener and unjoined leaves. The flowers vary in colour, usually being reddish or buff coloured. Several varieties are in cultivation, of which the Dutch Honeysuckle *L. P. var. belgica*, a very free flowering, reddish coloured variety; *L. P. var. quercifolia*, a form with leaves resembling in shape those of the common Oak; and *L. P. var. serotina*, which flowers later than most of the others, are most frequently met with.

*L. sempervirens*.—It is only in the most favoured parts of the country that this—possibly the most lovely of the exotic species—can be cultivated out of doors with success, for although it lives outside at Kew it cannot be compared with plants grown under glass. Occasionally it is met with on walls doing well, and a year or two ago a good plant was growing and flowering freely on the south wall of a cottage as far north as Cheshire. It was introduced from North America in 1656, grows to a height of 15 feet or 20 feet, and bears ovate, glabrous leaves, and good-sized inflorescences of tubular flowers, which are scarlet outside and yellow within.

*L. Sullivantii*.—Like *L. flava* this is a North American species, suitable for clothing a short pillar. It is remarkable for its clusters of bright red fruits.

W. DALLIMORE.

## THE FERN GARDEN.

### IDEAL FERN HABITATS.

In the plant world, as in that of humanity, it is the exception rather than the rule for the individual to be naturally placed under such favourable conditions of environment that its potentialities can be developed to the utmost. As a rule the all but inevitable struggle for existence necessitates some sort of compromise, which may mean such a degree of handicapping that the real merits and capabilities are hardly at all developed. Hence in the Fern world we frequently find that, although Ferns as a rule are constituted to flourish in shady, damp, and sheltered situations, and although by virtue of their robust and hardy nature they manage to exist in places where these essential needs are but very poorly provided, the result is that they present stunted, unattractive growth with but a trace of the natural charm which more favourable conditions would enable them to develop. Nature, with her usual knack of adapting her creations to the most varied conditions, has, in the course of aeons of time, endowed many of the original shade and moisture-loving Ferns with the capacity to withstand both drought and sunshine, as we may see evidenced in such genera as the Cheilanthes, Nothochlaena, and even in our familiar Ceterach officinarum. In all these cases, however, we find the adaptation to detract from the foliose, pendulous grace of the major portion of the Fern tribe, the fronds of necessity become more or less hard and leathery, and thus, though undoubtedly pretty when at their best, cannot for a moment compare with the stately grace of the Tree and other Ferns which fill our antipodean valleys or even with the smaller but yet delightful frondage of our largest native Ferns, such as the Lady, Male, and Shield Ferns, which deck the sheltered combes of our humid western counties.

The aim of gardeners is to obviate, as far as possible, the natural handicapping to which we have alluded, and to provide the plants taken in hand with as nearly as possible ideal conditions of growth, and supplied with all incentives to perfect development. To do this effectively we have, however, in the first place to study Nature to ascertain under which natural conditions the plants are at their best, and, having acquired this knowledge, to apply it as far as practicable to cultivation. Thus to see our native Ferns at their best we must visit one of our deep western valleys, where a rushing, tumbling stream brawls between high, rocky banks hemmed in by trees, the two latter sheltering admirably from boisterous breeze and broiling sun. The very air is humid from the proximity of the stream, and the leafy, rocky soil is never dry. Here are all the essential conditions of Fern life at their best, and we see the results all around us in waving masses of feathery frondage, while a closer inspection will show the ground beneath to be covered with flourishing colonies of Blechnums, Oak Fern, Beech

THE ROYAL FERN (*OSMUNDA REGALIS*) BY WATERSIDE.

Fern, *Polypodium vulgare*, and others of the smaller Ferns. Leaving the glen and reaching an adjacent road we may still find all these, but in a much smaller state, and in many cases stunted and torn by the wind, and thus void of all the charm of their more favoured neighbours. Presently, however, the road dips into a hollow and becomes a shady cutting, walled in on either side by rough, retaining stone dykes, while overhead the trees almost meet, and thus once again we have a Fern paradise, but with a difference. Nature, as we have said, has varied her creations to such varied conditions. Here we have more air and light, and the loose stone dykes afford a combination of perfect drainage with constant dampness, that better suits the tastes of other species of Ferns, which, moreover, under the freer conditions of growth in the dell we have left, would be overgrown and enfeebled.

Hence in these walls we find colonies of the various Spleenworts, associated with Polypodies, common, Oak, and Beech Fern, and last, but not least, the beautiful, strap-fronded Hart's-tongue will be found, not merely in a comparatively small state in the chinks and crevices, but also in robust condition along the foot. Such dykes, indeed, form ideal hunting grounds for the Fern enthusiast, for besides the wall or rock Ferns proper there are sure to be innumerable seedlings of the dell species, which, being precluded by their position from becoming huge, full-grown specimens, make up for this by their numbers, and in this way increase the hunter's chances of a find. In such a lane or cutting we have frequently found no less than fifteen or sixteen different species, and it is clear, therefore, that a sunken artificial rockery shaded judiciously by trees may represent one of the ideal habitats we have in view. Some Ferns, however, are more exacting in their water requirements than even the dell Ferns aforesaid, unless, indeed, that dell develops here and there—as it well may do—into a local bog or marsh. In that case we may find a colony of the Royal Fern (*Osmunda regalis*) lifting its tall, fertile fronds from amidst an abundant circle of more drooping barren ones; a grand sight indeed under ideal conditions. On the banks of the Upper Dart we have seen this splendid Fern with huge fronds 10 feet high covering the stream-banks like a coppice. The secret of such growth is that although the crown of the Fern is well above the water-level, its deeply penetrating roots are really below it, and, given these conditions, the Osmunda, owing to the toughness of its fronds, will stand considerable sunlight without damage. Naturally, this fact renders it particularly adapted for water-side culture generally, in proof of which we need only refer to our illustration of a beautiful specimen, the condition of which attests how perfectly its particular needs have been met and how entirely the ideal has been realised.

CHAS. T. DRUERY, F.L.S., V.M.H.

## GARDENING OF THE WEEK.

### KITCHEN GARDEN.

#### THE HERB BORDER.

**B**Y no means the least important part of the kitchen garden, this should now receive careful attention so that a constant supply is assured. All the perennial kinds should be surface dressed. Mint should have all the old growths cut clean to the ground, using a pair of shears for the purpose, and the surface dressed to the depth of 2 inches either with well-decayed leaf-soil, or, better still, old hot-bed material passed through a coarse sieve. At the same time lift sufficient roots, box up, and place in cold frames or cool orchard houses for supplying green growths early in the year.

Lemon Thyme thrives best in a light gritty compost, the sweepings from the roads answering well. Keep the plants well supplied with this and they will last in a healthy vigorous condition for years. Common Thyme should be dressed over

with old hot-bed material, and Chives receive a dressing annually of well-decayed farmyard manure.

#### PARSLEY

which was sown late in the season and has not been lifted and planted in frames, if likely to be required during the winter, should have some protection. Either place old lights over it, or failing this erect a light wooden framework and cover with mats in severe weather. That which is growing in frames if planted as advised will now be well established, and the lights should be kept off whenever the weather will permit, making use of the light for covering only during snow and severe frosts, for the hardier it is grown the better will it be.

#### CAULIFLOWERS,

being wintered in frames, owing to the mild autumn, are in a very forward condition, and every endeavour should be made to keep the plants as stocky and hardy as possible or they will become much drawn before the spring and suffer in consequence. If by any chance this crop has failed, sow now in boxes Walcheren, Magnum, or Early Forcing. Raise the plants under glass in a cool house, prick out into other boxes as soon as ready, and if grown on gently through the winter, though a little more trouble, they will be little behind the sowings made in September.

#### RHUBARB.

Lift and place in heat good quantities of the early kinds, or it may be forced along by placing tubs or suitable pots over the crowns where they are growing, but sufficient material must be placed over them to create a gentle heat. One part long stable litter to three parts Oak or Beech leaves is best for the purpose.

#### SEAKALE

should now be introduced in large quantities to the Mushroom house to keep a regular supply, or brought on under pots in the open in a similar way to Rhubarb.

#### TOMATO PLANTS

which are intended to fruit all through the winter will now require a good deal of attention. The flowers should be fertilised as they open daily, and the temperature increased, but admit air on every favourable occasion. Do not over water the plants and keep the houses as dry as possible, or in all probability the foliage will be attacked by fungus.

E. BECKETT.  
*Aldenham House Gardens, Elstree, Herts.*

### THE FRUIT GARDEN.

#### PINE-APPLES.

In cultivating the Pine-apple, its winter treatment, owing to the short sunless days, demands perhaps closer attention than that of any other season. No attempt at that time should be made to hasten the growth of the plants, as it would weaken them to a degree that would lead to disappointment. All the light possible should be afforded by washing the glass of the structures, and during spells of severe weather, in order to prevent the necessity of using an excessive amount of fire-heat to keep up the desired degree of temperature, the houses should be covered at night with a suitable protector. Fruiting plants of Smooth-leaved Cayenne, Charlotte Rothschild, and other good winter fruiting varieties should have a night temperature of from 65° to 70°, with a day rise of 10° and a steady bottom heat of about 80°, while a moderately humid atmosphere should be upheld by damping the floors and surface of the beds in order to promote free swelling of the fruits. Examine the plants weekly, and give enough tepid water, to which a little Peruvian guano or other suitable fertiliser is added, to keep the soil moist throughout. Excessive moisture, however, either at the roots or atmospherically, will cause an undue growth of the crowns, and thus blemish the symmetrical appearance of the fruit. Remove suckers not required for propagation, and discontinue watering each plant when its fruit commences to colour. The Smooth Cayenne after being cut from its plant will keep

in good condition for some considerable time if placed in a dry cool room.

#### SUCCESSIONAL PLANTS.

Queens intended for starting early next January to afford ripe fruit in June should be now strong sturdy plants, and they should for the present have their growth arrested by the maintenance of comparatively low temperatures, viz., that for the night ranging in accordance with the condition of the weather, from 55° to 60°, with a slight day rise, air being admitted, when by the aid of solar warmth it reaches 65°. A bottom heat of from 75° to 80° should be aimed at, but in order to secure this it may be at times necessary to readjust the valves, owing to forcing the fires to keep up the required atmospheric temperature in severe weather. A moderately dry atmosphere compatible with the low state of the temperature must be preserved, though it will be necessary when the fires have to be pushed, to guard—by damping the floors, &c.—against its becoming injuriously dry. During the resting period careful judgment is needed in watering the plants, for serious injury accrues from either too much or too little being given.

Young plants of the Queen variety raised from suckers potted in August or early September are now well rooted, and should be subjected to similar treatment as recommended above for successional plants. Those of Smooth-leaved Cayenne, however, especially if they were late in being potted, should be afforded sufficient warmth and moisture to keep them gently growing; for this about 5° more than advised for successional plants of Queens will answer well.

T. COOMBER.

*The Hendre Gardens, Monmouth.*

### INDOOR GARDEN.

#### GARDENIAS.

The earliest plants that have had a season of comparative rest in an intermediate temperature and have made strong and well-matured growths may now be placed in the warmest part of the stove. Liberal feeding should be practised. Later batches that have completed their growth may be placed in a lower temperature, which will hasten ripening of the growth. Feeding must in their case be discontinued and less water given them until placed in heat again. It is not advisable to keep them in a cooler temperature too long or the flower-buds may drop. A sharp look out must be kept for insect pests and measures taken to eradicate them.

#### POINSETTIAS

that are beginning to show their bracts should be fully exposed to all possible light, and feeding should be discontinued. The later plants should be liberally fed and afforded a warm temperature in order to encourage strong, healthy, and well-matured growths, which are essential to the forming and finishing of fine bracts.

#### BOUVARDIAS.

When the pots are well filled with healthy roots frequent doses of weak liquid manure will be beneficial, and presuming the plants to be backward in flowering, which they are in most districts this season, they should be placed in a temperature of about 55° or 60°, where the blooms will soon open. Green fly is sometimes troublesome. Fumigation is a certain cure, but it is best used as a preventive. Red spider is liable to attack these plants, but this a sign of insufficient moisture at the roots more often than in the atmosphere.

#### CYCLAMENS.

For a succession of these plants another sowing should be made now, as advised in former calendar notes. Keep the seedlings near the glass and never allow them to suffer from want of water. Vaporise as a preventive rather than a remedy against aphids. The earliest of last year's seedlings are now in the height of their beauty, and as the pots are full of roots the plants will take almost unlimited supplies of water. When the flowers are taken from the bulb they should be

done by a smart pull; when cut the stems bleed and exhaust the plant.

## BULBS

that are plunged in ashes should be examined occasionally, and when the tops begin to grow they should be removed into a frame and the light subdued until the natural colour is gained. Let them progress slowly until the time arrives for forcing. It is easy from now onwards to secure a continuous supply of flowering plants by forcing successive batches until the final lot will flower naturally without any artificial assistance. Cool, slow treatment of most bulbs produces the finest display, and the flowers last for a longer time in perfection.

JOHN FLEMING.

Wexham Park Gardens, Slough.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

## GRAPES FOR EXHIBITION.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I am indebted to your correspondent, a "Grape Grower from Scotland," for the courteous way in which he places before your readers his reasons for differing from me in his estimate of the Black Alicante Grape. At the same time, I must say I am somewhat puzzled by the questions he puts to me. The point of disagreement is seemingly that in giving my estimate of this Grape I stated that it was a variety of easy culture. What does your correspondent say of it himself? He says: "Now we hear this remark so often, and we know that in the opinion of most judges this variety is considered so easy to grow, that it ought not to count so high as most others that may be placed against it in competition." This weighty evidence adduced by "Grape Grower's" own pen, in confirmation of my estimate of the Grape as to its being of easy culture, exempts me from saying more on this point, and I can only reiterate what I have said before, that this is one of the easiest of all Grapes to grow, one that crops heavily, and puts on a dense and beautiful bloom in a short time; the Vine has a sturdy and strong constitution, and, as an amateur's black Grape, either for exhibition or for dessert in winter, it is of all others, in my opinion, the best. As regards its adaptability and value as a market Grape, I will call Mr. Peter Kay as witness. This is what he says of the Alicante in a paper read before the members of the Horticultural Club some time ago: "My own experience is that taking houses of equal size, one planted with Alicante, one with Colman, one with Muscat of Alexandria, and one with Cannon Hall, and taking, say, five years' result of sales, Alicante would come out the best, Gros Colman next, then Muscat of Alexandria, and last Cannon Hall." It is interesting, and also I must say surprising, to hear that such accomplished Grape growers as Mr. Lunt and Mr. Kirk find a difficulty in growing this variety, and your correspondent unconsciously, no doubt, is rather hard on me in asking me to give the reason why. It would be interesting to hear from these gentlemen as to their experience in the culture of this Grape.

OWEN THOMAS.

## CACTUS DAHLIAS FOR THE GARDEN.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In THE GARDEN for the 18th ult. I gave a list of the finest Cactus Dahlias, basing my choice mainly on their merits as exhibition varieties, though at the same time not forgetting their value in other respects; but now, on noticing Mr. S. W. Fitzherbert's note asking for those sorts which are most suited to the decoration of the garden, I give the names and colours of some twenty for that purpose. First, however, before going into this, I would point out one or two facts which seem to be lost sight of by many amateurs, who I am afraid expect too much of the Cactus

Dahlia, or, in other words, expect it to grow, thrive, and produce an abundance of first-rate flowers without the least attention whatever. How often do we see Dahlias planted in shrubberies where there is not enough nutriment to support a weed, or planted in borders which are filled with perennials and so cannot have the soil properly prepared for them; then, when failure results, the Cactus Dahlia is condemned as useless except when pampered and coddled to get it to perfection for an exhibition. We have heard the old tale of bad habit, hidden bloom, and general failure so long that it begins to get stale. Many varieties of Cactus Dahlias are grand when properly grown, but once and for all let me say that the Cactus Dahlia will not grow in situations unfit for anything else. It must have culture, and good culture, too. We have bushes of Cactus Dahlias even now (late October) which are a complete mass of bud and flower. Several varieties are included which I mentioned on the 18th ult., these fortunate flowers possessing exhibition qualities and being also useful for decoration and cut bloom. The following are the best:—

*Mrs. Edward Mawley*.—Yellow.*Mrs. Winstanley*.—Orange-scarlet.*Mrs. J. J. Crowe*.—Yellow.*Uncle Tom and Aunt Chloe*.—Dark maroon.*Gabriel and Richard Dean*.—Red, tipped white.*Alpha*.—White ground, speckled crimson.*Britannia*.—A most useful Dahlia.*Florence*.—Yellowish orange.

*Floradora*.—Mentioned last week, but not described. A flower which produces an enormous quantity of bloom, the petals being claw-shaped. The colour is purplish crimson.

*General French*.—A bushy-growing, wiry-stemmed variety, producing medium-sized flowers of a terra-cotta colour.

*Mrs. McKergow*.—Amber colour, dark foliage, free-flowering and upright in growth.

*Major Hobbs*.—Clear rose, too heavy for exhibition, but a good deep flower of a beautiful colour.

*Roznhagen*.—Rosy lilac, black wiry stems, small flowers freely produced; a variety raised in Holland, and useful as a garden plant.

*Wm. Jowett*.—Brilliant scarlet, tall grower, exceptionally long stem, and a late autumn-flowering variety.

*Capstan*.—An older variety, dwarf, and producing a number of blooms of a soft brick-red colour.

*Countess of Lonsdale*.—An old variety, but a favourite for cut bloom and decoration.

*Magnificent*.—Still one of the best for all purposes, and especially good as a garden variety, its blooms seldom coming shallow when undibbed.

A good number of older flowers might be mentioned if I trespass upon the decorative section proper, but that I do not wish to do. Apart from these the following eight are all good:—*Stella*, *Princess Ena*, *Mrs. John Goddard*, *Beatrice*, *Alfred Vasey*, *Captain Dreyfus*, *Pretoria*, and *Mars*. Even now we have not mentioned a white, but for this we would recommend *Miss Webster*, *Lord Roberts*, or *The Queen*.

DAHLIA.

## DRESSED CARNATIONS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—It was with interest that I read the remarks on the subject of dressed Carnations in a recent issue. Why, indeed, should Carnation blooms have to be subjected to such mutilation as entirely to lose their natural beauty and form before they are considered fit to compete for prizes at our Carnation shows? If flowers are defective in any way they should be left at home; if they have no defect bring them to a show; but do not let us have them served up on paper plates with nothing but the petals showing, and not even all of these.

What do people go to shows for? I think for two purposes, firstly, to see beautiful plants well grown; and, secondly, to make notes of what they would like to grow themselves. Now imagine anyone going to an exhibition of dressed Carnations with the second object in view, not to mention the first.

They see Carnations, or rather a certain percentage of the petals of Carnations, and they take down the names of those they fancy; they are not allowed to see the calyx, much less the stalk; they send an order for plants perhaps, and in due course receive them. They plant them with great care in the garden only to find that the majority die. Now, this is not a state of things that is at all as it should be, and I feel sure your readers and everyone, except, perhaps, the professional "dresser," will gladly welcome the change which I hope is coming when we shall see these lovely flowers, exhibited in vases or bowls, cut with long stalks, I do not mean each bloom cut separately, but the whole stem with flowers and buds on it, arranged with their own grass in such a way that one can see at a glance what the bloom is, how it grows, and in fact the general habit of the plant which produced it.

How much better this and more interesting than the ridiculous pastry-cook fashion of dishing them up. And let us have more of the hardy border varieties, for I think these are what most people want. I grow all mine entirely in the open, and they do well and have given a profusion of bloom this season through July, August, and September, and even to-day (October 27) there are blooms on many of the plants. This I have only done by discarding numbers of varieties and keeping only those which are hardy, and raising plants from seed, from the best of which I keep the layers, and I find these make stronger plants generally than those which have been reproduced from layers for a greater number of years. As to which are the best varieties to grow I think this depends greatly on the locality and soil. Procure if you can plants that have been proved to succeed in soil similar to your own, and get them from a colder rather than a warmer district.

Bronwydfa, St. Asaph.

W. A. WATTS.

## CUTTING DOWN HARDY PLANTS.

[TO THE EDITOR OF "THE GARDEN."]

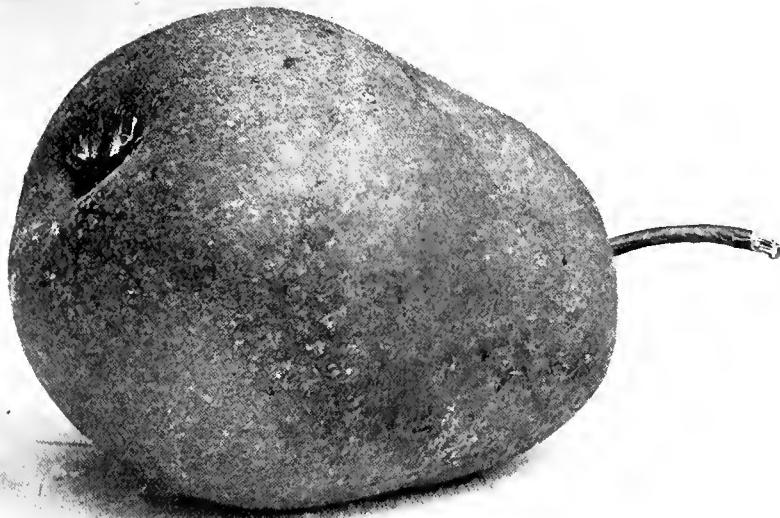

SIR,—I was glad to find Mr. Crook (page 162) calling attention to the barbarous practice of cutting down many of our hardy plants immediately the flowering is over. Nothing can be more detrimental to any plant than to deprive it of its foliage just at the time it is most required. How is it possible for the roots to perform their proper functions if we deprive them of their leaves and stems? I have often been grieved to see large plants of Delphiniums, Peonies, Pyrethrums, and sometimes the Lily, cut down close to the ground directly flowering is over, and after this operation has been performed for a few years the owners of the plants wonder why these look sickly and cease to throw up strong flower-spikes. The wonder to me is how they manage to live at all after such rough treatment. No amount of help in the way of manure water or any other stimulant will compensate for this annual cutting down. Where space cannot be devoted to these large growing subjects it would be far better to grow plants of less robust habit than annually to cut down after flowering some of the finest and most showy of our herbaceous plants. A little forethought at the time of planting, with a little judicious arrangement, would often obviate the necessity of the practice. Mr. Crook makes some capital suggestions how to get over the difficulties, and I see nothing objectionable in the foliage of these plants. On the other hand, I see much to admire in them, for their varied tints often make a good contrast and help materially to brighten up the herbaceous border.

T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

## [TO THE EDITOR OF "THE GARDEN."]

SIR,—I note that Mr. Crook is anxious for more opinions on the above subject. The question appears to me to be simplicity itself, and not to admit of two opinions. I cannot imagine anyone conversant with horticulture denying that cutting down sappy stems to the ground-level must weaken a plant. Some vigorous subjects, when grown under the best cultural conditions, bear the check entailed without appearing to suffer, just as a strong man can stand a little blood-letting without feeling the

PEAR MARECHAL DE LA COUR. (*Two-thirds natural size.*)

worse for it, but both are weakening operations. It has been found that Delphiniums are sufficiently robust to endure this cutting down without material detriment, and it is with this knowledge that Messrs. Kelway give the advice quoted by Mr. Arthur Goodwin (page 203). Certainly the finest autumnal display is produced by this method. In a garden that I know the great rows of Delphiniums are cut to the ground-level immediately the flowers fade, and blossoms again grandly in the autumn, but it is only sturdy subjects such as these that fail to show signs of the drain of strength that results from removing the whole of the flower-stems and thus depriving the plant of the sap that would naturally return to it. In plants of less vigorous habit this system, as is shown by Mr. Crook's examples, is followed by palpable loss of strength manifested in a failure to flower the succeeding year. In weakly-growing plants the removal of the whole of the sappy flower-stems might easily prove fatal. Doubtless the best method to conserve the strength of any plant is merely to cut the flower-heads off, and thus prevent it exhausting itself by perfecting seed. Anything in excess of this must mean weakening it more or less, very possibly infinitesimally so, but the loss of every drop of sap means a proportionate loss of strength.

S. W. FITZHERBERT.

#### NEGLECT OF BRITISH FERNS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—With regard to the note on the above subject (page 281), it is, I should say, most probable that we shall have to wait till fashion takes another turn before the many beautiful hardy Ferns will take the position in gardens that they held about thirty years ago. To a certain extent the tender Ferns can also be included in the same category, for though prizes are offered for them, and a few kinds are grown in immense numbers for decoration, the general collections are not maintained to the same extent they once were, not only in private gardens but also in nurseries; in the last named such would not be the case if there was a paying demand for them. Fashions in plants seem to move more or less in cycles, as will be noted by those who remember the many beautiful shrubs introduced from Japan by Robert Fortune and J. G. Veitch, and the prominent position for a time held by flowering shrubs in general, then their period of comparative neglect, while now they have attained a popularity never before equalled. Zonal Pelar-

goniums, too, are again in fashion after being long under a cloud, but conifers are not planted nearly so largely as they were forty years ago. The show and tricolor Pelargoniums of the sixties are now rarely seen, and the different stove foliage plants lacking the stimulus given to their culture by the numerous introductions of thirty-five years ago from the South Sea Islands are, apart from a few subjects, not nearly as popular as they once were. On the other hand, hardy plants in general, Chrysanthemums, and Begonias are now grown more than ever.

H. P.

## THE FRUIT GARDEN.

### HARDY FRUITS IN SEASON.

#### PEAR MARECHAL DE LA COUR.

**E**QUALLY well known is this Pear under the name of Conseiller de la Cour, it has been grown in this country for at least half a century. I do not think its merits have ever been fully recognised by fruit growers. In the southern counties I consider this variety one of our best early November Pears, and though, of course, it cannot compete with Doyenné du Comice as regards flavour, it is really excellent when given good culture. Many fruit lovers like the peculiar sub-acid flavour of this Pear. The fruits are very handsome when gathered from wall trees, but I find our best flavoured fruits are those grown on pyramid trees in a well-drained soil. The late Mr. R. D. Blackmore thought this one of the finest Pears in cultivation. For heavy land I do not recommend it; the tree is hardy and a good grower. On a chalk soil it does well as a standard if grown on the Quince stock, and is much valued as a market variety during early November.

G. WYTHES.

#### SINGLE CORDON FRUIT TREES.

NATURALLY it is to the interest of the market grower to produce Apples and Pears in quantity, and therefore he has only to concern himself with

a limited number of varieties which suit his purpose, but with amateurs and owners of private gardens the case is entirely different. Apart from the interest there is in growing a number of varieties, there is the fact that by planting suitable sorts a succession of good fruit is obtained over a long period, and, now that the planting season is here, I make no apology for singing praises of the single cordon system as an economical method of growing hardy fruit in private gardens, particularly small ones. It may not be necessary to describe a single cordon, but briefly it is a tree with one stem, and the object of the cultivator is to get that stem furnished from base to summit with fruit-spurs. This done, the amount of fruit that one tree will produce is considerable, and the examples obtained from cordon trees as a rule are unsurpassed.

#### SINGLE CORDONS FOR WALLS.

In the old days the great object was to furnish garden walls with espaliers, and, judging by the symmetrical appearance of many time-honoured specimens to be seen to-day, there is nothing new about the art of training fruit trees. But we move quickly in these times, and the furnishing of walls with horizontal espaliers was a slow process—too slow, indeed, for the demands of the present. Besides, an espalier takes up a good deal of room, and the man with one wall could only accommodate a single tree, and in consequence only grow one variety. But the introduction of the single cordon system has done away with all this. It is true far more trees are employed, but it is the quickest way of furnishing a wall and the most profitable, because from a batch of cordons many a crop of fruit may be obtained before an espalier has more than half covered the space. It is for comparatively low walls, however, that single cordons more particularly commend themselves. An espalier tree on a 10-feet or 12-feet wall when fully established is practically a permanent institution, but on a wall half that height its energies have to be checked just when it has reached a useful size. Above all others the single cordon tree appeals to the amateur with only a small garden. His walls are low, and generally the space is limited, but he has a commendable desire to grow a variety of Apples and Pears. How can he do it better than by employing single-stemmed trees that can be grown 18 inches apart, and may be placed in positions where a trained tree would be out of question for the want of room?

#### CORDONS IN THE OPEN.

But a wall or a fence is not absolutely essential for the successful culture of single cordon trees, and they may be readily grown in the open garden. "I cannot grow fruit trees in my small garden; there is not enough room," is a complaint frequently heard, and it is a reasonable one when we take into account the developing capacities of bush and pyramid trees. The single cordon steps into the breach, and the difficulty vanishes. All that is necessary by way of preparation is to fix two stout upright posts in the ground about 6 feet high, with one or two upright supports in between, and stretch four strands of wire from one to the other. The framework is then provided for the support of the trees, which should be planted at from 18 inches to 2 feet apart, and have the stems laid in parallel to each other at an angle of about 45°. It will be seen from this that a number of trees can be accommodated in a single row across a garden, though the latter be small, and a selection of varieties be represented for succession. For the purpose of planting it is advisable to take out a trench along the entire length about 18 inches wide and 12 inches deep. The subsoil should be broken up to the depth of another 12 inches, and then a portion of the surface soil be replaced along with the addition of mortar rubble, wood ashes, or road scrapings if the soil is retentive. This will reduce the depth to about 6 inches, at which the trees may be placed in position. Cover the roots carefully with soil,

tread this firmly, and place a mulch of well-decayed manure on the surface. In the selection of trees let me advise good specimens. They will cost a little more to begin with, but they are cheaper in the end. Three or four year old trees are the best, because their foundation has already been laid in the nursery.

#### CORDONS ON ARCHES.

Here again we have another purpose for which single cordon trees are well adapted. Over narrow garden walks, single arches placed at intervals are anything but unsightly. On the other hand, they are attractive objects, and, what is more to the point, useful if furnished with fruit trees. For the purpose in view a single arch of iron, upright at the sides and bent over the top, is required, and a tree may be planted on either side, the leaders being encouraged to extend till they meet, when they may be stopped and treated as spurs. I know several small gardens where cordons are grown in this way, and not only add to the general appearance of the garden but useful crops of fruit are obtained from them.

#### PRUNING CORDON TREES.

For the purpose of this article the operation of pruning can be summed up in a few words. In the first place the idea is to keep the tree to a single stem, hence the necessity for removing all side shoots. This can partly be done in the summer with advantage by going over the trees early in August and pinching back the growths to five or six leaves, completing the operation at the winter pruning by shortening the shoots to two buds. Mistakes are often made with single cordon trees through being in too great a hurry to get them to the top of the wall or fence by leaving the leading shoot of the current season's growth at its full length. The consequence of this is that the lower buds on the shoot are apt to remain dormant and not break the following year, and a length of bare spurless stem is the result. To avoid this the leading growth should be shortened back to about three parts its full length until the tree has reached the limit, after which it may be treated in the same way as the side shoots.

#### VARIETIES OF SUITABLE APPLES AND PEARS.

Nearly all the best varieties of Apples and Pears will succeed as cordons, but as a guide to intending planters I append a short selection of varieties arranged in order of ripening:—Apples (culinary): Duchess of Oldenburg, Lord Grosvenor, Ecklinville Seedling, Bismarck, Lord Derby, Warner's King, Cox's Pomona, Golden Noble, Peasgood's Nonsuch, Lane's Prince Albert, Newton Wonder, and Alfriston; dessert, Beauty of Bath, Devonshire Quarrenden, Worcester Pearmain, King of the Pippins, Ribston Pippin, Cox's Orange Pippin, Allington Pippin, Gascoigne's Scarlet, Hormead Pearmain, and Sturmer Pippin. Pears: Jargonelle, Marguerite Marillat, Williams' Bon Chrétien, Clapp's Favourite, Beurré Hardy, Emile d'Heyst, Louise Bonne of Jersey, Doyenné du Comice, Pitt-maston Duchess, Thompson's Winter Nelis, Glou Morceau, and Josephine de Malines. G. H. H.

## NURSERY GARDENS.

MESSRS. THOS. CRIPPS AND SON,  
TUNBRIDGE WELLS.

**F**OR the production of both fruit trees and ornamental trees and shrubs the county of Kent has a most enviable reputation amongst horticulturists, and it would have been disappointing in a Kentish nursery to find this reputation not maintained. In visiting Messrs. Cripps' Tunbridge Wells nurseries, however, we did not anticipate disappointment, for we still remembered the

THE RHODODENDRON WALK IN THE TUNBRIDGE WELLS NURSERIES.

meritorious displays of Japanese Maples, conifers, and various hardy shrubs which they annually exhibit at the great London plant shows.

Situated as the nurseries are on a hill, or rather on various hills, in the highest suburb of the town, they have the advantage of a great variety of aspects, and one can also depend upon the plants being hardy and making sturdy growth. As showing how good the soil is here, there are several trees that have reached a good age and are of remarkable dimensions; we might mention the Turkey Oak, Andromeda floribunda, the Golden Catalpa, *Alantus glandulosa*, Golden Tulip Tree, several Acer, &c. A good idea of the vigour with which Rhododendrons grow may be had from one of the accompanying illustrations, which shows one of the principal drives through the nurseries. This is bordered on either side by a variety of trees and shrubs, in which Rhododendrons predominate. One can well imagine how beautiful a sight these banks of Rhododendrons must present in the months of May and June when their flowers are in full beauty, and the neighbouring residents are fortunate in being able to wander at will through these nursery grounds in Rhododendron time. It would be useless to mention varieties, for the collection here is one of the most complete. Should the visitor to the Tunbridge Wells nurseries chance to be there during early autumn his attention undoubtedly would chiefly be centred on

#### THE JAPANESE MAPLES,

of which Messrs. Cripps have one of the finest collections in Europe. They are therefore well qualified to judge of their merits, and this is their opinion: "Japanese Maples form one of the most beautiful introductions to our ornamental deciduous trees and shrubs introduced of late years; having grown them in our nursery borders for several years unprotected and uninjured by frost, we are enabled to recommend them with every confidence in their being perfectly hardy. They are specially suitable and effective for borders and shrubberies; in pots for conservatory decoration they are invaluable." We know of no hardy shrub that in the autumn can equal the Japanese Maple for variety and brilliancy of leaf colouring. Some there are of such an intense crimson as almost to be black; others are scarlet, pink, bronze, and tints too numerous to mention, if not impossible to describe.

Of new varieties we remarked three particularly beautiful ones—*Acer palmatum linearilobum gracile Crippsii*, the dark purple leaves deeply cut; *A. p. atropurpureum turbidense*, with bold foliage of a rich dark colour; and *A. p. atrosanguineum Fieldii*, more brilliant than the variety *sanguineum*. Of the better-known ones that were strikingly attractive, by reason of their rich colouring, we noticed *A. japonicum*, *A. aureum*, *A. laciniatum*, *palmatum dissectum purpureum*, *p. palmatifidum*, *p. roseum marginatum*, *p. versicolor*, &c. We must not omit to mention the golden-leaved Maple, *Acer pictum aureum*, which is a most handsome shrub; it has received an award of merit from the Royal Horticultural Society. *Acer Negundo variegatum*, so well known as a valuable tree for the shrubbery, is largely represented in these nurseries. The Sycamore in numerous handsome varieties, and *A. tataricum Ginnala*, whose leaves are a most brilliant red in the autumn, are also worthy of special note. The collection of

#### ORNAMENTAL TREES AND SHRUBS

is very extensive. Among some of Messrs. Cripps' own introductions we might mention *Azara Crippsi*, the Golden Catalpa, *Phyllanthus Crippsi*, and *Ptelea trifoliata aurea*. Of other hardy trees and shrubs of great merit were remarked the ornamental flowering Cherries, the Dogwoods, Thorns, *Cytisus*, *Cydonia*, *Eleagnus*, *Hamamelis*, Hollies, Privets, Magnolias, *Osmannthus*, Oaks, including the evergreen, scarlet, golden, Turkey, and Cork Oaks, numerous Elms, &c. Interesting amongst the large number of conifers is

#### RETINOSPORA OBTUSA CRIPPSII,

one of the best golden conifers we have. In growth it exactly resembles *R. obtusa*, while the colour of the foliage is a good golden-yellow. This conifer is said not to burn even when fully exposed to the sun. It has been awarded no less than three first-class certificates. Of other conifers in Messrs. Cripps' collection we would mention as being specially meritorious *Cupressus lawsoniana Triomphe de Boskoop*, *C. l. Shawii*, *C. l. minima*, and *C. l. minima glauca*, two pygmy globular-shaped varieties: *Fitzroya patagonica*, *Picea concolor*, *P. nordmanniana*, *Retinosporas* in variety, weeping and golden Yews, the weeping *Wellingtonia*, and *Cedrus atlantica glauca*. Fruit trees, Roses in pots and in the open

ground, and forest trees are also extensively cultivated by Messrs. Cripps and Son. Stove and greenhouse climbers, notably *Clematis* *indivisa* and *lobata*, *Cobea scandens variegata*, *Lapageria alba*, *rosea*, and *rubra superba*, *Schubertia grandiflora* (which grows most luxuriantly), and greenhouse Rhododendrons are important items amongst plants under glass. The collection of stove, greenhouse, and

#### HARDY FERNS

is a noteworthy one, the latter being particularly interesting, for few nurserymen now pay attention to their culture.

#### THE CLEMATIS

may be said to be a speciality with Messrs. Cripps, for not only do they grow a large number of plants, but many of the best-known varieties were raised in the Tunbridge Wells nurseries, for instance, *Enchantress*, *Fairy Queen*, *Grand Duchess*, *Lady Caroline Neville*, *Lord Neville*, *Marie van Houtte*, and *Marie Lefebvre*, all flowers of the lanuginous type. Such are some of the most noteworthy features of a Kent nursery that has done credit to growers and county alike for the past sixty years.

#### MESSRS. R. AND G. CUTHBERT, SOUTHGATE, MIDDLESEX.

PASSING through this delightful part of the county of Middlesex a few days ago for the first time I was delighted with the aspect of the country. Extensive, beautiful, and sylvan parks are noticeable in all directions, with gigantic Elms and other forest trees in rich luxuriance. The Elms here remind one of the historical avenues of the great park and forest at Windsor; all were evidently planted about the same time, in the reign of King Charles II. This is not the only matter reminiscent of Royalty and forestry in this part of the county. The village of Southgate may not inappropriately be termed a Royal village, for we are told it was one of the gates (Southgate) of entrance into the Royal chase and forest of Enfield in days gone by. How long the village is likely to possess this arcadian character is uncertain, for the force of the increasing outward growth of the Metropolis has already engulfed in its embrace many similar villages in the neighbourhood. One can never speak or think of Southgate without the name of Thomas Baines recurring to one's mind, a name that will be famous for all time amongst gardeners as that of the greatest and most successful specimen plant grower of the Victorian era. It is opposite to one of the entrances to the estate where Baines served so long as gardener that the nurseries of Messrs. Cuthbert are situated. The same atmosphere of old-world dignity characteristic of the county pervades the nursery. This has been in the possession of the Cuthbert family for some generations, and what redounds much to the firm's credit is the fact that most of the employees and their families before them have shared the labours and fortunes of the firm for this long time. After hearing so much of late years of new systems and new glass houses, there are those amongst us who believe that anything old must be associated with that which is obsolete and useless, and that to be up-to-date the old must be sacrificed to the new. This is no doubt true to a certain extent, but there is no success more solid and enduring than that built on the foundation of the experience and example of past workers. This is the success stamped very clearly on all the work at Southgate nursery. I must confess that the magnet attracting me to the Southgate nurseries was the Azalea, a plant which Messrs. Cuthbert have made a great speciality of for many years, and especially of the Ghent and Mollis sections. The Azalea has obtained for them a world-wide reputation by reason of the magnificent groups they have exhibited at the Temple and other shows in London. Especially fine was the collection shown by them at the Temple show of the Royal Horticultural Society last year, and which, for well-grown plants, floriferousness, and lovely shades of colour has never certainly been surpassed, and, next to the Orchids and Roses, no collection of plants in

the exhibition was more admired. To give some idea of the immense trade in Azaleas in this country, it will suffice to mention that Messrs. Cuthbert alone import some 10,600 plants a year. Add to this the thousands—they grow in their home and branch nurseries, and some idea may be had of the popularity of this beautiful plant amongst the flower lovers of England. It is from selected imported plants that such specimens as those shown at the Temple show have been produced. The thousands grown at home are intended for forcing in pots and for planting on lawns and in shrubberies. Some of these were being potted up on the day of my visit, and better rooted, stronger plants, and, what is more important, a better set of flower-buds it would be difficult to find. The time at my disposal when I called was very brief, but it was long enough for me to notice the splendid collection of Camellia trees in robust health and studded over with thousands of flower-buds. All are growing in houses apparently as old as the nursery, and the age of the specimen trees approaches in some cases to that of the houses in which they are grown. One also could not fail to notice the representative and excellent collection of flowering and foliage plants under glass, the up-to-date methods of propagation, the immense quantities of bulbs, and the attention given to all the best and popular hardy trees, shrubs, and herbaceous plants. O. T.

*variegata* and *Isolépis* as a margin made a really interesting display. Silver Flora medal.

Messrs. William Ball and Sons, Chelsea, contributed a few select stove plants, *Aralia triloba*, *Aglaonema costatum*, a Maranta-like plant; *Nephthytis picturata*, very striking and beautiful; *Polypondium irioides ramo-crystatum*, *Lilium sulphureum*, *Aralia elegantissima*, *Dracena Victoria*, very fine; *Maranta picta*, very pleasing; and *Phyllotectum Lindeni*, a green, almost sagittate-leaved plant, with white rib and veins.

Messrs. James Veitch and Sons, Limited, Chelsea, had a magnificent table of their Begonia hybrids, some of which were remarkable, e.g., *B. incomparabilis*, *B. Freebillyi*, *B. polypetala*, *B. Mrs. Heal*, of which some ten or twelve dozen were set up, making a dazzling bank of colour; the ever-flowering and compact *B. Idealia*, a most beautiful addition; *B. Julius*, a charming pink flower, and very free; the inimitable *B. Agatha*, which may at once be said to be a great improvement upon *B. Gloire de Lorraine*, the colour much the same, but with larger flowers and a better habit. *B. Success* is the darkest of these wonderful hybrids so far and somewhat later in opening. For brightness, brilliant effect, and large handsome flowers freely borne, Mrs. Heal is the gem of the whole collection so far; indeed, a wonderful addition to winter flowers. Silver-gilt Banksian medal.

Messrs. J. Waterer and Sons, Limited, Bagshot, staged a fine lot of conifers and allied things, notably such *Reticularias* as *R. leptoclada* and *R. plumosa aurea*, perfect examples in their way and well grown. *Abies hookeriana*, *Juniperus japonica aurea*, *Taxus Standishii*, *Cupressus lawsoniana lutea* the variegated Savin, *Sciadopitys verticillata* (the Umbrella Pine), *Abies concolor*, obviously a good plant for isolation or grouping, and several good Hollies, notably *Hix balearica*, and the yellow berried Holly being among these and in well-fruited examples. The collection was extremely fresh looking and attractive. Silver Banksian medal.

Messrs. Barr and Sons, Covent Garden, set up a few hardy flowers and other things, as early *Chrysanthemums*, *Kniphofias*, *Crocuses*, &c.; also some late *Michaelmas Daisies*. Among these latter, *Aster Amellus Framfieldi* was good, and the white flowered *Aster Tradescanti*, pretty in its characteristic garb; *Aster grandiflorus*, too, is open. Late struck *Chrysanthemums* were also shown in pots, and many autumn *Crocuses* and *Colchicums* were shown in pans and pots. Fruiting examples of *Phytolacca decandra* were noted, and flowers of the white *Scabiosa*. An early-flowering Roman *Hyacinth* was also shown, together with others of the ordinary kind, which are much later in flowering.

Mr. Robert Foster, Nunhead Cemetery, had a fine circular group of *Chrysanthemums* in excellent condition and much variety. The kinds were not named, but evidently contained not a few of the choicer kinds of recent date, as well as some good older kinds, and with Pompous and incurved flowers made a display of a highly creditable character. A margin of *Fenis* was formed about the base. Silver Banksian medal.

Mr. C. B. Gabriel, Horsell, Woking, contributed a magnificent lot of zonal *Pelargoniums* respondent in their many brilliant colours. The following were some of the kinds shown: *Herrick* (crimson-scarlet), *Mary Pelton* (pink, very large), *Cerise* (scarlet), *Mary Beeton* (white), *Lady Laurier* (orange-salmon), *Lilian Duff* (crimson), *Lord Kitchener* (scarlet), *The Mikado* (rose-scarlet), *The Sirdar* (magnificent crimson), *Winston Churchill* (a curious rose-purple, with white centre), &c. The exhibit as the production of an

#### SOCIETIES.

##### ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE—NOVEMBER 4.

PRESENT: Mr. W. Marshall (chairman), and Messrs. C. T. Dryer, H. B. May, Jas. Walker, C. W. Knowles, J. F. McLeod, N. F. Barnes, John Jennings, Jas. Hudson, Chas. Dixon, Chas. Jeffries, C. J. Salter, H. J. Cuthbert, Chas. E. Pearson, C. E. Shea, W. P. Timson, E. H. Jenkins, W. J. James, and the Rev. F. Page Roberts.

MR. H. B. May contributed in his usual tasteful style Tree Carnations with Ferns interspersed. Of the former we noted fine showy groups of *Triumphans* and *Resplendent*, both excellent, free-flowering, and scarlet in colour. Dwarfness and compact habit were also noticeable. Prince of Wales is an excellent crimson with lighter shade, good in form, free, clove-scented, and obviously of vigorous habit and constitution. Snowdrift (white) and Etna (scarlet) were also shown. Noticeable among the Ferns were *Adiantum farleyense* and *Davallia mooreana*, and with *Ficus radicans*

JAPANESE MAPLES IN MESSRS. CRIPPS' TUNBRIDGE WELLS NURSERIES.

amateur was creditable in the extreme; indeed, many of the kinds could hardly be surpassed by the best professional growers of to-day. Silver Flora medal.

Messrs. J. Peed and Son, West Norwood, had a group of Begonias Mrs. Leo de Rothschild, the plants freely flowered and with but little staking. The plants, of which there must have been some twelve dozen or more, were as yet hardly at their best, and will make a fine display for many weeks to come. A large and well-grown group of Begonia Moonlight (white) was also shown.

Mr. J. Russell, Richmond, staged a highly attractive lot of stove plants, Crotons, Alocasias, Dracenas, Pandanus, Marantas, Cordylines, and other things of like character, forming a group of exceedingly useful material, and for general decorative work in particular. The arrangement, too, was well carried out. A basket of Cupressus erecta aurea was also from Mr. Russell. It is a compact and small-growing kind. Silver Banksian medal.

Begonia Turnford Hall was shown by F. D. Lambert, Esq., Moor Hale, Cookham (gardener, Mr. John Fulford). The plants were well grown and flowered.

Messrs. W. Wells and Co., Limited, Redhill, set up a grand lot of Chrysanthemums of all sections of the flower, forming a group as varied and interesting as could be desired. In the background the single kind, Oldfield Glory, a pale sulphur tone, was very charming, and showed to advantage with reds and crimson on either side. Some of the large flowers included Mrs. Pockett, W. Duckham, silvery rose; and Mrs. T. Wells, crimson. Among singles Miss Holden, yellow; Miss M. Anderson, Miss J. Ferguson, Lady Smith, and Annie Tweed, crimson, were among the best. To complete a very fine lot a margin of the showy Pompon sorts was arranged, and in their many and diverse shades made a very pleasing whole. In another direction Mr. Wells had some half dozen boards of choice specimen blooms, such as Miss Byron, Mrs. Pockett, W. R. Church, crimson; Mrs. Alexander McKinley, orange; Lord Ludlow, a monster flower, yellow, margined crimson; Mrs. G. Mileham, fine rose; Matthew Smith, orange; Mme. Herrewege, Lord Alverston, dark crimson, very glossy; and many more. A feature of this lot was a margin of some two dozen flowers of the yellow Mrs. Pockett; it is a grand kind without doubt. Silver-gilt Flora medal.

Cut Chrysanthemums were well shown by Percy R. Dunn, Esq., Brockley Park, Forest Hill, and reflected much credit for the many good blooms. Some of the best were Miss Hetty Dean, white; Mrs. Greenfield, gold; Miss E. Fulton, the white; Mrs. G. Mileham, Sir H. Kitchener, George Lawrence, and Master C. Seymour. A pretty effect was secured by grasses and Asparagus Sprengeri intermixed with the blooms. Silver Banksian medal.

Mr. James Hudson, Gunnersbury House, Acton, contributed Cactus Dahlia in variety, showing their long-contained flowering this year. Many of the flowers were very good. A basket of Mesembryanthemum roseum was also shown.

Mr. Fyfe, Lockinge Park, contributed Ipomoea rubrococulea in the cut state, a beautiful gathering of flowers of this old Mexican climber so rarely seen now. Vote of thanks was accorded.

Kalanchoe marmorata, a plant of succulent growth, 4 feet high, with roundish ovate opposite leaves irregularly marbled with purple. The flowers are white and long, having a striking resemblance to the Nicotiana. Botanical certificate. From Messrs. Veitch and Sons, Limited, Chelsea.

#### CERTIFICATE PLANTS.

The following received an award of merit:—

*Carnation Duchess of Portland.*—A good tree variety with fine flowers of a soft pink hue. The variety is deliciously scented. From Messrs. William Cutbush and Son, Highgate.

*Chrysanthemum Harry Shrimpton.*—Gold, and copiously covered with chestnut red; a large imposing flower. From Mr. W. Seward, Hanwell.

*Chrysanthemum Mrs. J. Seward.*—A golden incurved variety of dwarf habit. From Mr. W. Seward, Hanwell.

*Chrysanthemum T. Wright.*—A grand crimson, lightly tipped gold on the centre florets. The florets are broad and massive, and the flower is of great size. Shown by W. Wells and Co., Redhill, Surrey.

#### AWARDS.

The list of awards given by the fruit and vegetable committee on the 4th inst., as published in our issue for the 5th inst., was incomplete. Awards of merit were given to each of the following:—

*Langley Bullock.*—From Messrs. James Veitch and Sons, Limited, Chelsea.

*Raspberry November Abundance.*—A very fine autumn fruiting red variety, the result of a cross between Superlative and Catawissa. Also from Messrs. James Veitch.

*Apple Tanptin.*—A fruit of excellent quality. Shown by Mr. Easham, Bassaleg.

*Grape Imperial Black.*—From Mr. J. H. Goodacre, Elvaston Gardens.

*Christmas Rhubarb.*—This variety was shown by Messrs. Sutton and Sons, Reading, and also by Messrs. Veitch, Chelsea.

#### BRISTOL AND DISTRICT GARDENERS' ASSOCIATION.

A most successful meeting of this society was held at St. John's Rooms, Redland, on Thursday evening, the 30th ult., when Mr. J. H. Jarvis, of the Newport Gardeners' Association, gave a most exhaustive lecture on the cultivation of pot Roses. Mr. E. H. Einfield occupied the chair, and there was a good attendance. The lecturer divided his lecture into sections, dealing with each in a very practical and masterly way, it being quite evident the subject was in good hands. He fully described every detail required for the successful cultivation of the queen of flowers—the houses most suitable, soils and composts, pruning and general treatment, each receiving very careful and practical description. He strongly advised buying from a recognised Rose grower rather than from the auction markets, the results from which were oftentimes very unsatisfactory.

Mr. Jarvis gave a good selection of the most suitable varieties for indoor cultivation, which he had himself proved excellent sorts. Insect pests he also described, and gave many useful hints for their prevention and eradication. In conclusion, he gave a list of twelve sound hints to be followed for successful cultivation. His lecture was much appreciated by all present, and he was unanimously voted the heartiest thanks of the meeting. Prizes for six cut Roses were awarded, the first going to Mr. J. C. Godwin (gardener, Mr. McCulloch), Mr. A. Baker (gardener, Mr. Orchard) obtaining second. Certificates of merit were awarded to Mr. Ross, for six dishes of Pears; Mr. Gilbert Howes (gardener, Mr. White), for Dendrobiums and Chrysanthemums; Mr. W. Howell Davis (gardener, Mr. Curtis), for Cattleya labiate; Lady Cave (gardener, Mr. Poole), for cut specimens of Bamboos; and to Colonel Goss (gardener, Mr. Shadwick), for a dish of open air Tomatoes and a well-grown Croton.

#### PORTRUSH CHRYSANthemUM SHOW.

THE annual autumn exhibition was held, on the 29th ult., in the spacious Town Hall. The backward season had so little effect upon the blooms, many being but partly expanded, and the entries under such circumstances were naturally fewer in number. Cut blooms demand first notice. In the Japanese section the exhibits were more advanced. For forty-eight blooms, in not less than twenty-four varieties, Mr. C. Penford, gardener to Sir F. Fitzwygram, Bart., Leigh Park, Havant, won the leading award with medium-sized examples of popular varieties, of which the following were noteworthy: Duchess of Sutherland, C. Penford, L. Smith, W. Reid, General Buller, Le Grand Dragon, W. R. Church, Florence Molynex, George Penford, and Mr. Papworth; second, Mr. J. Agate, Brockhampton Nurseries. Mr. J. Love, Park Road, Cowes, won the premier place for twenty-four blooms, in not less than twelve varieties, with a capital set of clean, high-quality blooms; second, Mr. W. G. Adams, 89, Clarendon Road, Southsea. Mr. J. Tosh Robb, Woolston, had the best of three exhibits in the class for twelve blooms; second, Mr. C. E. Creighton, Stanways, Cowes. Incurved varieties were best staged by Mr. Agate and Mr. W. G. Adams, the former winning for thirty-six and the latter for twenty-four. Edith Hughes, D. B. Crane, Miss Annie Hills, C. H. Curtis, and Baron Hirsch were the best blooms. Bonnets of Chrysanthemums made quite a pleasing change, so lightly were the flowers arranged. With a pleasing combination of yellow and suitable foliage, Miss Peel secured the first prize; second, Mr. Sackett. Table decorations, confined to ladies, were quite an important part of the show, so tastefully were they done. Mrs. T. Jeffries, Nursling, Southampton, was first prize-taker; Mrs. W. H. Berry a good second. For a group of Chrysanthemums in pots and foliage plants, Mr. R. Burridge, North End, Portsmouth, was first. Fruit and vegetables were numerous and good.

#### HEREFORD FRUIT AND CHRYSANthemUM SHOW.

THIS, the eleventh annual show, took place on the 5th and 6th inst., in the Shire Hall, Hereford, when Apples and Pears were shown in surprisingly good condition considering the season we have experienced. The classes devoted to the Chrysanthemum and other plants were rather limited in number, but they were generally well filled. A pleasing feature was this year introduced for the first time at Hereford, viz., that of arranging decorative plants amongst the fruit in a class devoted to fifty dishes of Apples.

In this class three exhibitors staged a fine lot of fruit, the King's Acme Nurseries, Ltd., Hereford, being placed first with excellent highly coloured dishes; Messrs. Pewstree Bros., Tillington, Hereford, who came second, also staged very good fruit; Mr. Grindrod, gardener to M. Clive, Esq., Whitfield, Hereford, was a good third, and staged some particularly large dishes of culinary varieties.

Only one exhibitor appeared in a class for thirty dishes of Apples, viz., Mr. R. M. Whiting, Credenhill, Hereford, and he was deservedly awarded the first prize.

Pears were possibly better shown than Apples, Mr. Spencer, gardener to H. C. Moffatt, Esq., Goodrich Court, Ross, being particularly strong in a class for twenty-four dishes, distinct. The second prize was awarded to Mr. Humphries, gardener to the Earl of Chesterfield, Holm Lacy, Hereford, who brought very good fruit. There were also three good exhibits in a class for twelve dishes, Mr. J. C. Jones, gardener to H. G. Lutwyche, Esq., Kynaston, securing first honours with excellent fruits. The second prize was won by Mrs. Blashill, Bridge Sojars, Hereford, Mr. Grindrod, gardener to M. Clive, Esq., Whitfield, being a close third.

#### OPEN ONLY TO AMATEURS.

For twenty-four dishes of Apples, twelve dessert and twelve culinary, Mr. W. Jones, gardener to C. H. Hazlehurst, Esq., Morton Court, Hereford, took the lead; Mr. Wootton, Byford, Hereford, was second.

A class devoted to twelve culinary varieties brought Mr. Nunn, gardener to E. Woodhouse, Esq., Burghill Court, to the front. He staged fruits in very good condition. Mr. W. Jones was second, and Mr. Wootton third.

Eight dessert varieties made an excellent class, Mr. Spencer being the leading exhibitor with a grand set; Mr. Wootton, who was second, staged a very fine dish of Court Pendu Plat amongst others; and Mr. Davies, gardener to W. C. King King, Esq., Bodenham Manor, came third.

Eight exhibitors staged in a class for eight dishes of Pears, first honours being secured by Mr. Currie, gardener to the Rev. G. H. Devonport, Foxley Vicarage, who had excellent fruits; Mr. Loston, gardener to the Rev. H. Brierley, Bridston Vicarage, being a creditable second; and Mr. Fox, gardener to Sir J. Cotterell, Bart., a close third.

Much interest was taken in the packing classes, and Mr. Grindrod and Mr. Froggett (gardener to E. Walker, Esq., Belmont) were the most successful exhibitors.

Champion Classes.—These consisted of the best dishes of various kinds of fruit in the show, Mr. Spencer securing

chief honours for dessert Apples with a grand dish of Ribston Pippin, grown upon a south wall, and also for kitchen Apples, with a highly coloured dish of Peasgood's; Mrs. Blashill, with a remarkably grand dish of Pittaston Dineches, winning that for Pears; while Mr. Grindrod had the best bunch of Grapes in a magnificent one of Gros Colman.

#### VEGETABLES.

Mr. Wilson, Commercial Street, Hereford, offered prizes for ten varieties of distinct vegetables, which brought out six exhibitors, who staged produce of very high quality. Mr. Froggett was first, with a grand lot of clean and well-grown specimens; Messrs. Davies (gardener to W. C. King, Esq.) and Grindrod were very close second and third in the order named.

#### CHRYSANthemUMS.

TWENTY-four Japanese, distinct: First, Mr. Lovelock (gardener to W. Foster, Esq., Brockhampton Court), with excellent blooms of the best varieties; the Rev. H. Brierley, who was second, staged almost equally good blooms. Mr. J. C. Jones was placed first for twelve Japanese, staging a capital stand. With twelve incurved kinds, Mr. Lovelock was placed first, having for his best blooms Mme. Ferlat, Lady Kendal, and Topaz Orientale. Classes devoted to vases of Chrysanthemums and bouquets made a pretty display and brought many fine exhibits.

#### GROUPS OF PLANTS.

These were not numerous, only one being arranged of Chrysanthemums in a space of 10 feet by 7 feet. This was exhibited by Mr. C. Whiting, White Cross Nursery, Hereford, and it was in every way a splendid exhibit. A class was also provided for ornamental foliage and flowering plants, arranged in a space of 10 feet by 7 feet. Here Mr. Fox (gardener to Sir H. S. Cotterell) was first, with a group of great merit; Mr. Whiting, who was placed second, put up a similar collection of plants.

#### TRADE EXHIBITS.

The chief of these were bouquets of distinct kinds of flowers, viz., of Carnations, Orchids, Roses, Chrysanthemums, &c., together with wreaths in variety, from Mr. Wilson, Commercial Street, Hereford. Mr. H. Langston, Warston, Pembridge, brought a fine assortment of Violets in many varieties, and Mr. C. Whiting had groups of Palms and other decorative plants. C. S. Godsall, Esq., Stroud, Gloucestershire, sent a group of well-grown plants, as did also W. Foster, Esq. Mr. Wilson also staged a large collection of exceedingly fine Onions.

#### LIVERPOOL HORTICULTURAL ASSOCIATION.

A MEETING of members of the above was held on the 1st inst. under the presidency of Mr. P. Foster, when Mr. J. Stoner, of Woolton, read a paper on "Vine Culture." Full details were given as practised by himself, and with what results has been shown at the association's shows. A discussion followed, in which Messrs. Foster, Ranson, Carling, Lambart, Benson, Ebwank, and Mercer took part. A cordial vote of thanks was tendered to the lecturer and chairman for their services.

#### WEST OF ENGLAND SOCIETY'S CHRYSANthemUM SHOW.

PLYMOUTH GUILDHALL was the scene of the above society's show on the 4th inst., but the hall affording a far too limited space for staging the numerous exhibits, a large tent was also erected in Guildhall Square. Never before has the show been so largely patronised by exhibitors, and the display presented to the crowds of visitors who assembled during the afternoon was an exceptionally attractive one.

#### OPEN CLASSES.

Forty-eight Japanese blooms: First, Mr. F. S. Vallis, Chippenham. The stand contained some remarkably fine blooms of the best varieties; second, Mr. G. Foster, Teignmouth; third, Mr. G. W. Drake, Cardif.

Twenty-four Japanese blooms: First, Mr. W. M. Smith, Wiveliscombe, with excellent flowers; second, Mr. F. S. Vallis; third, Mr. B. H. Hill, Crediton.

Twelve Japanese blooms: First, Mr. W. M. Smith; second, Sir John Shelley, Crediton; third, Mr. J. E. Gulson, Teignmouth. Six Japanese, white: First, Mr. T. Martin, Plympton, with enormous specimens of Mrs. J. Lewis, the beat in the show; second, Mr. G. Foster, with Mme. Carnot; third, Mr. F. Bradshaw, Lifton, with Mme. Carnot. Six Japanese any other colour: First, Mr. F. Bradshaw, with Mrs. Mease; second, Mr. J. R. Grison, with Le Grand Dragon; third, Mr. G. Foster, with Mrs. Mease. Six Japanese incurred: First, Mr. J. R. Gulson; second, Sir John Shelley; third, Mr. G. Foster. Twelve Anemones: First, Sir J. Jenkins, Mammade; second, Mr. F. Bradshaw. Twelve vases single Chrysanthemums: First, Mr. G. Foster; second, Mr. S. H. Phillips; third, Mr. F. Bradshaw.

Floral display: First, Mr. J. R. Williams, who showed wreaths, crosses, harps, and other devices composed of Orchids, Lilies of the Valley, Arums, Lilium longiflorum, &c.; second, Messrs. Hender and Sons, with artistic shower bouquets and flower-baskets; third, Mr. J. Arnold.

Six specimen Japanese Chrysanthemum plants: First, Mrs. Cottrell, Stoke; second, Sir J. Jenkins; third, Messrs. J. Webster and Sons.

Collection of thirty-six dishes of Apples: First, Sir John Shelley; second, Mr. B. H. Hill; third, Sir J. D. Ferguson-Davie.

#### OPEN TO DEVON AND CORNWALL ONLY.

The president's silver cup for the most effective group of foliage and flowering plants suitable for winter decoration was won by Messrs. T. R. Challice and Sons, Plympton, who staged an attractive group occupying 150 square feet, comprising twenty-three species of Bamboos, the new Asparagus myriocladus, Orchids of many species, Lilies in variety, Carnations, Lilies of the Valley, Bouvardias, Spirea palmata, Tuberoses, with other flowering and foliage plants.

In the miscellaneous group of stove and greenhouse plants

to occupy a space of 100 square feet, the first prize was won by Messrs. J. Webber and Sons. A tall *Phoenic* towered aloft in the centre and was surrounded by Orchids, *Poinsettias*, *Lilium longiflorum*, *Bouvardias*, *Clivias*, *Eucharis*, Lilies, *Cyclamens*, *Silvias*, Begonias, Roman Hyacinths, and Lillies of the Valley tastefully arranged with foliage plants: second, Admiral Parker, Delamore, in whose stand were *Pancratiums*, *Lilium speciosum*, *Arums*, &c.; third, Mrs. Dorner; fourth, Mr. A. Groombridge.

In cut blooms, twenty-four Japanese: First, Mr. T. Martin, with an excellent stand quite good enough to have won in the open class; second, Admiral Sir A. Buller, Plympton; third, General Sir R. Pole-Carew, Anthony; fourth, Admiral Lord Charles Scott, Devonport.

Twelve Japanese: First, Mr. T. Martin, with another first-rate stand; second, Mr. J. F. Winnicot; third, Mrs. Dorner.

Six Japanese: First, Mr. T. Martin; second, Admiral Sir A. Buller; third, Admiral Lord Charles Scott.

There were thirty-two classes for fruit, in which Sir John Shelley carried off the majority of the prizes, followed by Sir J. Ferguson-Davie and Mr. B. H. Hill; and seventeen classes for vegetables, in which Mr. B. H. Hill, Mr. F. Bradshaw, and Sir John Shelley were the most successful exhibitors.

Twenty classes were allotted to pot plants of various descriptions, and there were also classes only open to amateurs and to cottagers.

Few nurserymen could be allotted space, owing to the number of the competing exhibits. Amongst those present Mr. H. Hodge, St. Austell, showed a good collection of excellent blooms of tuberous Begonias, for which he was awarded a certificate of merit. Certificates were also given to Messrs. J. Tomlinson and Sons for fruit; Messrs. Bennett Brothers and A. Groombridge for collections of plants; and Mr. G. Rundle for seedling Chrysanthemums. Messrs. Isaac House and Son, Westbury-on-Trym, Bristol, exhibited well-grown Violets in many varieties, and Mr. W. J. Godfrey showed a series of new Chrysanthemums, mostly of his own raising, among which Sensation, Bessie Godfrey, Godfrey's Pride, Edward VII., W. R. Church, Mafeking Hero, Godfrey's Masterpiece, F. T. Vallis, Mrs. Barkley, and Calvat's Sun were telling varieties. He also showed Carnations and zonal Petargoniums, many of which were very striking.

#### CARDIFF AUTUMN SHOW.

IN THE PARK Hall on the 5th and 6th inst., the above annual autumn exhibition was held, and was in every way a success. Cut blooms were numerous and of high quality, especially in the classes set apart for amateurs and cottagers. Trained plants, too, were of remarkable excellence, quite the best seen this season so far. Orchids were a feature, and so were the non-competitive exhibits from the various trade growers, which added much to the interest of the display. Mr. Gillett, the energetic secretary, saw to all the arrangements in hand, and was ably assisted by an efficient committee, with Mr. Julian as chairman.

Cut blooms were, perhaps, the leading feature. The principal class was that for twenty-four Japanese, distinct, for which handsome prizes were offered. Mr. W. G. Drake, Cathays Terrace, Cardiff, secured the leading award with large well-proportioned blooms of Mrs. J. Lewis, T. Carrington, Australie, Mme. Herrewege, Rev. W. Wilks, Mme. G. Brant, Le Grand Dragon, Mme. Carnot, M. Hoste, M. Chenon de Leche, W. R. Church (very fine), Mme. L. Kemy, &c. Mr. J. Howe, gardener to G. Williams, Esq., Manor House, Cardiff, was second, with Mr. C. Ritchings, gardener to the Misses Baird, St. James, West Malvern, a close third.

Incurved varieties were especially well staged, Mr. Drake winning, not too easily, from Mr. Ritchings, both displaying quality in their exhibits. Such varieties as Globe d'Or, C. H. Curtis, Hanwell Glory, Miss A. Hills, and Lady Isabel were seen in good character.

With twelve Japanese, four competed. Mr. H. Townsend, gardener to H. Pitt, Esq., Abergavenny, was the leading prize winner; Mr. R. Milner, gardener to Miss Talbot, Margam, second.

Local classes were a strong feature. For twenty-four Japanese, in not less than twelve varieties, much keenness in competition was apparent. Mr. E. A. Parsons, gardener to Mrs. J. D. Gunn, Newport Road, Cardiff, was the most successful with excellent blooms of Lord Ludlow, W. R. Church, M. Chenon de Leche, and M. Louis Remy; Mr. J. J. Graham, gardener to A. T. Stephens, Esq., Penarth, was a close second; Mr. H. A. Allen, Penarth, third.

For twelve Japanese, Mr. Graham also won premier award; Mr. A. F. Hill, 10, Oakfield Street, Cardiff, was a close second, W. R. Church being uncommonly good in this stand.

The best of twelve incurved were staged by Mr. Parsons.

For six Japanese, one variety, Mr. Graham staged Mrs. J. Lewis in excellent condition, winning easily from Mr. Parsons, who also showed this variety.

For twelve Japanese there was keen competition, Mr. A. H. Hill winning from five others with grandly developed blooms; Mr. Allen second. Cottagers classes were extremely fine.

Single-flowered varieties were grandly staged. For six bunches, distinct, three trusses of each, Dr. T. Wallace secured the coveted position with splendid flowers; Mr. Stephens second.

Mr. W. Treseder, Cardiff, was almost impregnable in the floral department, winning first prize for a wreath, cross, bouquet, sprays, &c., with exhibits well sustaining his reputation.

Mr. Ralph Crossling, Penarth, won the first prize for a bouquet of Chrysanthemums, showing a superb arrangement of *D'Or*, Ferns, &c.

Plants, although not numerous, were noteworthy for their excellence, especially the trained examples of that typical incurved variety C. H. Curtis, from Mr. T. Binden, gardener to Dr. T. Wallace. As a single-flowered specimen, Mr. Binden staged Miss Rose, furnished with 1,300 fully developed blooms, and carried off the premier award.

Mr. W. Treseder was placed first for a circular group of Chrysanthemums, nicely edged with Ferns, &c. Mr. W. Hatherdale, Roath, occupied a similar position in a smaller class, with capital plants for the purpose.

Exhibits of a non-competitive order were numerous, adding greatly to the display. Messrs. Cypher, Cheltenham, with Orchids; Mr. Easham, Bassaleg, a capital collection of fruit; Mr. W. Treseder, *Cactus Dahlias*; Mr. S. Treseder, Roses; Messrs. Clibran, Altringham, fruit.

#### TORQUAY CHRYSANTHEMUM SHOW.

ON THE 5TH INST. THE TORQUAY Gardeners' Association held their annual autumn show, but owing to a succession of wet days on the dates of previous shows, which limited the attendance, and to the poor support given by residents to the association no funds were available for prizes. The day previous, at the West of England Society's show at Plymouth, over £200 was offered in prizes, more than five hundred names appearing on the list of subscribers, and it is certainly a slur on the fair fame of Torquay, whose hills are studded with villas surrounded by beautiful gardens, that the Gardeners' Association, which endeavours to add to the attractions of the town by organising spring and autumn flower shows, should be hampered by reason of inadequate support. Perhaps systematic canvassing might remedy the evil, but certainly some steps should be taken to induce residents to aid in establishing the annual flower shows on a sound financial basis. Despite the absence of prizes a fine display was provided in the large hall of the Bath Saloons, the supporters of the association contributing attractive groups of Chrysanthemums, stove and greenhouse plants, as well as stands of cut blooms fully up to exhibition form. With the exception of four special prizes for a vase of six Chrysanthemums, for six single Primulas, and two for vegetables, all the exhibits were honorary, and it redounded greatly to the credit of all concerned that the show was in no way inferior to those of former years.

Nurserymen added much to the brightness of the scene by their stands of flowers and fruit. Messrs. Curtis, Sanford and Co., Devon Rosary, Torquay, showed over 200 Roses cut from the open, remarkably fine for November, as well as large-flowered Chrysanthemums, *Bouvardias*, Begonias, retarded Lilies of the Valley, *Spiraeas*, *Lilium longiflorum*, Palms, &c. From their fruit farm at Cockington came a fine collection of Apples, Cucumbers, Tomatoes, Strawberries from the open ground, flowering Laburnum, and Violets in variety.

Messrs. Robert Veitch and Son, Exeter, showed hardy flowering plants in great variety. Mr. W. E. Smale, Torquay, had Chrysanthemums, *Cinerarias*, Carnation, Mrs. Lawson, *Bouvardias*, *Streptocarpus*, as well as a good selection of the best *Cactus Dahlias* and fine blooms of tuberous Begonias. Mr. W. J. Godfrey, Exmouth, staged a number of Chrysanthemum novelties, among which were many beautiful varieties. He also showed a collection of zonal Pelargonium and Carnation blooms. Mr. T. Heath, Kingskerswell, exhibited Violets both cut and in pots, all the leading varieties being shown. Good groups of miscellaneous plants were staged from the gardens of Mr. Bell, Mrs. Hassall, Mrs. Bundock, and Dr. Quick, in the latter stand being a white sport of Chrysanthemum *Waban*. A large and very excellent central group of Chrysanthemums was contributed by Dr. Ford Edgerton. Splendid Maiden-hair Ferns were sent from the Erith House Institution, and fine collections of fruit were furnished from the gardens of residents in Torquay and the surrounding neighbourhood. Four prettily decorated dinner-tables attracted considerable attention, and as prize cards were conspicuous by their absence, partisans were enabled to uphold the superiority of their choice.

#### EXETER CHRYSANTHEMUM SHOW.

THE ABOVE SHOW was held in the Victoria Hall, Exeter, on the 6th inst., under the auspices of the Devon and Exeter Horticultural Society, and resulted in keen competition, especially in the cut bloom and fruit departments.

Chrysanthemums in pots in circle 10 feet diameter: First prize, Mr. W. Brock; second prize, Mrs. Savile. Chrysanthemums in circle, 8 feet diameter: First prize, Mr. M. Farrant. Chrysanthemums staged in semi-circle: First prize, Mr. C. M. Collingwood (this group was also awarded the National Chrysanthemum Society's certificate of merit); second prize, Mr. W. Brock.

Group of miscellaneous plants: First prize, Mr. W. Brock, for an artistically arranged group with a tall *Cocos flexosa* in the centre, surrounded by Bamboos, Crotons, Asparaguses, and Maiden-hair Ferns, brightened by *Poinsettias*, Orchids, &c.; second prize, Mr. M. Farrant.

#### CUT BLOOMS.

Thirty-six Japanese: First prize, Mr. F. S. Vallis, the winner both at the Royal Aquarium and at Plymouth, with magnificent flowers of the leading sorts. Of his blooms Mme. Waldeck Rousseau and Kimberley in the back row, and Mrs. Vallis and Matthew Smith in the front row, were especially fine; second prize, Mr. W. Macadam Smith; third prize, Mr. H. N. Harrison.

Thirty-six Japanese, twelve distinct varieties shown in vases: First prize, Sir D. Duckworth-King; second prize, Mrs. Hammond-Spencer.

Eighteen Japanese: First prize, Sir John Shelley; second prize, Mrs. Hammond-Spencer; third prize, Mr. B. H. Hill. Six Japanese, white: First prize, Mrs. Hammond-Spencer, with Mme. Carnot; second prize, Sir John Shelley, with Mrs. J. Lewis. Six Japanese, yellow: First prize, Rev. E. Heathcote, with Kimberley; Mrs. Mease, the primrose sport of Mme. Carnot, was disqualified for not being yellow. Six Japanese, any other colour: First prize, Mr. T. Kekewich, with Lady Ridgeway.

While on the subject of cut blooms mention must be made of an excellent stand of twelve Japanese shown by Mr. W. L. Jones in the class for amateurs and cottagers. This stand was deservedly awarded the National Chrysanthemum Society's certificate of merit, as the blooms were of enormous

size and in perfect condition. Two classes were devoted to baskets of autumn foliage and berries, and one to baskets of cut Chrysanthemums, all of which were well filled with tasteful arrangements. There were over fifty classes for fruit, of which there was a splendid display. Sir John Shelley carried off the premier honours, followed by Mrs. Hearn, Mr. T. Kekewich, and Mr. B. H. Hill; while among the other winners were Sir J. Ferguson-Davie, Sir D. Duckworth-King, Lord Poltimore, and Sir J. Kennaway.

Messrs. Isaac House and Son, Westbury-on-Trym, Bristol, were awarded the society's certificate of merit for a collection of Violets, amongst which were La France, Luxonne, Princess of Wales, The Czar, and Semperfiorens, a pale blue Violet, said to be in bloom for eight months out of the twelve, and Mrs. J. J. Astor, Marie Louise, and Lady Huine Campbell of the doubles.

Messrs. Robert Veitch and Son, Exeter, had a collection of new *Cactus Dahlias*, of which Mrs. E. Mawley, Lucius, Night, and Radiance were particularly noteworthy. They also staged *Parochetus communis major*, blue Primroses, *Vitis Coignetiae* (very finely coloured), *Nerines*, *Acacias*, *Lilium*, *Ceanothus*, *Primulas*, *Skimmias*, *Veronicas*, *Physalis Franchetti*, and other plants.

#### READING AND DISTRICT GARDENERS' ASSOCIATION.

ABOUT 120 members assembled at the last fortnightly meeting of the above association, when Mr. James C. House, of Westbury-on-Trym, gave a lecture on "Sweet Peas." In introducing the subject the lecturer asked the question: "What are the qualities of the Sweet Pea which give it such a high position amongst flowers?" and answered it as follows: The wide range of colour; the softness of its tints: perfume; durability; grace of form; length of flowering season; and that the seed was within the reach of all. Passing on to varieties, he recommended as the best in their various colours Salopian (crimson), Lord Rosebery (rose and carnine), Prima Donna (pink), Navy Blue (deep blue), Countess Cadogan (medium blue), Dorothy Tennant (mauve), Miss Willmott (salmon), Countess of Aberdeen (blush), Hop, Mrs. Kenyon (yellow), Duke of Westminster (violet), Black Knight (bronze or maroon), Lady Grisel Hamilton (lavender), Dorothy Eckford (white), Lottie Hutchins (fancy), &c. An interesting discussion followed, in which the President, Messrs. Stanton, Powell, Neve, Hinton, &c., took part.

The exhibits were numerous and interesting. Honorary: Mr. G. Stanton, Park Place, made a splendid as well as an instructive exhibit of a collection of Apples and Pears, consisting of typical specimens, each correctly named, of fifty varieties of the former and fifty of the latter, also a basket and two pedestals, standing about 2½ feet high, of beautiful specimens of Sweet Peas, illustrating in a remarkable manner the lateness as well as the mildness of the present season. Mr. Barnes, of Bear Wood, staged three magnificent Melons (not yet named); Mr. J. Pound, of Caversham, two dishes of Apples, splendid fruits for the season; Mr. Tunbridge, Medmenham, a brace of Cucumbers whilst for the cultural certificate Mr. J. Wicks, the Gardens, Broad Oak, staged six well-grown specimens of *Eggonia Turnford Hall*, and Mr. House, of Oakfield Gardens, a seedling Chrysanthemum. The certificate was awarded to the Begonias.

The prizes won in the recent essay competition were presented to the successful competitors as follows:—Seniors: "All Phases of Pruning in connexion with Hardy Fruit Culture."—First prize, value 40s. (mathematical instruments and microscope), Mr. C. P. Cretchley, the Gardens, The Honeys, Twyford; second prize, 30s. (clock), Mr. G. Hinton, the Gardens, Walmer, Reading. Juniors: "The Best Means of Maintaining a Supply of Vegetables all the Year Round."—First prize, 30s. (six volumes of "Wright's Fruit Growers' Guide"), Mr. W. G. Wade, the Gardens, Bear Wood; second prize, 20s. (mathematical instruments), Mr. A. Etherington, the Gardens, Park Place. Four new members were elected.

#### CAMBRIDGE AUTUMN SHOW.

THE AUTUMN SHOW in connexion with the Cambridgeshire Horticultural Society was held in the Corn Exchange on the 5th and 6th inst., and proved one of the most successful the society has held for many years.

#### CHRYSANTEMUMS.

Mr. A. Matthews was first for a group of plants, having mostly Japanese Chrysanthemums, Miss A. Newman being second.

For the best Japanese blooms, Messrs. Willers and Bond were the most successful, and the same exhibitors were very often leading in the incurved section. The decorated tables were a pretty feature, the most successful exhibitors being Mrs. J. E. L. Whitehead, Dr. Sandys, and Mr. P. L. Hudson.

Mr. E. B. Forster was the fortunate winner of the prize for the best Japanese bloom, having a very fine Mrs. H. Weeks; and for the best incurved, Mr. A. J. Thornhill had a grand flower of Lady Isabel. The vase classes were a leading feature. There were some splendid blooms staged. The best incurved in vases were staged by Messrs. Linton and Briscoe, and the Japanese by Mr. W. Bond, Sir A. W. Marshall, and Mr. A. Matthews.

In the class for thirty-six blooms, Japanese, there were some grand stands staged, the flowers in this section being notable for their good form. Mr. W. Bond had the premier award, Mr. E. B. Forster being second. For the best twenty-four blooms, incurved, Messrs. A. J. Thornhill, W. A. Briscoe, and J. Linton took the prizes in the order named. In the smaller classes for members' prizes there was less competition, but good blooms were shown. Here we found several new names to those previously noted, Messrs. Foster, Bond, Stables, Linton, and Dobbs being the chief winners in these classes.

#### FRUIT.

Fruit was a leading feature and was well shown. Special mention must be made of the collection of thirty varieties of Apples and Pears. Lord Clifden was first; but

very closely followed by Mr. J. H. Ridgewell, who lost a few points in the cooking Apples; Mr. J. W. Burkett being third. In the smaller collections the fruit was remarkable for its perfect shape and beautiful colour. For twelve varieties, Messrs. Adeane, Briscoe, and Barnard were the winners. For six varieties, Messrs. Vawson, Harnard, and Burkett. For three dishes, Messrs. Vawson, Matthews, and Burkett; and in the dessert class, Messrs. Harnard, Adeane, and Viscount Clifden had splendid dishes. For single dishes there was a good competition and splendid fruits were staged.

Pears were very good: there were many classes for these fruits, and many of the exhibitors named above were again the prize winners. In the classes for flavour, Mr. J. H. Ridgewell had the best fruits; all those who won having Doymone du Comice. Messrs. Briscoe, Burkett, and Linton led in most cases.

Grapes were well shown, and certainly deserved more space. For the best Muscat of Alexandria, Mr. C. R. W. Adeane had grandly coloured bunches; Messrs. Linton and Hudson being respectively second and third. Mr. J. Linton had the best any other white variety. In the class for the variety Alicante there was a strong fight for the premier award, Mr. Hudson being first with grand bunches; Mr. Adeane second; and Mr. Matthews third.

Vegetables were equal in quality and quantity to the other exhibits and well staged, there being an absence of coarseness often seen at this season. For the last twelve kinds, Mr. A. J. Thornhill was first; Mr. Ridgewell being second. For twelve varieties of Potatoes, some splendid examples were shown; Mr. Ridgewell being a good first. In the class for six dishes, the same exhibitor was first; Messrs. Ginn, Hutchinson, and Matthews being the other prize takers.

The secretaries and committee deserve every praise for the general arrangements made at this grand autumn show.

#### NEWPORT CHRYSANTHEMUM SHOW.

No better site in which to hold an autumn exhibition could be wished for than the Gymnasium in this town. Ample space and light are assured, with a pleasant promenading space for the visitors. The show in question, which was held on the 6th inst., was, perhaps, a little smaller in extent, but this defect was made up in point of quality. Groups of Chrysanthemums were not numerous, but creditable. Mr. J. Pledger, gardener to H. J. Davis, Esq., won premier position with suitable plants, tastefully interspersed with foliage plants; Dr. Thomas was second, but little behind the former. For a smaller group, Mr. K. Long, gardener to W. J. Dawson, Esq., won somewhat easily. With a capital lot of Orchids, Ferns, Palms, and Crotons, Mr. Phillips won the premier position for a group of miscellaneous plants arranged for effect.

Cut blooms were numerous. The leading class was that for twenty-four Japanese, which carried with the challenge cup offered a substantial cash prize also. Mr. J. Butt, gardener to Mrs. Williams, Newport, was an easy first with heavy blooms. The following were of the best: Australie, Mme. Carnot, Simplicity, Matthew Smith, Phœbus, Mrs. J. L. McKellar, Calvat's 99, and M. Louis Remy (grand); Mr. J. J. Graham, gardener to A. T. Stephens, Esq., Newport, a good second; Mr. Drake, Cardiff, third.

For twelve Japanese, Mr. J. Butt won first place with examples similar to those in his leading stand of twenty-four; second, Mr. G. Richardson, gardener to Sir H. M. Jackson.

Orchids, Primulas, plants for table decoration, and fruit were all freely contributed and neatly staged, adding much to the beauty of the show.

#### SOUTHAMPTON SHOW.

This annual exhibition, held in the Victoria Hall on the 4th and 5th inst., proved a great success, exhibits being close in point of quality and competition keen.

#### OPEN CLASSES.

Plants: For the best collection of Chrysanthemums arranged in a limited space, Mr. C. Hosey, gardener to J. C. E. D'Esterre, Esq., Elmfield, Southampton, secured first prize with dwarf plants carrying very good blooms; Mr. B. Henley, Masonic Hall, Woodston, and Mr. T. Hall, gardener to Sir S. Montagu, South Stoneham House, were second and third respectively.

Cut blooms: The principal class was that for Japanese, twelve varieties; three blooms of each, staged in vases, for which the Victoria Challenge Trophy was offered, accompanied by a money prize. There were three competitors, the winning exhibit being shown by Mr. G. Hall, gardener to Lady Louisa Ashburton, Melchet Court, Romsey, his blooms being very creditable; Mr. L. Dawes, gardener to Mrs. Ogilvie, Hambleton, was a close second; third, Mr. C. Hosey.

For twenty-four Japanese, four competed, the best being shown by His Majesty the King, Osborne (gardener, Mr. T. Nobbs); Mr. G. Hall was second; Mr. J. Wasley, gardener to J. B. Taylor, Esq., Sherfield Manor, Basingstoke, third.

In the class for eighteen Japanese there were five entries, the prizes again going to Messrs. Nobbs, Hall, and Wasley. Mr. Dawes was first for twelve Japanese, with good examples; Mr. Nobbs was second.

Entries for incurved were scarce. For twelve, Mr. G. Hall was an easy first with medium-sized blooms of Louisa Giles, Mrs. R. C. Kingston, C. H. Curtis, Baron Hirsch, &c.; second, Mr. J. Love, Park Road, Cowes, Isle of Wight, whose Falene won premier award for an incurved bloom.

Gentlemen's gardeners and amateurs in the classes allotted to them made a good display. For eighteen blooms of any kind, not more than two of any one variety, there were four competing, the premier stand being shown by Mr. E. Brown; Mr. M. Hodgson, Morton House, Kingsworthy, second. For twelve blooms, seven competed, Mr. Brown again leading, with similar varieties to the previous stand; Mr. Tragett, Awbridge Danes, Romsey, second.

In the class for four varieties Japanese, three blooms of each, staged in vases, Mr. Brown was again first with really

fine examples; Mr. H. E. Sugden, Ingersley, Chilworth, second. The premier Japanese bloom was Miss Alice Byron belonging to Mr. J. Dawes.

Miscellaneous plants arranged for effect were not numerous. Mr. E. Wills, The Nurseries, Winchester Road, Southampton, was first; Mr. T. Hall second.

For the most tastefully arranged vase of Chrysanthemums, foliage, grasses, &c., open to ladies only, Miss Minnie Snellgrove, 10, Oxford Road, Southampton, was first with a charmingly arranged exhibit; Mrs. Jeffrey, Nursling, Southampton, second. For a basket of autumn leaves and berries, five competed, the whole effect being good and arrangement excellent; Miss Wadmore, Brook House, Basingstoke, was first, and Mrs. Jeffreys second.

Fruit was plentifully staged, but space forbids mention of the individual classes.

Mr. C. S. Fudge had, as usual, all the arrangements in perfect order; he has had almost a lifelong experience of horticultural exhibition management as secretary.

#### ALTRINCHAM AND DISTRICT CHRYSANTHEMUM SHOW.

The exhibition held on Friday and Saturday week in the spacious Drill Hall, Hale, was marked by many notable features, the first being the groups arranged for effect, and for which five competed. The first prize and silver cup given by the President (Sir W. Pollitt, J.P.), were won by Mr. T. Johnson, gardener to T. H. Edward, Esq., Eastcill, Bowdon, the plants being dwarf, fresh and good; a capital second came from Mr. Leah, gardener to S. Thompson, Esq., Brentwood, Altringham; third, Mr. J. Corbett, gardener to J. Thompson, Esq., Beech Bank, Bowdon. In another section for groups, Mr. J. Royle, Britannia Grove, Sale, was first. Decorative and miscellaneous plants were excellent, but the numerous classes will not permit of names being given. There was a handsome silver cup presented for twelve incurved and twelve Japanese; Mr. J. Holbrook won with the blooms. Incurved flowers were very weak, as indeed they were throughout the show.

In the open competition for the same number, Mr. J. Mottram, gardener to Mrs. Bodin, Beech Mount, Bowdon, was the victor, with excellent flowers; second, Mr. A. H. Hall, gardener to J. C. Waterhouse, Esq., Collar House, Prestbury. Some specially good Japanese were in the twelve class won by Mr. Ashworth, gardener to T. Thompson, Esq. Mr. Calderbank, gardener to W. J. Crossly, Esq., Altringham, had several more than promising seedling Japanese.

Floral decorations were superb, whilst fruit, more especially Grapes, was largely represented. Mr. J. Robson, Bowdon, had a rich assortment of miscellaneous plants, and Mr. W. Wells, Earlswood, Surrey, many new Chrysanthemums, being honoured with certificates for the grand coloured S. T. Wright, and a bronzy red incurred of fine petal named Miss R. Hunt. The best Japanese bloom was Mrs. Barclay, from Mr. J. Holbrook; and best incurred, Mme. Ferlat, from Mr. Mottram.

#### TOTTENHAM AND EDMONTON CHRYSANTHEMUM SHOW.

The fourteenth annual display of this society was held in the Town Hall, Edmonton, on the 6th and 7th inst., and, considering the acknowledged backwardness of the season, the promoters of the exhibition have every reason to be satisfied with their efforts. One of the leading classes was that for a group of Chrysanthemums arranged in a semi-circular space. A handsome lot of plants, bearing large and clean blooms of good colour and nicely disposed, secured premier honours for Mr. W. J. Reed, gardener to Rev. Benton Jones, The Vicarage, Tottenham. Second prize was awarded to Mr. W. Welfare, gardener to Mr. J. Pedley, J.P., Trafalgar House, with somewhat formal arrangement, although the flowers were good, and third prize went to Mr. F. Gartham, Strand Union School, for a pretty lot of flowers which wanted more colour. Specimen plants are always well shown at this exhibition, and on the present occasion, for four trained plants, Mr. G. W. Hendon, gardener to Mr. J. Cloundsley, J.P., White Hart Lane, Tottenham, was a good first; Mr. Welfare was placed second.

Twenty-four Japanese blooms, in not less than eighteen varieties, formed the principal contest in the cut bloom classes. In this instance Mr. Welfare triumphed, winning with good flowers; Mr. Hendon was second with a smaller set altogether.

Twelve blooms Japanese, distinct, saw Mr. Welfare again to the fore with a capital lot of blooms of good colour. Mr. Hendon was again second with smaller though pretty blooms, succeeded by Mr. A. H. King, gardener to Mr. J. Bailey. A class for twelve blooms large-flowered Anemones, in which Japanese Anemones were allowed, Mr. F. J. Golding, Lee Villa, Lansdowne Road, Tottenham, was placed first for a rather poor lot of flowers; Mr. G. H. Thurlby, 13, Argyle Road, Tottenham, following the first prize lot closely. A similar class for six blooms, distinct, was infinitely superior in point of quality to the larger class. In this instance Mr. J. G. Caines, 92, Birkbeck Road, Tottenham, was awarded first prize for a nice lot of well-developed flowers with good discs. A good second was found in Mr. Hendon, with a very bright lot of flowers, and Mr. Golding was third.

The quality of the amateur exhibits was distinctly good, vying with the professional exhibits for popular favour. For twelve blooms Japanese, distinct, a superb lot of flowers won first prize for Mr. F. L. Gray, Fernleigh, Lower Edmonton. His best flowers included Mrs. George Mileham (best bloom in the show). A smaller set secured second prize for Mr. M. England, 107, Silver Street, Edmonton, followed by Mr. Caines, third. For six blooms Japanese, distinct, the popular secretary, Mr. G. H. Thurlby, was found in the coveted position. His blooms were neat, clean, and even; second prize was won by Mr. H. Tyrell, 21, Nassau Road, South Tottenham, with larger though somewhat rough flowers, and third prize went to Mr. R. Norman, 15, Northumberland Grove, Tottenham.

M. Louis Remy was the premier bloom in the open classes.

and was exhibited by Mr. Welfare. In the amateur division a magnificent flower of Mrs. George Mileham was the premier bloom, and was shown by Mr. Gray.

Fruits and vegetables were staged, the latter freely and in excellent condition, and these, together with Chrysanthemums in vases, made an interesting and praiseworthy exhibition.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

THE Floral Committee of this society met together at the Royal Aquarium, Westminster, on Monday afternoon last, Mr. D. B. Crane (in the chair) and a very fair attendance of members present.

Novelties were not by any means numerous, and of these several failed to reach the desired standard of quality. Those receive recognition were

*Mrs. A. R. Knight*.—A large, deeply-built, reflexed Japanese bloom, with fairly long petals of medium width. The lower petals are broader, curling, and slightly incurving at the ends. The lower part of the flower is reddish crimson on the inside of the florets, with a bronzy reverse, but the upper portion of the bloom is a glorious rich golden-yellow. First-class certificate to Mr. N. Molyneux, Rookesbury Park, Hants.

*Mrs. J. Seward*.—This is a very large, massively-built incurved bloom of neat and even form, having petals of medium width neatly incurving, and building up a bloom of globular form; colour pale yellow, tinted buff. First-class certificate to Mr. W. Seward, Hanwell. The committee also wished to see again

*Madge Creagh*.—A medium-sized incurved bloom, of good form, with neat and well-defined incurved petals, building up a pretty and even flower; colour buff-yellow, tinted rosy bronze on the lower portion of the bloom.

*Mildred Lyne*.—A valuable sport from incurved Mr. H. J. Jones, and equal in size and substance to the parent bloom. The blooms have a yellowish centre, and are rosy bronze on the lower portion of the flowers; inside colouring red. This should prove an acquisition to the incurved section.

**THE CORN EXCHANGE CHRYSANTHEMUM SOCIETY.** This society, which is composed of members of the Corn Exchange and their friends in the City who take an interest in the Chrysanthemum, combines charitable work with a very attractive though small exhibition that filled one of the large rooms of the restaurant by the side of the Corn Exchange on the 10th inst. The towers are staged by 11 a.m., they are then judged, the public are admitted by making a small payment, and at 3.30 all the exhibits are sold for the benefit of the Corn Exchange Benevolent Society.

The four first classes out of the nine comprising the schedule of prizes are confined simply to members of the Corn Exchange, and two prizes were awarded in each. The principal prize-winner in these was Mr. William R. Clarke, Loughton (gardener, Mr. F. King). In Class 1, twelve distinct Japanese were shown; Mr. Clarke taking the first prize with some very good flowers; Mr. F. W. Smith, Weybridge (gardener, Mr. T. Buckmaster), was a good second.

In the class for twelve blooms, any varieties, Mr. Clarke was again placed first. He staged four incurved varieties, namely, Mme. Ferlat, Lady Isabel, Chrysanthemite Bruant, and Mme. E. Roger, the green tint of which proved of great interest, and some fine Japanese. With six blooms of Japanese, Mr. Clarke again came to the fore; Mr. F. W. Smith was again second. For six blooms of any variety, Mr. Clarke secured his fourth win with very fine blooms of incurved varieties; Mr. Smith came in second once more with six Japanese.

The non-members of the Corn Exchange competing were more numerous than the members. There were seven stands of twelve blooms. Mr. R. Kenyon, Monkham, Woodford, was placed first with excellent Japanese blooms; Mr. F. S. Holland (gardener, Mr. T. Stevenson) was a close second.

With twelve blooms, distinct varieties, Mr. Holland was again first, having on the front of his board four finely developed incurved varieties as well as Japanese. For six blooms of Japanese, Mr. Holland gained another first prize; Mr. R. Kenyon was second. For six blooms, distinct varieties, Mr. Holland again won with six excellent incurved varieties; Mr. H. Ferguson was placed second, he had six fine Japanese.

The best six blooms shown in a vase came also from Mr. Holland, and Mr. F. W. Smith was second.

A silver bowl offered for the best twelve blooms in the four classes, open to members of the Corn Exchange, was awarded to Mr. Clarke; and a silver cup offered in the four non-members classes to Mr. Holland. Of miscellaneous exhibits Messrs. T. Tiffen and Co., Cannon Street, sent a large and very handsome bouquet composed of Liberty and other Roses, Orchids, Lilies, &c. Mr. D. Grimslade, a member of the committee, sent ten pretty plants of Cattleyas, and Messrs. M. Longman and Co., florists, Mark Lane, a decorated floral car, which was greatly admired.

#### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE usual monthly committee meeting of this society was held at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday evening last. Mr. C. H. Curtis presided. Nine members were reported on the sick fund, the amount of sick pay for the month being £31 7s. Seven new members were elected, making a total of eighty-six this year up to the present time. The secretary was authorised to obtain 3,000 circulars for distribution.

**Horticultural Club.**—After the house meeting of the club on Tuesday next, at 6 p.m., Mr. Henry Stevens, of Covent Garden, will show a series of lantern slides prepared from his flower and other photographs. This promises to be an exceptionally interesting evening.

## THE HORTICULTURAL HALL.

### THE PLANS.

**W**ITH eager anticipation we opened the book of plans of the Royal Horticultural Society's proposed buildings in Vincent Square.

We deeply regret that we can only view them with a sense of disappointment. It was a rare chance of doing something that should be in the first place of absolute utility and convenience, and, in the second, should have that simple dignity that would be worthy of the high place now occupied by the Society. The first need has been met, after a fashion; the second, in the plans now before us, has either been ignored or entirely missed. The result is a building entirely commonplace, absolutely wanting in all architectural feeling. The only ingenuity it displays is in giving a maximum of space to the Exhibition Hall, but it is entirely without charm, such charm as is only given by the clever planning, careful detail and fine sense of proportion that the architect who is master of his craft gives to a building, thus endowing it with the qualities of beauty and gracious beneficence while not in the slightest degree depriving it of utility. In the proposed plans what have we? The glass barrel of a railway station, masked by a second-rate railway hotel on the road front!

Possibly the conditions under which the land has been acquired will not allow the building to be brought forward, but the space seems to be much wanted, for the Council Room, and especially the Lecture Hall, are much cramped.

The drive in seems quite needless, and even if the building cannot be brought forward it would be better without the posts and railings, with the space left open. It would be quieter and more dignified, if the word dignity can possibly be applied to any portion of the proposed building.

In the Exhibition Hall we regret the iron roof and the ugliness of it all, all the more because it is so absolutely needless. Outside we regret the want of simple dignity and proportion, the curiously unhappy fenestration, the lack of every quality a building should possess to be called good. We trust that in future we shall enjoy the shows, but the building—never!

When, during the last two years the question was under consideration, whether the Society should first acquire a new garden or a home

and hall, THE GARDEN strongly advocated the greater need of a new garden. But when the Council decided in favour of the new buildings THE GARDEN could only trust that the decision was a wise one, and desire to do what it might to strengthen the hand of the Society in its new undertaking. We have therefore hoped to see such a building scheme as would do it the utmost credit, and can only express regret when we see plans that we can only think unworthy of the Royal Horticultural Society's position and purpose; wasteful of good money, whose same amount might easily have brought both additional convenience and infinitely greater honour.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

November 22.—Cumberland Chrysanthemum show.

November 24.—Meeting of the National Chrysanthemum Society's executive committee.

December 2.—National Chrysanthemum Society's exhibition at the Royal Aquarium (three days); National Chrysanthemum Society's floral committee meeting; National Amateur Gardeners' Association meets.

December 6.—Meeting of the Société Française d'Horticulture de Londres.

December 9.—Royal Horticultural Society's meeting, Drill Hall, Buckingham Gate.

December 11.—National Rose Society's annual general meeting and dinner, Hotel Windsor.

**Sir Trevor Lawrence, Bart.**, who has rendered such great services to the Royal Horticultural Society and other public bodies, has been honoured by the bestowal of a Knight Commander of the Royal Victorian Order, on the occasion of his Majesty's birthday honours list.

**Royal Horticultural Society.**—The following dates have been fixed by the society for 1903, subject to possible alteration: January 13, January 27, February 10, February 24, March 10, March 24 (Hyacinth and Tulip show), April 7, April 21 (Primula and Auricula Society), May 19 (British Tulip show and conference), May 26, 27 and 28 (Temple flower show), June 9, 25 and 26 (Holland House show), July 7, July 25 (National Carnation show), August 4, August 18, September 1 and 2 (National Dahlia show), September 15, September 29, 30, and October 1 (Fruit and Vegetable show and conference at Chiswick), October 13, October 27, November 10, November 24, and December 15. 1904—January 12, January 26, and February 9.

**A valuable Bullace.**—The fruits of the very fine Bullace, although called a Damson (which it hardly is), when shown at the Drill Hall by Messrs. James Veitch and Sons last month, now named Langley Bullace, having been cooked and very favourably reported upon by Mr. S. T. Wright, obtained an award of merit from the fruit committee at the meeting held on the 4th inst. The variety is an immense cropper, and

there can be little doubt but that if its character as shown on the seedling tree is maintained it will in time be very widely grown for market purposes. The fruit will hang very late, and ripens early in November. Through its aid in the future there should be in commerce a big supply of these fine Bullaces after the Damsons have all been disposed of. The parents as used by Mr. Seddon in effecting the cross some years since were Farleigh Prolific Damson and Orleans Plum. The fruits are of the size of the latter, and produced with all that abundance which characterises the Damson. If slowly, yet surely our hardy fruits are being increased in the most useful way.—A. D.

**Fruit trees on walls.**—On the 12th inst., Mr. W. Crump, Madresfield Court Gardens, Malvern, lectured at the Masonic Hall, Kidderminster, under the auspices of the Kidderminster and District Horticultural Society, on "The Management of Fruit Trees on Walls." There was a large attendance of members, over which the Mayor presided. Mr. Crump gave a most interesting and instructive discourse upon this subject, with which he is so well acquainted, and his remarks were much enjoyed. Mr. W. H. Wilson, of Moor Hall, has promised to give the next lecture on "Digging and Treiching" on December 10.

**The ubiquitous Ampelopsis.**—One reason of the great popularity of Ampelopsis Veitchii or Vitis inconstans seems to have been overlooked by your correspondent "F. H. C." page 340, and that is the fact that it attaches itself to the wall without any support, whereas all the other subjects recommended for associating with it have to be held in position by nails and shreds or some other appliances that necessitate a certain amount of interference with the wall. As many people greatly object to this they plant the Ampelopsis, knowing well that no attention in the way of training or nailing will be needed. It is certainly monotonous to see it planted almost to the exclusion of everything else, but as above stated this is doubtless owing to its self-clinging qualities.—W. T.

**Plums and Cherries.**—In THE GARDEN of the 8th inst. a correspondent asks: "Is it possible to grow successfully stone fruit trees in pots in a viney started on February 1?" Having practised such a system with invariable success for a good many years I can answer most emphatically, "Yes, it can be done." I force several hundred Cherries in pots and tubs every year, placing them in a large viney early in January, and the earliest sorts, Bigarreau de Mai and Guigne d'Annonay, are ripe at the beginning of April. Other sorts which I find most satisfactory are: Early Rivers', Early Lyons, Governor Wood, Empress Eugénie (one of the best), Nonnelle Royale, and Bigareau de Schreken. I ought to mention that for the purpose I employ two large vineys, and when the first by its growth begins to cause too much shade I transfer the pot trees into the next, and finally, when the fruit ripens, into a cool house. Just before the buds break into flower I fumigate with XL All Insecticide, as by doing so I find it invariably keeps them clean throughout the season. I have found by experience that it is not advisable to repot the trees every season; on the contrary, every two or three years is all that is necessary. The flowering period I prolong as much as possible by slightly shading, and I go over the flowers with a large camel's hair brush each day about noon. I am

always careful not to employ unnecessary fire-heat, and give air on every possible occasion. Of course when the season is over the trees are placed outside in a situation which is not too sunny, and the pots are simply covered with straw. When frost sets in we bring them inside again to be washed with a mixture of soft soap and sulphur just previous to starting them. Concerning Plums, I find them utterly devoid of all flavour when the slightest heat has been employed, and for that reason have long discarded their cultivation.—J. ROBERTS, *Villa Rothschild, Hoh Warte, Vienna.*

#### **Winter-flowering Pelargoniums.**

During the Chrysanthemum season, when, what with articles, notes, and reports, the gardening papers are full of the Chrysanthemum it is pleasant to turn from the somewhat slavish adulation bestowed on this autumn flower to some others even more beautiful, but less suited for exhibition and winning prizes. Very recently I called at Mrs. T. B. Haywood's garden, Woodhatch, Reigate, and found, as is the rule there in the winter, a good-sized span house full of zonal Pelargoniums in pots, some seventy to eighty plants flowering splendidly. To me these were far more interesting and beautiful than the two large houses filled with Chrysanthemums, although a very fine collection and capitally grown. But, whilst one sees these flowers everywhere, such a glorious show of colour as these Pelargoniums gave can be seen only here and there, and, so far as I know, nowhere better or more beautiful than at Woodhatch. Mr. Salter, the excellent gardener, disclaims any suggestion that the culture of these flowers needs special skill or is difficult. Certainly such is not the case. The plants now in bloom will have tops taken from them as cuttings at the end of February; they will be put into 5-inch pots, placed in a warm house or frame, be rooted, then later put into small pots singly. By June they will need shifting into 6-inch pots and be very firmly potted, then stood outdoors in the full sunshine on a hard floor, where the chief attention needed will be in keeping the plants watered, occasionally turning them round so that the sun may shine on all sides of them, keeping the points of the shoots and all flower-buds picked out, and, if aphis appears, giving the points of the shoots now and then a dusting with tobacco powder. During August and September weak manure water may be given. From the middle of the latter month pinching should cease, as the plants will then have become bushy, and must be allowed to form flower-buds. They may be housed about the end of September, and, if they have done well, will be in fine bloom early in November. A light, warm, well-ventilated house is best. Almost any variety will do well.—A. D.

**New fruits.**—It is not often at an ordinary meeting of the fruit committee of the Royal Horticultural Society that several awards are made to new fruits. On the 4th inst., however, the committee referred to had some interesting exhibits, and though these have been briefly noticed in THE GARDEN, it is well to give a few details concerning them. Grapes are so seldom given an award that when a new variety is staged it usually creates great interest. On this occasion I certainly think the new Imperial Black, shown by Mr. Goodacre, well deserved the award given. It is evidently an excellent late Grape, of large berry, vastly superior in quality to Gros Colman, and said to set its fruits freely. Mr. Goodacre did well to show it beside other varieties, and though as regards flavour it was not quite the equal of Black Morocco, the latter is such a bad grower that it cannot be classed among the useful late varieties. Its value as a market variety will doubtless soon be seen. Another meritorious exhibit, from Mr. Basham, of Bassaleg, Newport, Mon., was the new Apple Tamplin, and well worthy it was of the award of merit. At first sight it reminded one of American Mother, and probably the last-named may be related. Tamplin is a beautiful fruit, of conical shape, striped red, medium size, and of good quality. A new Damson or Bullace was also given an award of

merit. This was shown by Messrs. Veitch, and will, I think, be a valuable addition to the late stone fruits. It is called Langley Bullace, is enormously productive, and a very fine culinary fruit. The new Bullace is the result of a cross between the Farleigh Damson and the Orleans Plum: the fruits are round, yellow, and of first-rate quality when cooked. From the same firm came even a more interesting exhibit in the shape of a new Raspberry. This at first sight appears to be a distinct Raspberry, but the foliage shows its relationship to the Blackberry. Raspberry November Abundance is the result of crossing Raspberry Superlative with an American Blackberry, and is a very beautiful fruit, large, of good quality, an enormous cropper undoubtedly, and a splendid addition to our late fruits. A new Plum was staged by Mr. Messenger, Woolverstone, Ipswich, and, though not fortunate enough to get an award, was very good. It is a round, yellow fruit, very late, and of excellent quality.—G. WYTHES.

**A new winter Rhubarb** also received an award on the 4th inst. This is a very early variety, needs no forcing, merely protection, as it starts into growth very early; indeed, so early that unless protected it is cut down by autumn frosts. It came from two sources, from Messrs. Sutton and Sons, Reading, who called it the Sutton, and from Messrs. Veitch as Christmas Rhubarb. It is also similar to Topp's Winter Rhubarb, an American introduction that has been grown at the Royal Horticultural Society's Gardens, Chiswick. This new Rhubarb, though not large, is good, of a deep colour, and will be most valuable.—G. W.

The variety of Rhubarb, Topp's Winter, shown at the Drill Hall meeting on the 4th inst., is identical with Sutton's Christmas, also shown by the Reading firm at the same time, securing a similar award. The name Christmas Rhubarb has priority, as the variety was placed before the fruit committee under that name two years ago, and a plant of it was sent to Chiswick, where it has been grown also. The variety is of Australian origin, and here changes the usual Rhubarb season by resting in the summer and making its growth in the autumn and winter. The stems are of rich colour, and the quality is very good. To suit its growth to our seasons it is needful to invert tubs over the roots in the autumn, and, if hard weather sets in, to surround them with Fern or litter. So treated good Rhubarb may be had outdoors far more easily than it can be got in hot-houses or otherwise forced. It is folly to laugh at a Rhubarb that makes its growth in the winter; far better give it needful protection, and thus secure from it many pullings which should have considerable market value.—A. D.

**Growing Chrysanthemums for beauty of individual flowers.**—Soon it will be time, I believe, to prepare for propagating for the above purpose, I therefore anxiously request the help of THE GARDEN. I find myself confused amongst the various methods advocated by different writers. Some tell you to "Stop" at a certain height; others say "Never stop at all," but "Grow on the single stem." What is one to do? I do not aim at ever growing blooms fit for exhibition, for I have neither the ability nor the conveniences to enable me to do so. Nor do I wish to grow bush plants with many flowers or sprays: I aim at growing by the correct method for the beauty of individual flowers only (though inferior as regards size to show blooms), without regard to the shape of the plant. My houses are low in structure, so that I could not bloom plants exceeding 4½ feet high. Plants with one, two, or three stems with one good bloom at the end of the stem is what I aim at. Two of such plants I presume I could pot for flowering in one 9-inch or 10-inch pot. A list of twenty-four Japanese in whites, creams, and yellows, to flower from October to the end of December, I should also be grateful for.—J.A.P., *Eastbourne.*

**Honeysuckles.**—From Panton Hall, Wragby, Lincolnshire, Lady Mary Turner writes: "I read the account of the Honeysuckles in the

issue of the 15th inst., where L. sempervirens is mentioned as almost an exotic, and Cheshire mentioned as a point far north where it will grow. It may be of interest to state that there is a very fine specimen growing at Scotch Lodge, Edradour, about one mile above Pitlochry, on a southern aspect. It flowered particularly well this year in spite of the severe winter and spring. It seems to flower well all through August and September. Visitors generally seem struck with it, as the leaves are such a bright and beautiful green and the flowers catch the eye with their bright red colour and yellow stamens. I feel sure it gets no winter protection."

**Loss at the York Gala.**—Under the presidency of Alderman Sir C. Milward, a meeting of the council of the Grand Yorkshire Gala was held at Harker's Hotel recently. The balance-sheet showed that there was a loss on last June's gala of £634 8s. 4d., due to the inclement weather which prevailed at the time. This is the greatest loss which the society has ever sustained. The next business was the appointment of a secretary in succession to Mr. C. W. Simmons, who retired on the ground of pressure of other business, and Mr. Fred Arey, of 3, New Street, was elected to that position. In recognition of the services of Mr. Simmons during the fourteen years he was secretary, the council elected him a life member. Votes of thanks were accorded the ex-Lord Mayor, president for the past year, to Sir C. A. Milward, chairman of committee; Alderman Border, vice-chairman; Alderman Sir J. S. Rymer, treasurer; to Messrs. Harper (N.E.R.); and Messrs. Backhouse, Webb, and Sutton, for donations. It may be stated that notwithstanding the loss of the last gala the society have still a substantial balance in hand. With regard to next year's fixture, a committee was appointed to arrange

**Gardeners' Library at Edmonton.** In connexion with the Middlesex County Council School of Gardening, a garden library has been established at Pymmes Park, Edmonton. It already contains a good selection of the best books on gardening and botany, and is open for the benefit of gardeners on Tuesday and Thursday evenings, from 7.30 to 9.30, upon application to Mr. J. Weathers, County Instructor in Horticulture, Pymmes Park, Edmonton.

**Mr. Lewis Castle,** manager of the Duke of Bedford's experimental fruit farm, Woburn, has been awarded the prize offered last spring by the Worshipful Company of Fruiterers for the best essay on "Gathering, Preparing, and Marketing Plants and Vegetables, from the point of view of the Small Holder." The essay by Mr. Castle, who is to be congratulated upon his success, was, we believe, adjudged the best of eight considered by the judges.

**Canadian Fruit in London.**—In the window of the offices of the Canadian Pacific Railway, King William Street, are now being exhibited some very interesting specimens of fruit and vegetables from the fertile valley of the Thompson River, Kamloops, B.C., on the main line of the Canadian Pacific Railway. This valley is owned by the Canadian Real Properties, Limited, whose head offices are in London, and is being rapidly transformed from a barren waste into fruit farms, a striking testimony to the great fertility of the soil in this neighbourhood. This land has been lying idle for a number of years, but is now being rapidly reclaimed and cultivated.

**Keeping late Grapes.**—Late Grapes will require much care after the most unusual summer we have experienced. More particularly will this be so where the viney has to be used as a greenhouse as well. From what I have seen of late Grapes there is every possibility of their keeping badly, for the present season's wood is not well ripened and foliage is poor. While attention must be given to the individual bunches, berries being carefully taken out as they decay, there should also be close attention to the firing and ventilation. The foliage should be prevented from touching the glass. Cut away sub-laterals and remove detached leaves, for they hold much damp.—STEPHEN CASTLE.

**Lilium elegans.**—This Lily is commonly known as *L. thunbergianum*, and is one of the best of the early-flowering species. In the open garden *L. elegans* must have a sunny and well-drained spot, such, for instance, as on the edge of a large bank of Rhododendrons or in a bed of American shrubs. In such a place, with the welcome companionship of the fibrous roots of other plants, this Lily is quite at home. A coloured plate of *L. thunbergianum* Orange Queen was given in THE GARDEN for July 7, 1900.

### PALMS AND THEIR CULTURE.

The grace, beauty, stately grandeur, and valuable economic properties of many members of the various genera of the Natural Order Palmae, render these Monocotyledons unique in the plant world. As cultivated in our conservatories and Palm houses at home, but little idea can be had of the magnificent proportions to which they attain under more natural conditions. Although not having had the opportunity of seeing these noble plants in their native habitats, the splendid specimens noticeable in the Riviera have in a measure familiarised the writer—through a lengthened sojourn in that delightful part of France—with their unequalled value for the beautifying and adorning of the garden. There are, however, in this country a few glass structures spacious enough to admit of many tropical Palms attaining to a great size; such are the enormous warm conservatory at Chatsworth—the seat of the Duke of Devonshire—and the more familiar Palm house at Kew, in both of which Palms thrive remarkably well under the artificial tropical conditions there maintained. The number of species contained in the Palm family provides a great many different forms, ranging from specimens 100 feet high or more down to miniature plants whose highest leaves originate within a short distance of the ground. The leaves of members of the different genera also vary very much in size, as well as in form, and this variety of character renders them especially useful as decorative plants.

Not only for the adornment of our hot-houses, greenhouses, and dwelling rooms are Palms most useful, but by their presence the appearance of the sub-tropical garden during summer time is much enhanced, and one at least—*Trachycarpus excelsus* (*syn. Chamaerops excelsa*)—is sufficiently hardy to live out of doors altogether, and also thrive under the very trying conditions experienced in the course of a year in our changeable climate.

Neither is a tropical heat necessary to produce specimens of remarkable size and vigour, as a visit to the Temperate house at Kew will soon convince one. There may be seen in great luxuriance *Archontophoenix cunninghamiana* (*syn. Seaforthia elegans*), *Livistona australis*, *Trachycarpus excelsus*, and many others.

The economic properties of Palms are most important; many articles in daily use among civilised people are obtained from them, and natives of the countries where these plants are indigenous depend largely upon their products for a supply of food and many other necessities of life. To indicate the economic value and importance of Palms it will suffice to enumerate a few examples. The N. O. Palmae ranks next to that of Gramineæ, considered with regard to its economic properties.

The Sago of Commerce is obtained chiefly from *Metroxylon Sagu*, cultivated largely in and probably a native of Borneo, Sumatra, and the Moluccas. It is estimated that 4,000 tons of Sago are imported by this country annually. The fruit of *Cocos nucifera* (the Cocoanut Palm) is useful and valuable in several ways. The fibrous outer coating of the fruit, after being crushed and cleaned, is used for making brushes, and the coarser fibre provides material from which mats are made. An oil expressed from the kernels is employed in the manufacture of candles. The well-known Cocoanut fibre—so useful for horticultural purposes—consists of the broken particles which fall during

the process of cleaning the outer covering of the fruit. In the fruits of *Elaeis guineensis* (the Oil Palm) we have the chief source of the Palm Oil of commerce. The former are boiled in water, and the resulting oil on the surface is skimmed off. We import Palm Oil for use in the manufacture of soap and candles. That indispensable article in the garden—raffia—is furnished by a Palm from Madagascar, *Raphia Ruffia*. It is from the cuticle of the leaves that it is obtained; by the natives raffia is valued for making mats and articles of dress. The leaves when dry are used as books and for making various useful and ornamental articles. The Date Palm (*Phoenix dactylifera*), of which there are numerous varieties, produces fruits and leaves both of economic value. Baskets are made from the latter, and the petioles are sometimes used in this country as walking sticks.

The culture of Palms presents no special difficulties if ordinary care and attention are bestowed upon their management. Most of them require the heat of a stove-house properly to develop, while others from more temperate regions thrive best in a greenhouse. Only one species, *Chamaerops humilis*, is indigenous to South Europe. A few important conditions are necessary to the suc-

The propagation of Palms is chiefly carried on in tens of thousands by nurserymen, and it is as a rule more satisfactory to purchase small plants than to grow on the seedlings one's self. In a certain establishment, where Palms are raised from seed in large quantities, the following is the method adopted: Seeds are sown thickly in small shallow boxes, and the latter placed in a warm house. The period that elapses before germination takes place varies considerably, and depends chiefly upon the condition of the seeds when imported. Some will germinate in from one to two months, and others need a much longer time. A compost containing plenty of silver sand should be used for the seeds, and the drainage also must be ample and efficient, for, as the seeds sometimes remain dormant for a considerable time, if the above were not provided the soil would probably become sour. So soon as the seedlings are well rooted, instead of transferring them to larger pots they are planted out in a bed (having a slate base and containing about 6 inches of loam) with hot-water pipes immediately underneath. Here the seedling Palms are allowed to remain until 12 inches or 18 inches high, when they are lifted and potted into small pots for sale. If this latter work is carefully performed, and the plantlets are placed in a warm moist house for a short time until well established in their new quarters, the foliage will not appreciably suffer.

A. P. H.

LILIU ELEGANS.

cessful cultivation of Palms. It is most unwise to allow the soil in which they are growing to become dry during winter or the foliage will soon show signs of ill-health, and the beauty of the plant is then gone. Ample drainage and not too much root run are also important items. It is surprising how long a Palm will live and to what size it will attain when confined to a comparatively small pot or tub and left undisturbed, except for an occasional top-dressing. Such specimens are most necessary in those establishments where plant decorations are extensively carried out. A subdued light is rather beneficial than otherwise to their well being, as may be gathered from the fact that when grown in well shaded glass houses the leaves are of a much more pleasing dark green than if exposed to sunlight. Palms may be used over and over again for house decoration, and if carefully watered and cleaned their foliage will suffer to no appreciable extent. As a dry arid atmosphere is most hurtful to the foliage of these noble plants it becomes necessary to make provision for the maintenance of a proper amount of moisture in the air.

### ROUND ABOUT A GARDEN.

#### THE USE OF CLIMBERS.

WHAT English grounds and gardens lack most are climbing plants. We use creepers enough on our walls, it is true; and since bare walls are not beautiful, this is good. But often one sees among the wall creepers wretched plants that have to be nailed up at every 6 inches lest they should fall down, and often Roses that have been so trained and tortured from an old stem, that below they present to your view a lot of bare brown branches that wriggle all over the wall like centipedes, while you almost need a fire escape to reach any blossoms. Grow the same Rose as it should be grown, in a natural way upon a living tree, and the bare brown stems will always be out of sight, while the flowering branches will hang down in fringed festoons of loveliness which almost sweep the ground. I have seen the Maréchal Niel grown thus throwing out year by year new flowering branches 20 feet long, from which you might have gathered a barrowload of Roses and not have missed them from the tree. But that was not in England.

#### ENGLISH METHODS.

The English gardener seldom realises that climbing plants are intended to climb. Give him any plant with erect, self-supporting stem and he will know what to do with it; but give him a climber and he looks for a bare unclimbable wall to stick it against. Perhaps he will tie it to a straight stake or train it over a metal framework which gets heated by the sun and scorches every branch that touches it, or over a wooden trellis which becomes the home of thousands of earwigs that come out by night and eat the unlucky plant's tenderest leaves and flowers. When the climbers are allowed to ramble over a well-made pergola you see them to happier effect; but pergolas are not common in English gardens, and to make them well costs money, while, unless they skirt the margin of a garden, they obstruct the view.

#### PERGOLAS OUT OF PLACE.

And the worst fault of a pergola, unless it is constructed and tended with that infinity of art which exactly mimics Nature, is its obvious artificiality. In ninety-nine cases out of a

hundred the pergola gives a "tea garden" aspect to what might be fine grounds. You suspect a green summer house somewhere and a white-napkined waiter round the corner. In hotter countries, whence we have borrowed the pattern, the shady pergola is a luxury, almost a necessity; but we in England hardly realise the value to others of a shaded garden alley where they can plant their feet upon the smooth bare ground without fear of reptiles and loiter without risk of sunstroke.

#### ARTIFICIAL STRUCTURES.

In still hotter countries, where snakes abound to excess, and coolness can only be found in the open after sunset, a bare platform of masonry or concrete is raised above the ground level of the garden, and on this chairs are placed as the sun declines; but no one would think of trying to beautify an English garden with a structure like this.

Even in India, where the "chabutra" was once the focus of every "compound," the establishment of well-kept public gardens in every station, with broad drives and smooth spaces near the band-stand, where people can walk and sit in safety in the evening, has caused it to be regarded as an old-fashioned eyesore in a private garden. Although more ornamental, the pergola is open to the same objection as the chabutra, that it is an artificial structure which has no meaning or utility in a British garden.

#### HOW NOT TO DO IT.

As a stand for the display of choice climbing and rambling plants which cannot be accommodated elsewhere, the pergola has its use of course in a small town garden, where, too, it may veil an unsightly brick wall or form a protective screen against the prying eyes of neighbours; but such uses stand apart from gardening proper, and a pergola has no meaning where the ground can be cultivated for beauty alone. These climbing plants should be placed where they can climb. Take a boy who is fond of climbing and spread eagle him against a wall with strips of cloth and nails at every joint of every limb, stretch him over a wire railing, or tie him by waist and neck to a stout post—would he call that climbing? On the other hand, take a climbing plant and place it where it can get a good grip of the lower boughs of some suitable tree, and year by year you will be surprised by the new heights which it conquers and the wreathed wealth of blossom that it flings in season like a bride's veil over the tree which it is climbing.

#### THE CLIMBER AT HOME.

For the very character of the climbing plant, which makes it such a worry to the gardener who has to train it upon a wall or any fixed framework, is specially contrived to suit a free life among the branches of a growing tree. The old stems die because they would be hidden by the growth of the tree, and new flowering stems are thrown out which catch hold of the branches nearer to the sunlight, and from these in due season come a multitude of flowering shoots, just long enough to reach the very outside of the tree, which they cover with a wealth of bloom. When the blossoms have fallen and the climber on wall or pergola looks meagre and shabby, the green tree hides all defects until its leaves fall in autumn, and then the hard, bare lines of the branches in winter will be softened and clothed in part by the twining stems, bright fruit or evergreen leaves which the climbers, if you have chosen and placed them well, will retain until the spring in such natural shelter. E. K. R.

## TREES AND SHRUBS.

### JAPANESE MAPLES.

**A**CER JAPONICUM, *A. palmatum*, and their respective varieties, all of which are characterised by finely cut leaves, and the majority by highly coloured foliage at certain seasons of the year, are commonly known by the name of Japanese Maples. The above two species, however, are not the only *Acer*s that are natives of Japan, there being over a dozen others which hail from the "England of the East." There is a mistaken idea with many persons that the Japanese Maples are tender, and require shelter, &c., to keep them from being killed during the winter. This is totally different to our experience here, as they have been grown out of doors for the last twenty years and have never suffered to any great extent, though other so-called hardy shrubs have been badly injured by frost on more than one occasion.

There are several large plants of *A. palmatum* var. *sanguineum* growing here that must be, at the very least, thirty years of age, the largest measuring about 15 feet high by more than 20 feet in diameter, and these have never been injured by any winter they have passed through. Probably this district is the coldest, taking the year through, that can be found anywhere south of the Thames, and is also fully exposed to the east and north-east winds. If these plants are found hardy here then they should be the same in many other parts of the country, where the conditions are no less favourable, though I should not hesitate to recommend them for many colder situations. Plants, however, that are imported from Japan are not hardy in this country, though probably other causes besides frost may have something to do with their failure; but plants that are raised in England are as hardy as can be desired. It will occasionally be found that the points of the shoots are killed during the winter, but only when they have made a second growth in the autumn, and which has not had time to ripen before winter.

In the matter of soil to grow in these Maples are not at all particular. A light and rather poor soil is best, as this checks rank growth and helps to enhance the brilliant tints of the plants in spring and autumn. They also move well from the open ground, even if the plants have been allowed to stand for some years, and have not many fibrous roots attached.

Most of the Japanese Maples are forms of *A. palmatum*, the varieties of *A. japonicum* being *A. j. var. aureum*, with bright golden foliage; *A. j. var. crataegifolium*, which is a different plant to the species of that name, and having large deeply cut leaves, somewhat resembling those of *Crataegus tanacetifolia*, though on a larger scale; and *A. j. var. microphyllum*, which has small leaves much divided, and is of rather poor habit. The forms of *A. palmatum* are many and varied, and may be roughly classified into three divisions, viz., the *palmatum* group, where the leaves are five-lobed, resembling the type; the *septemlobum* group, the leaves of which are seven-lobed; and the *dissectum* group, where the leaves are many times cleft, the leaflets being narrow, and sometimes deeply serrated in addition. The exact number of these varieties is hard to define, and they are slowly being added to, as seedlings of many of them have been raised of late years, some of which are very handsome plants of free habit and good constitution. The distinctions between the sections cannot now be discussed, but a knowledge of the sections is useful to an understanding of the many variations found amongst these plants. The forms of the *palmatum* group are *A. p. var. crispum*, which has narrow, curled leaflets; *A. p. var. linearilobum*, the leaflets of which are long and narrow; *A. p. var. roseo-marginatum*, the leaves of which are variegated with pale yellow, edged with a rosy tint; and *A. p. var. sanguineum*, the best of all the Japanese Maples, the leaves being of a blood-red colour in spring and autumn, though turning duller in the summer. In the *septemlobum* group there is

*A. p. var. septemlobum*, which is a vigorous plant with little in the way of colour to recommend it; *A. p. var. septemlobum atropurpureum*, which has leaves of a bright purplish red colour; *A. p. var. septemlobum elegans (laciniatum)*, which has narrow leaflets and a pleasing feathery appearance, the spring and autumn colouring being of a pale red; and *A. p. var. septemlobum elegans purpureum*, which resembles the preceding except in the brighter purplish red colouring of its leaves. The *dissectum* group consists of smaller-growing plants with finely-cut leaves, which give them a delicate, Fern-like appearance, though they are quite as hardy as either of the other groups. The forms are *A. p. var. dissectum*, which has leaves of a light green colour, flushed with rose in the spring; *A. p. var. dissectum ornatum*, which has rosy tinted foliage in a young state, but turning green with age; and *A. p. var. dissectum rubrum (purpureum)*, with leaves of a deep red colour, rather duller than the other red-leaved forms of *A. palmatum*.

The spring and autumn colouring of these Maples renders them of great value to the planter, and in a favourable season there is a blaze of colour from some of them that is far superior to that of any other tree or shrub. The best for colour are *A. japonicum*, *A. j. var. crataegifolium*, *A. palmatum* var. *sanguineum*, and *A. p. var. septemlobum atropurpureum*. These should be planted in clumps of five or six against a background of green, and if the soil is a little poor and dry a wealth of colour will result that it would be difficult to surpass.

Bayshot, Surrey.

J. CLARK.

### CHRYSANTHEMUMS.

#### CHRYSANTHEMUMS AS STANDARDS.

**O**n account of its great vigour the Chrysanthemum is a plant which adapts itself to every whim of the cultivator. It has been exhibited in every imaginable form, as a low bush and in specimens of every form and height up to the enormous Japanese clusters with their innumerable little flowers. Sometimes it has also been exhibited as a standard. For some years past the public has appeared to take interest in this kind of exhibition, and especially so when the blossomed heads are of clear colour and well outlined. In our opinion, in order to obtain the best effect with this form of plant—the size of the flower matters but little—the great thing is that the head should be furnished with flowers of brilliant colour. The height of the stem is only of importance so far as the use to be made of the plant is concerned. The essential thing is that the flowers should stand out well amidst a group of plants.

For the benefit of those who may be tempted to try the cultivation of this plant we will briefly indicate the work necessary to obtain fine specimens. It may easily be supposed that the time required to bring this plant to perfection is comparatively long. The height of the stem must first be attained, next the head must be formed, and finally the flowers must be perfected. These different operations take from ten to thirteen months. Cuttings should therefore be formed by taking well-grown suckers in December. These should be made to take root, and be grown either under a forcing frame upon a hot-bed or near the glass in a good, moderately warm greenhouse. They should be successively repotted in such a way that their growth is not checked, and so that the height desired for the stem may be reached in April or May at the latest. It is very important that the first branching should be formed naturally. The ramification thus resulting is much stronger than that secured by pinching off the head. There are two easy ways of obtaining this at a greater or less height—first, if you desire semi-standards choose naturally dwarf varieties; second, give the plants more or less air. Under

glass it will continue to increase in height; in the open air, on the contrary, the growth will be thicker, and the plant will branch lower. The branches thus obtained should be pinched off, leaving a length of three or four leaves. The succeeding branches should be treated in the same manner, and this should be repeated as many times as possible and as is necessary to obtain the desired head, but always on this condition—that the last pinching is done before the end of July. A good way to make possible these repeated pinchings in the rather limited time is to put the plants in old hot-beds of which the materials have well rotted. Under these conditions the plants make a strong and rapid growth, which enables them to bear the pinchings necessary in order to obtain a head of large dimensions. They should be taken up during the first fortnight in August and be well watered during the period of re-rooting. They should then be provided with good stakes to support the stem, and the head should be surrounded with a few rounds of iron wire in order that the branches

runs a passage in an admirable leader on the flower of the moment in THE GARDEN of the 8th inst. Why cannot we have Garden Chrysanthemums may not be easy to answer satisfactorily, from a certain standpoint at any rate. On the other hand, it should prove a comparatively easy matter to obtain a section of these flowers that would suit the gardener exactly, and indeed far better than any others. It is possible, however, that the raisers of Chrysanthemums themselves are not so keen on the subject of Garden Chrysanthemums as they are for the "big bloom" craze. Therefore we must look to some enthusiastic hardy plant amateur to create a set of varieties that shall not merely be Garden Chrysanthemums for a time, but merit the term "garden" in its fullest and broadest sense—that is to say, the present decorative sorts that create so brave a display in the open in the early autumn months would in no sense supply the want, as at the very outset these are not hardy kinds, and hardiness must be a *sine qua non*.

To this end, therefore, we must look to the more

flowering sort, which I named Golden Sheaf. The plant has received no protection, and though a few have perished I could have raised hundreds by division alone had I required them. Perhaps its great fault is in the lateness of flowering, for the variety in no season has been well in flower before November 18. This year it will be later. In the time of flowering, Golden Sheaf shows the influence of Admiral Symonds, while its more double flowers, I suppose, came from the yellow Desgrange side. The plant is nearly 3 feet high, is never staked, and has not been protected in any way since it first flowered as a seedling. In habit it is vigorous and intermediate between the parents, while the sheaves of showy yellow flowers that are good for nothing but the garden suggested the name Golden Sheaf. And it is among these possibly worthless kinds for other purposes that we may find sufficient material to start a set of Garden Chrysanthemums. These should be characterised by hardiness, by free growth and easily-opening flowers, and by coming with and outlasting the Michaelmas Daisies. The amateur who could see his way to creating such a set, or indeed anyone, would be doing good service.

E. JENKINS.

## FLOWER GARDEN.

### HYACINTHUS CANDICANS.

**P**OPULARLY known as the Cape Hyacinth, this noble late July flowering bulbous plant should be planted in a bold group, as shown in the accompanying illustration, to get the best effect from the broad light green leaves and tall spikes. Like many strong growing bulbous plants, the Cape Hyacinth is very charming when planted amongst shrubs in woodland or border. Its tall stems are less exposed, and they rise gracefully from the undergrowth, as it were, of other plants. The photograph from which our illustration was made was kindly sent to us by a correspondent, whose address, unfortunately, we have mislaid. Perhaps the person to whom we are indebted for the opportunity of figuring this valuable garden plant will be so good as to send fuller particulars.

### PINK ASTERS.

HAVING both Perry's Pink and Perry's Favourite I can quite concur in the praises of these two pretty Michaelmas Daisies—to use the old name that has pleasant associations, and is too good to let slip away. Although the rather small but very profusely borne flowers of Perry's Pink are quite pure and very lovely in colour by candlelight, and of a very passably true pink by day, I should not call Perry's Favourite, which is an Amellus, and quite different, of course, in habit to Perry's Pink, more than a pink-lilac in colour. It seems to me that it is a great pity florists and growers will persist in misapplying colour names as many do. In nearly all catalogues numbers of lilac and lavender flowers, perennial Aster included, are described as rosy pink which are not of that colour in the very least; also, flowers that are violet, as some of the Iris Kampferi, are offered—most misleading—as crimson, and lilac ones as rosy pink. Where on earth does the pink in these come in? The word is a good expressive one, surely suggesting to everyone the colour of a La France or Caroline Testout Rose, and why should it be used to describe mauve or lilac?

However, to return to the subject of this note. It is, I suppose, much more of an achievement to get anything approaching pink in an Amellus

A GROUP OF HYACINTHUS (GALTONIA) CANDICANS IN THE BORDER.

may be properly trained, and that the head may obtain a handsome well rounded form. There is nothing more to be done except to bestow the usual care, such as watering with liquid manure, removing superfluous buds, freeing from insects with sulphur, in a word, doing everything which can be done to ensure luxuriant growth. It only remains to give the names of a few varieties which adapt themselves to this training. They are the following: Baronne de Vinols, the Laforgue Chrysanthemum, Etoile de Lyon, Etoile de feu, Marie Calvat, Myrto, M. E. Stradfort, Paris 1900, Phœbus, President F. Sahut, Princesse de Brancovan, Pride of Madfort, Pygmalion, Rêverie, Soleil d'Octobre, Souvenir de Pont d'Avignon, Vicomte de la Tour, William Tricker, Mme. Gustave Henri, President Dotailly, Thérèse Mazier, Féerie, Braise, Banquise, Marie-Thérèse Bergman, Mme. Charles Kratz, Emile Deseine, as well as any vigorous variety whose branching is short and strong.

A. NONIN in *Le Jardin*.

diminutive flowering kinds—that is, those of the old Pompon class more particularly. The thing to aim at is a class or group sufficiently hardy and equally perennial in their character to admit, as most perennials do, of spring division and replanting when this becomes necessary. To obtain such a set should not be an insurmountable task, provided a beginning was made with those kinds most nearly related to the original varieties of Chrysanthemum indicum.

Of these there were several varieties grown nearly thirty years ago, and the principle was that of leaving the plants quite unprotected. Doubtless from among the great wealth of material now grown of ordinary kinds, some few could be found sufficiently hardy for the purpose of trial, though the better way would be to start afresh on the lines indicated.

In the large-flowered or decorative classes the well-known Source d'Or may prove a good working variety, at least as a pollen parent, while the semi-double Admiral Symonds would constitute a free grower also, and one fairly hardy. From this last-named sort, crossing with yellow Mme. Desgrange some five or six years ago I obtained one capital hardy free-

### GARDEN CHRYSANTHEMUMS.

"WHY should we not be able to speak of Garden Chrysanthemums as we do of Garden Roses?" So

MESEMBRYANTHEMUM ACINACIFORME AT KINGSWEAR, S. DEVON.  
(Flowers deep rose, 4 inches across.)

variety than in the *Nova Angliae* section, still Ryecroft Pink is a real pink. It apparently belongs to the *N. Angliae*, though it may be a hybrid, but I have not seen the raiser's description. The colour is pure, rich, and bright, the foliage a light, fresh-looking green, which, by the way, is also the case with Perry's Favourite. Ryecroft Pink seems to be a good grower, and my plant, though the cold spring and two removals worried it very much, is blooming well. The flowers are the size of a shilling or a little larger, and have the finely fimbriated petals characteristic of the *N. A.* section; it is 3 feet high. Ryecroft Purple, close by, is an exact match in size of flower, height, and habit, but the blooms are the exact colour of an amethyst stone. Neither is aniline nor crude in tone.

Bath.

M. L. W.

#### NOTES FROM WORCESTER-SHIRE.

ONE of the most charming seats in this county is Shelsley Walsh House, the residence of Montague Taylor, Esq. Situated at the foot of a well-wooded range of hills, which slope down to the river Teme, the house, which dates from the fifteenth century and was originally moated, commands an exquisite view of the surrounding country. The Teme Valley has long been noted for its magnificent scenery, and its soil, which is a rich fertile loam, is mainly devoted to the culture of fruit and Hops. Mr. Taylor's plantations of Apples and Currants occupy

masses of the dwarf Rudbeckia Newmanni. Very beautiful, too, were the recently made beds of Tea and H.T. Roses of one variety. For wealth of bloom Mlle. Yvonne Gravier, to which attention has previously been called in THE GARDEN (page 201), was quite the best. Other varieties most remarked were Grüss an Teplitz (fine for pegging down), G. Nabonnand, Mme. Jules Groléz, and Bourbon Souvenir de Malmaison. The new Tea Rose, Mme. Berkeley, was also noticed, and seemed very promising. It is a robust grower, semi-double, with large salmon-white petals, and obtained an award of merit from the Royal Horticultural Society last year. Anyone who is interested in hardy plants can always enjoy themselves at

MESSRS. RICHARD SMITH AND CO.'S NURSERIES. The department is under the control of Mr. W. Horsman, whose knowledge of hardy plants is very considerable. When I paid my autumn visit the borders were gay with many of the yellow-flowered Composites, Starworts, Solidagos, Colchicums, Kniphofias, Monbretias, &c. It was quite a revelation to see *Helianthus tomentosus* (*mollis*) completely covered with myriads of its neat black-centred blossoms. I consider it is *facile princeps* of the Sunflowers, especially for house decoration. Then came the Asters, and one could not help admiring that beautiful species *Porteri*, as yet comparatively unknown. It is a first-rate plant of excellent habit, and not at all straggling. On the whole it bears some resemblance to *A. ericoides*, grows barely 2 feet in height, and starts to flower

many acres, and are models of good culture: but owing to a plague of rabbits bush Apples have had to be abandoned in favour of standards and half-standards. The garden at Shelsley House is sheltered by steep well-wooded hills from the north and east, and from one of these rises a small stream which flows through the grounds and feeds a pool. This pool was constructed in place of the moat which has now been done away with. Trees and shrubs luxuriate, and form pleasing pictures on the steep sloping ground. Many visitors come to see the enormous specimen of the Himalayan *Picea morinda*, said to be the finest of its kind in England. Mr. Taylor tells me that it was raised from seed sent to a previous owner of the estate. Unfortunately, this imposing tree is now past its best, although still very handsome. Visiting

MADRESFIELD COURT GARDENS at the end of September, I found that in spite of this inclement season Mr. Crump had some very excellent crops of hardy fruit. To mention but a few kinds, Pears Doyenné du Comice and Marguerite Marillat were superb against a wall, while Apples Newton Wonder, Royal Jubilee, Lane's Prince Albert, May Queen, and Pott's Seedling were exceptionally good. Those who have not yet given May Queen a trial should most certainly do so. It is a brightly-coloured dessert Apple introduced by Mr. Crump, below medium size, of good flavour, and keeps till April or May. On the stiff land at Madresfield it crops well, and is also doing well on the light sandy soil in my garden. Bedding out is not much in vogue at Madresfield, but I noticed some very beautiful combinations. I was particularly delighted with some large beds of the bright purple *Verbena venosa*, planted in contrast to some fine

early in September, covering itself with small white blossoms with yellow centres. According to the "Kew Hand List" its habitat is Colorado. Of the Colchicums, *speciosum* was easily the finest species in bloom at the time of my visit. Its flowers almost resemble a Tulip, are of a rich crimson-purple, and measure 7 inches or 8 inches in length. Two other smaller kinds were also very bright, i.e., *arenarium*, a Hungarian species, with pale rose-purple blossoms, the other being *umbrosum*, a rich violet-purple in colour. Many other good and rare plants were in bloom, but space prevents my making mention of them here.

Worcestershire.

ARTHUR R. GOODWIN.

#### NOTES ON HARDY PLANTS

##### MESEMBRYANTHEMUMS.

**M**ESEMBRYANTHEMUMS are not everybody's flowers, and the fact that there are, indeed, few localities in the British Isles where they can be successfully cultivated doubtless accounts for the paucity of the notes that appear in the horticultural press on this brilliant race. Where they succeed there are few subjects that equal them for effect, while the various species prolong the blooming season for many months. In mild winters solitary blossoms may be seen on such species as *M. aurantiacum* or *M. roseum* as early as February, and belated flowers are often expanded as late as November. These dates do not, however, fall within the ordinary blooming period, which may be taken as extending from the middle of March to the end of August. A light, porous soil and the proximity of the sea appear to be indispensable to the satisfactory growth and flowering of Mesembryanthemums, for I have never met with a good collection inland, and in heavy soil, even within half a mile of the sea, the plants, while growing, have refused to flower. The best collection is undoubtedly that contained in the gardens of Tresco Abbey, Isles of Scilly, where 120 species are grown. Here the porous soil consists of peat and disintegrated granite, and the sea is close at hand.

In the rock garden at Abbotsbury Castle, Dorsetshire, a very large number of species are to be seen in the most vigorous health. This rock garden is formed just at the top of the Chesil Beach, where in westerly gales the flying drift must be blown into the unprotected garden, but the Mesembryanthemums evidently revel in the situation. In the Isle of Wight these plants flourish, as they also do at Kingswear on a steep and sunny slope at the mouth of the river Dart. The climate in the four localities named being mild, it may be inferred that warmth is imperative for Mesembryanthemums, but that this is not essential where other conditions are favourable may be gathered from the fact that *M. roseum* has lived out through the winter unprotected as far north as Scarborough, where it has flowered abundantly in the summer.

A good deal of uncertainty exists in the nomenclature of Mesembryanthemums, the descriptions of some of the species in the horticultural dictionaries being so dissimilar to the plants flowering under the same names in the best collections that one naturally writes with diffidence on the subject. Perhaps the best-known species is *M. edule* (the thick-leaved Hottentot Fig), which bears large yellow flowers. Its blossoms are said by a certain horticultural dictionary to be pink. From its

fruit jam is extensively made in Cape Colony. It was this trailing plant that M. Jules Verne, in a thrilling romance of African adventure, makes three horsemen shelter under during a tropical thunderstorm, complete protection being afforded them by its *umbrageous branches*. It grows rampantly in the Scillies and along the southern coasts of Devon and Cornwall, and at Newlyn Harbour spreads a veil of foliage over a wall lapped at the foot by the salt water. *M. acinaciforme* is a far handsomer species, with the same thick leafage as *M. edule*, but bearing large blossoms of deep rose colour 4 inches in diameter. Of the smaller flowered species *M. aménatum* and *M. tenuifolium* are the two most brilliant that I am acquainted with, the blossoms being of a vivid crimson-scarlet, absolutely dazzling in the sunlight. The former, which I myself brought from the Cape, is perhaps a trifle less glowing than the latter, but there is little difference. The colours of these two species, given in gardening dictionaries, do not bear the faintest resemblance to the hues displayed by plants in full bloom at Abbotsbury. *M. coccineum* is another species bearing bright red flowers. *M. caulescens* has deep red flowers about half the size of those of the last-named. *M. aurantiacum* bears flowers of a deep orange tint, and is one of the earliest to bloom. *M. aureum* has also orange-yellow blossoms. Other attractive species are *M. lepidum* (white), *M. lineolatum* (pink), *M. productum* (rosy purple), given in the dictionaries as pale pink), *M. roseum* (bright rose), and *M. rostratum* (yellow). *M. tigrinum* is an interesting plant, chiefly remarkable for its foliage, the hollowed leaves being edged with curved spines, which give the idea of a tiger's expanded jaws.

In the south-west Mesembryanthemums are rarely killed by the winter, though totally unprotected. Old plants, however, sometimes become bare and ragged, and for this reason it is advisable to raise cuttings, which strike readily in the autumn, to take the places of old specimens that have been rendered unsightly by age. Mesembryanthemums are difficult to obtain through the trade, catalogue after catalogue making no mention of the name. Any firm enterprising enough to take an acre of land on the coast of southern Cornwall would have no difficulty in getting together and growing unprotected in the open a representative collection, from which the wants of such amateurs as are able successfully to grow the genus might be supplied. At present it is only through the generosity of owners of private collections that the different species can be obtained.

S. W. FITZHERBERT.

Kingswear, South Devon.

#### A NOTE FROM ARBIGLAND, N.B.

IN the South of Scotland there are several gardens which are highly favoured as regards climate and position. One of these is that of Arbigland, the property of Colonel C. E. Blackett, a place which has for years been steadily growing in interest to garden lovers. Favoured as Arbigland is, it is seldom that there are so many half-hardy flowers in bloom in the garden there on the 1st of November as this season. Not a Dahlia had been cut down by frost; Tropaeolums and many other tender things were in bloom on that day, and the garden was wonderfully bright for the time of year. At such a late date one could not expect to see everything at its best, for Begonias were almost over, though still in flower. Hollyhocks were nearly past, too, although they have been unusually good and almost free from disease. There were thousands of Dahlia blooms, the singles in particular being remarkably good for the season. One had also an opportunity of

seeing the Cactus Dahlias and comparing their qualities for garden decoration. The three best were Starfish, Mrs. J. J. Crowe, and Red Rover, the first being undoubtedly the best; it was almost covered with flowers. Green's White had plenty of flowers, and was good early in the season, though latterly, on account of the want of sun, it had lost much of its purity of colouring.

Half-hardy annuals were full of bloom, while early Chrysanthemums were giving plenty of flowers. The later varieties are just opening, but give promise of fine blooms. There was also a good show of Pentstemons, the produce of two different strains of seed, and both showing the great advance made in these flowers within recent years. A fine effect was made by pillars of *Tropaeolum aduncum* (*peregrinum*), the Canary Creeper.

Roses have been largely added to at Arbigland in recent years, and one had an opportunity of noting which were the best for the locality for the time of year. Undoubtedly the freest flowerer, apart from the Chinas, is *Rêve d'Or*, which was laden with capital flowers. Mme. Isaac Periere has been good this season also, but may not be so fine in a warm season as in this cool one.

The autumn tints in the grounds were beautiful, and one unnamed Maple, which had been sent from Canada, was so fine that an effort is being made to secure some others of the same species, its identification being in progress.

The Bamboos in the Japanese garden formed last autumn are doing well, and there is no doubt that Arbigland is well suited for these graceful and attractive plants. It may be mentioned as showing the mildness of the place that old roots of *Cactus Dahlia Juarezii* have been left out in the open ground for several years unprotected without injury. The same mild climate accounts for the splendid Portugal Laurel, the finest, I believe, in the South of Scotland.

It is situated near the garden entrance, and has attained to great dimensions, although it has had to be cut in from time to time to prevent its encroachment on the pathway.

S. ARNOTT.

#### PHYSOSTEGIA VIRGINIANA ALBA.

I NOTE on page 204 of THE GARDEN that Mr. Mallett speaks of this variety as "rare," further observing that it "gives promise of becoming quite as strong and free as the type." I can assure Mr. Mallett it is all this, and has been so for many years now. This plant is anything but rare, indeed it was obtainable at quite a cheap rate a score of years ago, can be had in quantity now if required, and is quite as cheap as many hardy things. Indeed, there is no reason why any plant that yields seeds freely should be scarce. It may also be increased by division as well as by cuttings if required. The plant may be put to a freer use than is now the case perhaps, and particularly for grouping is it to be recommended. It is not happy in hot sandy soils or in those of clay generally, but in

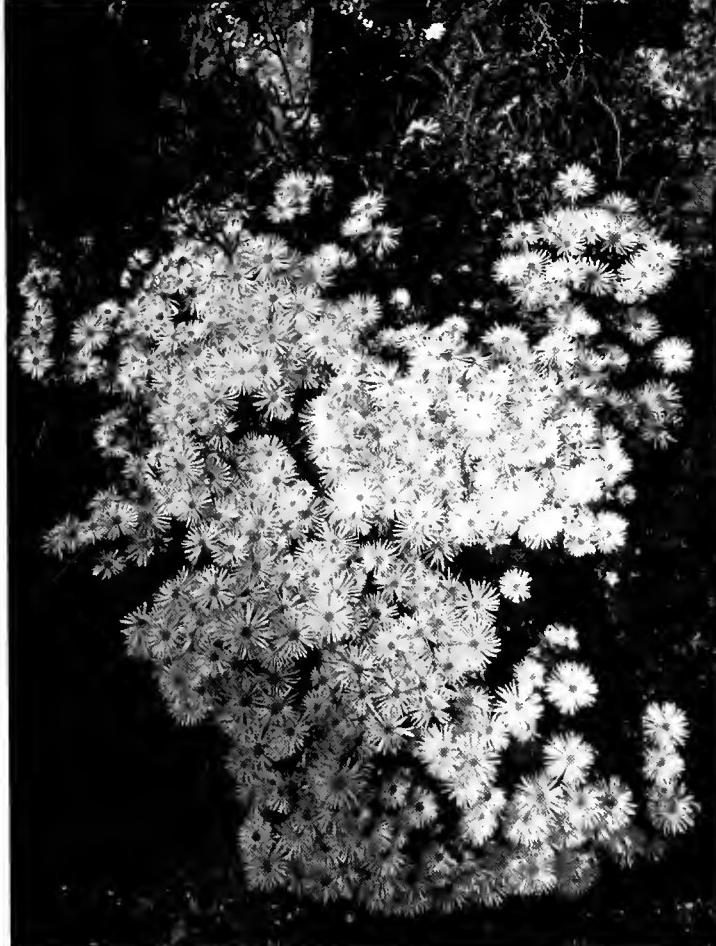

the intermediate class of loamy soils will grow and flower freely. In this locality in light loamy soil, heavily dressed with cow manure, the type and the above always grow apace.

Hampton Hill.

E. JENKINS.

#### CIMICIFUGA JAPONICA AND C. SIMPLEX.

MR. WOLLEY-DOD, in writing of the former plant in THE GARDEN, rightly conjectures that confusion exists in respect to the nomenclature of these things. There is, however, a wide difference between *C. fetida*, which has been flowering in the herb ground at Kew this season, and which Mr. Wolley-Dod cites as equivalent to *C. simplex*. *C. fetida* as grown at Kew is nearly 7 feet high, of rather sparse habit, and with a semi-arching inflorescence of white flowers that present an aspect quite distinct as compared to the erect cylindrical and very pure white of the flowers of the plant long known as *C. japonica*. This latter is the plant that at the Drill Hall recently was said to be *C. simplex*, and it is of a more bushy rounded habit at 2 feet from the ground, as well as possessing the smallest and neatest leafage of any kind. I also remember the plant under the name *Pityrospurma acerinum*, but had overlooked it. The recently certified plant has been labelled *C. japonica* at Kew until recently, but I believe a doubt now exists as to the accuracy of the name, and the fruiting of the species was then awaited. I have no recollection of the fruit of this species, though I have known the plant for some years. If, however, the certified plant should prove to be *C. simplex*, the next question is, What is *C. japonica*? I have not had an opportunity of comparing herbarium specimens, but doubtless the matter could be quickly disposed of in this way.

MESEMBRYANTHEMUM ROSEUM IN SOUTH DEVON.

With regard to the actual "award of merit" at the recent meeting, this was granted to the plant upon its merits, as is frequently the case, and not as a novelty. It is, however, difficult to see what good is done in a case where the plant has been many years before the public.

E. JENKINS.

### IN A CORNISH GARDEN.

THOSE who are acquainted with the quiet reaches of the Tamar, that charming river which separates the counties of Devon and Cornwall, know it to be a surpassingly beautiful region of England, where Nature is in one of her most luxuriant moods, as we in northern climes are accustomed to judge of natural luxuriance. A glance at our illustration will convince the reader that the

gardens of Cotehele House are no less beautiful than the surrounding country. There is a picturesqueness and freedom of character apparent, giving a true breath of Nature, in the planting and surroundings of this delightful Cornish abode, that make a charming contrast to the stately and formal gardens that are found in many English counties.

light golden discs from out the Elm trees, Beech leaves of saffron-yellow ribbed with brown, Maple and Chestnut leaves with yellow spots and rims, and jagged Oak leaves tough and tawny. Every notched or pointed leaf, a short-lived butterfly, floats downwards with a movement of its own; no two alike, and each with its own beauty. How, in the glow of sunlight, the light-winged leaflets pause and poise and hover, or glittering turn upon their sides like swimmers. This is their moment of perfect freedom, the supremest of their lives—long looked-for, yet startling when it comes, like death or the first frost. To us it may seem brief, but who can measure time? It may be to them as the time in dreams.

Deeper and deeper grow the leaf-drifts, and ever more thickly strewn the pathway through the woods. Why do the Poplars shiver so, and why are their clinging leaves so timid of the fall? Tremblingly they watch the roadside tumbrils, bearing away their heaped-up comrades to some unknown fate. They have lived their fair green lives against the sky, bathing in dew and sunlight; it is all they know. What of them now? Is this to be the end, to lie apart from their dear boughs, severed from the frost-stricken branches, to die on earth, these creatures that had lived in air?

But the fallen leaves are happy. In their death there is no sting. A crisp and pleasant cheerfulness pervades them as they look up at us instead of down. Happy were their useful lives, and cheerfully they let them go. Even as they are trodden under foot a poignant, delicious fragrance rises responsive to our mood. What joy to childish feet, that revel in the year's dead leaves, kicking them aside to hunt the Acorn's fairy cup, the wrinkled Walnut, the emerald Almond-sheath, the red-brown polished Chestnut, breaking from its bed of cream. Even to the tired feet the dead leaves bring refreshment. There is no lacerating of heart-strings, as when the young die, but a sense of satisfied fulfilment, a feeling of work done, rest won, more pleasing to many of us than the stir and promise of the spring. The setting sun grows brighter as it shines through wet transparent leaves of Lime and Beech; but one more night of frost, one day of storm, and every small frail handmaid of the trees will drop.

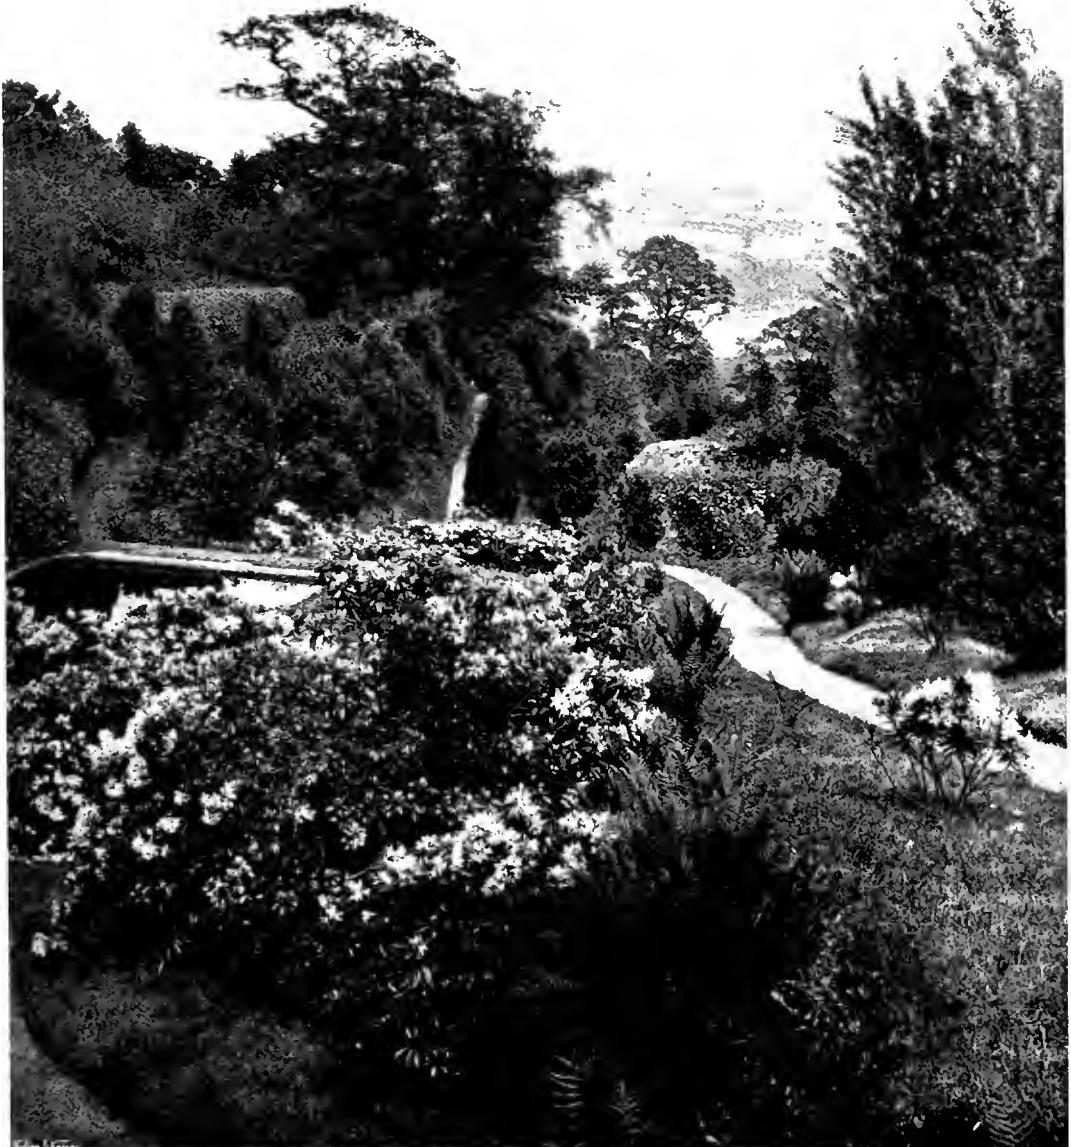

"The last red leaf is whirled away." Gone, ere we could possess them, the magic of the yellow noon, the first crisp frou-frou of the leaves. No remnant now upon the barren spires save one belated lingerer high up on the Plane tree, who shakes his farewells with a fingerless glove.

Whither have they vanished, those varying myriads that in spring had made the woods so fair? On some light flutterers the winds have seized; there are fine frolickings upon the hill and up and down the lane, where rich damp ruts and cart tracks are strewn with golden guineas. To the kitten on the lawn the scattered Beech and

### THE DEATH OF THE LEAVES.

"Earth watches while her little children die."

It is what Emerson calls "a yellow afternoon." We walk out in the pale gold sunshine and the air is full of leaves; not wind-blown, there is not a breath, but silently the leaves come fluttering down, how soft, how slow,

IN THE GARDENS AT COTEHELE, CORNWALL.

Chestnut burrs are playmates. Willow leaves are drawn down out of sight to feed strange creatures below ground. Rose leaves, tender hearted, are making robin redbreast palls to cover the dead flowers; the stoutly-fibred will weave lace-leaves—miracles of fineness, to be found at Christmas time in humid corners or near the brook. But some will know the happiest fate of all—it is to lie in the quiet sanctuaries of the woods, where forest trees may stand in them knee deep. Silent are the rhapsodies of red and gold, the symphonies of bronze and russet, sheltered by the patient brotherhood of boughs; the soft damp leaves, more sombre every day, sink slowly to their uniform brown rest. Deep is their content. Faithful to each other in life, in death the leaves and trees are not divided.

F. A. B.

## AN ARTIST'S NOTE-BOOK.

### ROSE MILDRED GRANT (HYBRID TEA).

**N**O one who saw the fine bloom of this variety that obtained the silver medal at the Temple show will readily forget it. Magnificent in its high tapering centre, wonderful in petal, the outer ones measuring fully 4 inches deep, and lovely in its delicate blush-white colouring, this Rose certainly stood out as evincing the greatest achievement of the hybridist's art. I do not like to find fault with such a Rose, but to me the tint of pink seemed wanting a little in brightness. This, however, is a small point, and will not in the least detract from its great merits. One thought on admiring this bloom what would such an one be with the colouring of Victor Hugo or Ma Capucine? Are these fancies too extravagant or shall we obtain them in the near future? I am optimistic enough to believe that we shall. P.

## THE INDOOR GARDEN.

### LACHENALIAS FOR BASKETS.

**A**MONGST the large number of early-flowering bulbs none excel the Lachenalias for providing a show of flowers in early spring. Although they may be very successfully cultivated in pots, it is not of that method I wish to treat in this article, but rather to bring to the amateur's notice their general usefulness as material for planting in hanging baskets in order to embellish the conservatory or greenhouse. What are their general characteristics? They are these: Firstly, the Lachenalias are the easiest of bulbs to grow; secondly, they take up very little room when grown in the way suggested; thirdly, they increase rapidly, and seldom fail to produce a good crop of flowers, accompanied by a profusion of foliage ornamental in itself. These three points then will justify my remarks.

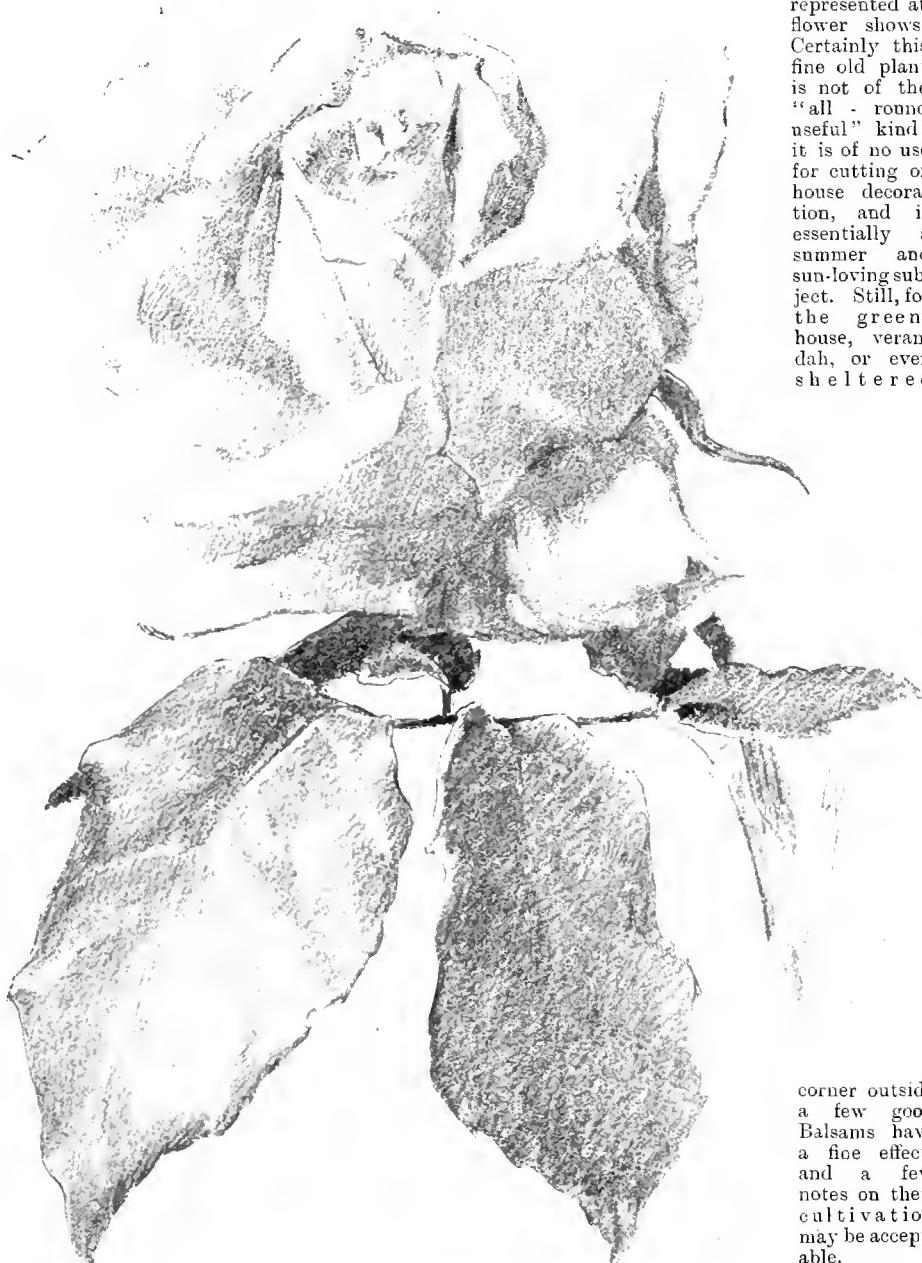

The best season for potting the Lachenalias is the latter end of August, therefore by this time the bulbs ought to be well advanced in growth. It is advisable to start them in pots, as in this way they will be ready for baskets which may have been out of doors during the summer months, or if baskets can be spared the bulbs may be planted in them and placed in a suitable situation to start.

Lachenalias require a rich compost, and when they have this the growth is astonishing. A suitable compost may consist of good fibrous loam one part, leaf-mould one part, sand and well-

decayed cow manure making up the remainder. Well "crock" some 2-inch pots and place two or three bulbs in each, just covering them with fine soil. Give the pots a good watering and place them in a cool frame, giving them no more water until the growth is well advanced. As soon as they are about 3 inches high they may be turned out of the pots and replanted in baskets, using the same rich compost as before and placing plants from seven or eight pots in each basket according to their dimensions. When they are well rooted

### THE BALSAM.

"A WELL-GROWN Balsam is a bonnie plant, but a bad one is an ugly weed," an old master of mine used to say, and perhaps there are few plants which show the effects of good or bad treatment so plainly. Considering their easy culture, provided a suitable place is to be had, and the great beauty of a good specimen, I think it must be the want of the little extra attention which makes them so comparatively rare in our greenhouses and poorly represented at flower shows. Certainly this fine old plant is not of the "all-round useful" kind; it is of no use for cutting or house decoration, and is essentially a summer and sun-loving subject. Still, for the greenhouse, verandah, or even sheltered

HYBRID TEA ROSE MILDRED GRANT. (From a drawing by H. G. Moon.)

there is no fear of over-watering them, except when the bulbs have finished flowering, water being then gradually withheld until the tops have died down. It is advisable when repotting to use only the finest bulbs, the smaller sizes being placed in a suitable medium to grow and make flowering bulbs for the following year. These three Lachenalias—*L. pendula*, *L. Nelsoni*, and *L. tricolor*—are suitable for hanging baskets, but the first-named is preferable. J. DENMAN.  
The Laurels, Cains Cross, Stroud.

corner outside a few good Balsams have a fine effect, and a few notes on their cultivation may be acceptable.

I may say that the very best place to

grow them is in a light frame placed on a mild hotbed where they can be kept close to the glass. Seeds must be sown in spring; towards the end of April is a good time, but they can be sown a week or two sooner or later as required. Sow in pans or boxes of light soil, and plunge in a heat of about 75°. A good compost consists of loam (three parts), leaf-mould and well-rotted manure (one part each), sand as seems desirable, and perhaps a little bone-meal. The plant is a gross feeder, and nothing in the shape of artificial manure, soot, &c., comes wrong

if used with reasonable moderation. When the young plants are well up they need potting into 2½-inch pots. No crocks are required till the last shift, the rougher part of the compost being sufficient. Pot deeply and moderately firm, return to the hot-bed, and water carefully with water about the temperature of the bed. This is important in the earlier stages of the plant's growth, and desirable all along. After potting, a little shading may be necessary for a day or two, but the less the better. It is as well to have a few plants more than will be ultimately needed to allow of a weakly one or two being discarded. The next move will be into about 5-inch pots, although this will depend on the size of their flowering pots. A good plant can be grown in a 7-inch or even a 6-inch pot, but they can be grown to fill pots 9 inches or even 11 inches in diameter.

An excellent plan is to leave about one-third of the pot to be filled up by degrees with rich compost as the plant requires it. Some pinch their plants several times, others prefer them grown naturally. There are those who say they ought to be carefully staked, others maintain that staking spoils them. While I believe that good plants may be had in all the different ways, my own preference is for unpinched plants, not exactly unstaked, but staked as little as may be. If large plants are wanted it is as well to pick off the flower-buds for a time as they appear, stopping this two or three weeks before the display is desired. Air should be afforded in increasing quantities as the season advances, so that by flowering time they need little or no protection if the weather is good. Insects seldom, in fact never, trouble them if the accommodation and treatment are what they should be.

JAMES EWING.  
*The Gardens, Castle Menzies, N.B.*

#### CASSIA CORYMBOSA.

This pretty free-flowering species of Cassia is not so frequently met with in gardens as its merits deserve, for apart from its great beauty as a yellow-flowering greenhouse climber, it is admirably adapted for placing in the flower garden during the summer months. Many positions will suggest themselves for exposing the beauty of the plants either in the sub-tropical garden among other stately plants usually made use of, or as a group or colony near the margins of sparsely disposed shrubberies. The extreme beauty of its large corymbs of deep yellow flowers and the dark green leafage cannot but be much admired. When treated as a half-hardy shrub for the garden, cuttings of half-ripened wood will quickly root if inserted at this time, provided the cultivator has a warm pit or propagating house in which to plunge them. I find they strike more readily in autumn than in spring, though they will strike in the latter season if taken off with a heel of the old wood attached. By striking the cuttings in autumn the plants may be grown on gently all winter, thus building up a strong plant by June : before then it will not be advisable to plant them in the open. This Cassia repays liberal treatment, therefore the position intended for it should be prepared beforehand by digging out and wheeling away the soil if uncongenial and replacing with some enriched loam and old potting soil. If the soil of the garden is fairly rich and light I would advise digging in some stiffer soil, together with some rich manure.

On the approach of frost the plants must be lifted with a ball of earth if possible, and potted up for storing in the greenhouse for the winter months, partially withholding the supply of water. In February the plants should be repotted into fresh maiden soil and pruned back to wood that is ripe. Place them in humid heat to induce them to break, afterwards growing them in a somewhat cooler structure until in April or May they are placed in a sheltered part of the frame ground to harden in readiness for planting out about the second week in June. For covering a back wall of a conservatory or greenhouse this Cassia is unsurpassed. The border should be restricted if the plant is to be permanent, as over-luxuriant growth will be made at the expense of flowers. I have

this Cassia against the wall of a lofty house, and it has reached a height of 12 feet. I have seen plants 20 feet high. The border in which this is growing is 20 inches wide and 28 inches deep.

Like many other plants that used to be accorded stove treatment this Cassia has been proved to thrive equally as well and even better in a cool greenhouse, and also to assist in no small measure in the embellishment of our flower gardens during summer.

H. T. MARTIN.

#### STATICE LATIFOLIA.

ALL the Statices are deserving of cultivation, whether for the embellishment of the greenhouse or for giving variety in the flower garden. Such greenhouse species as *S. profusa* are of inestimable value for providing a wealth of blue flowers that will remain fresh on the plant for a long time : these may also be dried with other flowers of an everlasting character for placing in vases without water during the dull winter months. The past summer appears to have been favourable to the free growth of *S. latifolia*, which is perfectly hardy, and several well-established plants of this have flowered most profusely here. So distinct and beautiful have they been among other herbaceous plants that one has been tempted to leave the spikes of flowers upon the plants for a longer time than is advisable. To retain them too long is a great strain that none but strong, healthy, established plants can well support without injury. If cut when the myriads of flowers are open and dry we find them most useful for a variety of decorative work in winter.

*Stourbridge Abbey Gardens, Warwick.* H. T. M.

#### CORRESPONDENCE.

(*The Editor is not responsible for the opinions expressed by correspondents.*)

#### CORDON APPLE TREES.

[*To the Editor of "The Garden."*]

**S**IR,—I am about to plant an edging of cordon Apples along both sides of a garden walk about 1 foot from the ground. I should feel greatly obliged if you would kindly give me a list of what you consider to be the best for the purpose, size of bloom, colour of fruit, free-bearing, and hardiness to be considered before quality of fruit.

[In order successfully to grow low cordon Apple trees the varieties planted must be free growers. As the primary object our correspondent has in view is to plant his cordons for rich colouring effect of the fruit in autumn and for the charm of the flowers in spring, irrespective of quality of fruit, there is no necessity to include any weak or uncertain growers in the list. The following list includes Apples of large size, rich colouring, and handsome appearance, the flowers of most of them being large and beautifully coloured :—

*Beauty of Bath.*—A well-known early exhibition variety of moderate size and rich colouring.

*Lady Sudeley.*—An exquisitely coloured variety, of free growth, and a good cropper.

*Duchess of Oldenburg.*—One of the surest croppers, as it is one of the most highly coloured and handsome.

*Worcester Pearmain.*—This well-known and popular Apple needs no description. Its handsome crimson skin, abundant bearing qualities, and good flavour have secured for it a very high position in the estimation of fruit growers.

*Red Astrachan.*—One of the brightest and most attractive of all Apples.

*Emperor Alexander.*—For handsome appearance when ripe this variety is truly an emperor amongst Apples. The fruit is of immense size, beautiful conical shape, of a rich and handsome colour, good cropper, and a free grower.

*Washington.*—A fine exhibition variety, large, and of exquisitely delicate colouring.

*Peasgood's Nonsuch.*—This variety attains an enormous size, especially when grown as a cordon.

As a handsome exhibition variety it is one of the most highly valued. Its colour is golden, streaked with light crimson.

*Gascoigne's Scarlet.*—This is the most brilliantly-coloured Apple we possess, and from an ornamental point of view indispensable.

*Charles Ross.*—A new variety of handsome appearance. A seedling from Cox's Orange Pippin, and said to be harder and a better grower than that superb variety.

*Golden Noble.*—This distinct and noble Apple of the colour of guinea gold must not be omitted.

*King of the Pippins.*—This high-class and highly-coloured old Apple should be included.

*Lanc's Prince Albert.*—Large and handsome, never fails to bear.

*Mire du Ménage.*—One of the most distinctly coloured Apples we have. Of large size, prolific, and of a deep claret colour, densely suffused by a lovely bloom.

*Newton Wonder.*—Immense size, something like Blenheim Orange (which is one of its parents). An introduction of recent years, and destined to take its place as one of the largest, handsomest, and most valuable late Apples we possess.

*Calville Rouge Précoce.*—One of the highest coloured, and valuable for exhibition.

The list of beautiful and attractively coloured Apples might be largely extended, but the above include the best. For the beauty and profusion of its bloom more particularly we must not omit to mention the Wise Apple, Court Pendu Plat, an illustration of which was given in THE GARDEN a few weeks ago. Cordons should be grown on the English, not French, Paradise stock. See article in THE GARDEN of last week on this subject.—ED.]

#### VERATRUM ALBUM.

[*To the Editor of "The Garden."*]

SIR,—Your fine illustration of Veratrum viride in the issue of October 25 prompts me to refer to the somewhat considerable difficulty there is in dealing with Veratrums, in consequence of their prodigious growth below ground ; also to mention a singular method of natural multiplication that may not be generally known.

The Veratrum I grow is *V. album*. In a border not favourable to the deep rooting of most plants, this one, while confining its top growth for three or four years to a single spike, sends out from a solid root-stock tier upon tier of supple thong-like roots (at an angle of about 45°) of a length of about 2 feet. When soil is shaken from them the roots are too dense to do anything with ; they need to be nearly all cut away before replanting. Thus treated plants will grow away freely, but take about three years to establish themselves before producing their massive flower-stems. Seeds are uncertain of germination, and seedlings do not flower for some years.

Early in October the leaves fade and hang about the stem. Then on each of the strongest stems, about 4 inches from the ground, I find one thick green bud 1½ inches long this year and as thick as a man's thumb : from each side of the bud a thick white root runs down between the hard woody stem and the bast-like outer bark. These buds may easily pass unnoticed. They are not always so prominent or so green as this season, and the clinging leaves conceal them. In view of the difficulty of division and of seed germination it is probable that buds provide the most natural means of increase. Buds make flowering plants in the second year. My plants this year are fully 6 feet high.

DUDLEY DOCKER.  
*King's Norton, Worcestershire.*

#### SHRUBS FOR HEDGE AND GARDEN.

[*To the Editor of "The Garden."*]

SIR,—Considered as hedge or screen bushes, can you tell me the chief comparative points in Cypress, Thuja, Retinospora, and Junipers? Will they all stand pruning flat for a hedge, and is July the proper time to prune them? My preference would be for golden or silver varieties, and the hedge to be kept about 6 feet or less in height. When one sees young conifers in a nursery most of

them look very much alike, and to the uninitiated it is hard to guess whether they are dwarfs twenty years old or of the Californian big tree variety; nor do I know of any easy means of finding out from books on gardening, as conifers and evergreens are generally dismissed in a page or two of generalities, with perhaps an allusion to Lebanon and some fine Cedar the writer's great-uncle saw fifty years ago in Palestine.

WILLIAM B. WELCH.

[The Junipers, Thujas, Cupressus or Cypress, with which last the Retinosporas are now incorporated, though they are kept distinct in most gardens and nurseries, differ from each other in various botanical particulars, though to the uninitiated there is a great sameness in all of them. For hedges of 6 feet or less one of the best is Lawson's Cypress (*Cupressus lawsoniana*), which is cheap, grows quickly, and stands cutting well. The foliage of this is of a pleasing shade of green, but as you prefer gold or silver forms the best we can recommend are *Retinospora plumosa aurea* or *R. pisifera aurea*, which resemble each other in many particulars. Two other and cheaper Retinosporas, viz., *R. obtusa* and *R. pisifera*, can also be recommended for the same purpose. For taller hedges, that is to say, where 6 feet is the minimum instead of the maximum, a further choice is open to you, as the following are available: *Thuja Lobbi*, a rich and effective green at all seasons; *Thuja occidentalis*, scarcely as good as the last; and the Deodar (*Cedrus deodara*), whose drooping shoots are very pretty. In the case of coniferous plants the pruning is best done in the spring before the plants start growth, as the young shoots are particularly attractive, and if carried out in July they are cut off in the height of their beauty. After all there is no other conifer to equal the Yew as a hedge, and if you prefer the golden-leaved forms they will conform to the same rules as the ordinary kinds. Effective plants of these are, however, costly to buy, and for a hedge at a comparatively cheap rate we should recommend *Cupressus lawsoniana*. You do not say whether the place is near the sea, but as your letter is dated from Folkestone we thought it might be so, in which case there is no better hedge plant than the Tamarisk, which in summer is equal to any of the conifers, and stands cutting and sea breezes well.—ED.]

#### THE POTATO CROP OF 1902.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The interesting remarks by your correspondent "W. S." Rood Ashton, Wilts, in a recent number of *THE GARDEN* re this year's Potato crop, is a subject that ought to call forth remarks from many districts. Speaking of the Liverpool district generally, which boasts of its splendid

Potato acreage, I am bound to say that the crop is large and very free from disease; in fact, I have spoken to many farmers and have inspected their produce, the one verdict being that, considering the season, the yield is capital; magnificent samples only realise sixpence per peck in almost every shop in the city. Up-to-date has been and is yet a standard market variety. British Queen is with us a splendid Potato. It is, however, somewhat tender, and proves a fine second early variety. Pioneer and Charles Fidler are sterling varieties, and Empire, on light ground, has been a great gain.

Maincrop commands the highest price, but for two or three years the stock has been perceptibly smaller, notwithstanding the change of seed, and many large growers pin their faith on Langworthy. Abundance, too, finds a ready sale, being a most heavy cropper. Change of seed is an important factor here, the increased yield showing at once the advisability of this. New manure at one time was considered the correct thing when Potato planting; now, in some instances, an autumn dressing is given, and on land of a clayey nature works well. On light soils the use of newer manure is more suitable.

Like "W. S." I believe that much disease is caused through heavy manuring, and one has only to try experiments in this direction to justify the statement. In conclusion, there is one other subject to which I attach great importance as spreading disease, viz., too close planting between the rows. This season has been wet and cold, growth has been rampant, and the haulm has become a thicket where air and light could not possibly play their proper parts. Far different were the plants allowed more space.

Liverpool.

## THE FRUIT GARDEN.

### PEAR CONFERENCE.

**T**HIS Pear is well worth adding to a list of the best varieties, for it has several good points—it is of handsome appearance, crops heavily, and the flavour is equal to that of many mid-season varieties. This Pear was certificated at the conference at Chiswick in

as soon as possible. To this treatment a thoroughly good shaking of the boughs of the infested tree so as to bring down the injured fruit will be of service. Also spreading a coat of quicklime on a dry day beneath the infested tree and then slaking it might have a good effect in killing the escaping maggots.

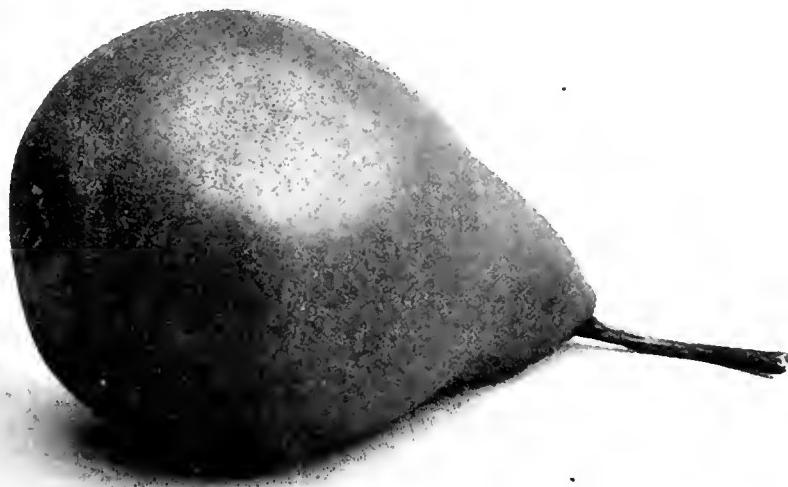

When Pears are grown in grass orchards a deal of the fallen infested fruit would be cleared off by having sheep on the ground. If the tree roots are not too near the surface the plan of skimming the surface and turning the earth with its contained pests would answer well.

The Pear leaf disease known as "blister," which is caused by a minute cylindrical four-legged mite (*Phytoptus pyri*) does great harm to Pear leafage. Where there are only a few leaves infested or the trees are small it is well to pick these leaves off and burn them as soon as the attack is observed.

Most of the insects that prove disastrous to the Apple may frequently be found on the Pear, and should be dealt with as described for Apples.

#### PLUM.

The Plum aphid or green fly (*Aphis pruni*) is to be found on Apple, Medlar, Peach, and Apricot, besides the various kinds of Plum, and is exceed-

PEAR CONFERENCE. (Two-thirds natural size.)

1885. The shape is pyriform, skin a deep green and russet colour; the tree is a robust grower, thriving well both on the Quince and Pear stocks. The fruit is in season during late October and November; when grown on a wall I should advise a cool aspect if the fruits are wanted late in the autumn. G. W.

#### INJURIOUS INSECTS AND DISEASES AFFECTING FRUIT TREES.

(Continued from page 362.)

##### PEAR.

THE Pear gnat midge (*Diplosais pyrivora*) is a very frequent trouble to Pear growers, from the damage caused by its little legless, yellowish white maggots, living in numbers inside the young Pears in their very early condition. Consequently, on the maggots feeding within the fruits the growth of the young Pears is checked and stunted, the centre decays, and the fruit cracks or dies and drops off. As preventive measures, in cases where the crop is in reach, pick off the little stunted Pears, also gather up the fallen fruit and destroy

ingly destructive. Multiplication of the insects takes place by millions, and these close up the pores of the leaves by their tenacious excretions and the mealy exudations from their bodies. They are to be found collected in numerous colonies on the under side of leaves of the young shoots, and are sometimes found in parties on the stems of the green fruit.

As a remedy, washes with a foundation of soft soap are the most desirable, because they have the great advantage of sticking in some degree to the aphides which is necessary in order to kill them.

The winter moth (*Cheimatobia brumata*) is perhaps the most injurious of all our orchard insects. In some years, when favoured by drought and heat, the mischief is widespread. The caterpillars prey on the leaves and buds of Plum, Apple, Pear, Cherry, and Nut, and sometimes on Currants. In regard to this pest it may be well to call attention to the fact that where young trees are fastened to stakes it is necessary that something be done to stop the traffic up these supports, and thence to the trees; also where bundles of sticks are tied round the trees to prevent their being gnawed by animals, the guards themselves

will probably be a source of caterpillar attack at hatching time in spring unless well looked after. The guards or stakes therefore should be well tarred and a greased band placed on the tree above the supports or protections.

The following method of grease-banding for fruit trees was suggested by the late Miss E. Ormerod, LL.D., which recommends itself by its simplicity and cheapness, a consideration when some hundreds of trees have to be attended to. The material employed is a kind of tough paper, which is used by grocers for wrapping up butter, lard, and the like, and is known as grease-proof paper. This is applied by a band, as many inches wide as is thought fit (the wider the better), being passed round the stem of the tree. The band should be cut long enough for the ends to overlap well, and these are fastened by paste. The whole is made secure by a piece of bast mat tied round the paper near each edge. This work can be rapidly and well done by women. On the paper bands the grease, on application, may be spread in any way preferred, but the best way is considered to be to lay it on with a thin, flat piece of wood, and plentifully, both as to width of band and thickness of layer.

J. J. WILLIS.

(To be continued.)

### STRAWBERRIES FOR FORCING.

By this time all Strawberries required for forcing should have had the crowns thoroughly ripened. Unless this has been carefully attended to, success and a full crop of delicious fruit cannot be guaranteed. I have this season seen plants placed under a very shady wall, where the sun could hardly reach them, and placed so thickly together that the foliage was weak and poor. Now the result in this case will be a partial if not a total failure. Strawberry plants, as soon as they are potted up, should be placed in full sun and carefully attended to as regards watering, &c. As soon as the hard weather sets in the plants may be placed together and plunged in ashes. This will prevent the pots being broken by frosts. Great care should be exercised as regards the forcing of the plants. The plants do not require too much heat: a minimum of 50°, rising to 70° in the day time, will be found to force them naturally and ensure a crop of juicy Strawberries out of season.

*The Laurels, Cain's Cross, Stow.*

### GLEANINGS FROM RECENT BOOKS.

DEEPEK KNOWLEDGE WANTED.—“I am often struck with the total ignorance the younger generation of England displays of anything connected with plants and flowers, or of country life and its pursuits. I was standing one day in a garden with a young lady, a relation of some neighbours of ours; she was here on a visit, and I remarked to her on the beauty of the Acanthus in her brother's garden. She beamed. ‘*Acanthus, Ah! do tell me, which are the Acanthus?*’ We were just then standing among them. She was a most aesthetic young woman—St. George's correspondence classes, and all the rest of it. I knew in a moment that my mention of Acanthus had touched the chord of Corinthian capitals, Greek architecture, &c., but it was odd. This young person embroidered her own dresses in the most approved high art shades, and went about in raiment of a cut and style that was the despair of her Tuscan residential relation, who was a person of very good taste in all his surroundings. But she was not a solitary example of ignorance. I was asked one day if my garden possessed any ‘Japanese Orchids.’ I have never connected Orchids with Japan, and do not recall having seen any while there, and I answered in the negative; but presently we passed a bed of Spanish Irises, and the enquirer, pointing to them, said, ‘There are the Japanese Orchids I was asking for.’ No doubt he had heard Irises called, as they sometimes are, the ‘poor man's Orchids,’ and muddled it up. I have also been told of Hortensias flower-

ing in the open in the month of March, and on going to inspect these remarkable plants found them to be the large leaved Megasea. The latest information I have had was that Larkspurs were Lupins, but I could multiply instances of astounding ignorance in regard to gardening matters of the most ordinary description among people who have presumably had some opportunities afforded them of knowing better.”—From “In a Tuscan Garden.”

## GARDENING OF THE WEEK. KITCHEN GARDEN.

**W**E have now arrived at a season of the year which, so far as the cultivation of the kitchen garden is concerned, is the least important of all. Nevertheless, there is little time to rest on our oars, and the enthusiastic cultivator of high-class vegetables can always find plenty to occupy his mind and time even in the dead of winter, if he makes up his mind to excel in this, perhaps the most important branch of gardening. It is well to bear in mind that first-class produce is not obtained by merely manuring, digging, and sowing the seed, but is the result of careful and well thought-out plans, and though some may be favoured by much more genial soils and other advantages than others, it by no means follows, unless advantage is taken of them, that the best success will be attained. As I have often pointed out, by a thorough system of cultivation almost any land may be made to produce good vegetables. A plan should be made of the garden and a site selected where each crop is to be grown next season, and as far as possible the ground treated accordingly. Endeavour to change the land annually for most things, exception being made of such as Onions, Horse-radish, and Artichokes; on no account should the Brassicas be grown two seasons in succession on the same land or clubbing is almost certain to follow. In some localities this causes much trouble, and when such is the case after the ground is turned up thorough good dressings of soot, fresh lime, cinder, and wood ashes should be given.

We are very much at the mercy of the weather at this season, especially so on wet, heavy ground, and must shape our course accordingly. Take advantage whenever it is dry and frosty to get as much wheeling done as possible, and on no account attempt to work the soil when in a wet state or the consequences will be, by the time the season comes round again for getting in the crops, instead of its being in a suitable state for receiving them it will be just the reverse. No time should now be lost in making everything as safe as possible in case of a hard winter. “Safe bind, safe find” is an old proverb which should always be borne in mind, and though in some seasons we may go to an unnecessary amount of labour and trouble, it is always best to be on the safe side. Any work which is in arrears should be pushed on without further delay. All white Broccoli should be layered or it is certain to suffer considerably after such a mild autumn.

Protecting material should be got in readiness for protecting Globe Artichokes, and some suckers potted up unless done as previously advised. Lift and store sufficient roots of Parsnips, Chicory, Salsify, Jerusalem Artichokes, and Scorzonera for a few weeks' supply, but the bulk is best left in the ground.

Pull and store all Turnips which are of a suitable size, and draw soil over the smaller ones. Mould up all Cabbages.

E. BECKETT.  
*Aldenham House Gardens, Elstree, Herts.*

### INDOOR GARDEN.

#### ZONAL PELARGONIUMS

THAT were rooted in the summer and are growing in 3-inch pots may be potted into their flowering pots. Over-potting must be avoided, as Pelargoniums flower most satisfactorily if allowed to

become somewhat pot-bound and liberally fed with liquid manures. Good fibrous loam, pulled to pieces with the hand, and dried manure, with a free admixture of wood ash and silver sand, will make the best compost. It is essential that the soil should be rammed fairly firm in potting or the growth will be sappy. Afford good drainage and water with great care during winter. Keep the plants near the glass in a light airy pit with a rather dry atmosphere. The plants should be stopped occasionally in order to encourage a sturdy growth, and all flower-buds pinched off. Show, decorative, and fancy Pelargoniums require somewhat similar treatment. Due attention must be given to the training and tying of the growth of the earliest batches. Later plants should be kept pinched, a sharp look out kept for green fly, and measures taken to eradicate this pest. Vaporising is the best remedy.

#### HUMEA ELEGANS.

Well-rooted plants should be shifted into larger sized pots. Thorough drainage and a rich porous compost are two essentials to the successful cultivation of these plants. Watering should be practised with exceeding care. Air must be admitted on all favourable occasions, as nothing is so liable to weaken the constitution of the Humea as a close humid atmosphere. Fire-heat should only be applied to keep out frost.

#### HYACINTHUS.

For the early supply of flowers the single varieties, as the buds show, should be transferred to the forcing house, according to demands. Keep the plants near the light, and employ as little heat as possible. A high temperature will cause weak growth and poor colour. Tulips withstand a higher temperature better than the Hyacinth. In any case the temperature of the forcing house should not be allowed to exceed 65°. A succession of Narcissi and Jonquils should be forced at intervals.

#### GREENHOUSE CLIMBERS.

Thin out the weak shoots of Lapagerias, retaining all strong shoots thrown up from the base. These plants should be sponged over frequently, as insect pests are liable to infest them. Roses should have any small weak growths cut hard back, but all strong shoots should be retained. The shoots of Cobaea scandens, Tacsonias, and similar climbers that have ceased to flower should be tied and rearranged.

JOHN FLEMING.

### THE FRUIT GARDEN.

#### THE WINTER MOTH.

It is now somewhat late to recommend measures to prevent the female insects ascending the stems of trees of Apples and Pears in order to deposit their eggs; it is, however, far better to take preventive measures even now than not at all, and it pays to attend to trees with short stems as well as standards. The method usually adopted is to procure grease-proof paper bands from 4 inches to 6 inches in width and sufficiently long to encircle the stems and slightly overlap. These should be made perfectly secure in such a way as will prevent a moth getting under them. Bands for the purpose and a grease preparation also are in the market, and can be readily procured. It is necessary, owing to the grease in a measure losing its adhesiveness from exposure, occasionally to re-dress the bands with it.

#### PRUNING WALL TREES.

It is advisable to commence the winter pruning upon wall trees soon after the leaves fall, and this affords a suitable opportunity to repair defective walls, their copings or trellises, and to cleanse them from injurious insects that may be there. An insecticide composed of caustic soda and crude potash, properly diluted with hot water, is now generally used. The pruning may suitably begin with Morello Cherries, but if the young wood was properly managed during summer this will not be a big undertaking. A general thinning of trees encumbered with unproductive branches should be made. Lay in young wood where there is room.

Relieve the trees also of spurs or other useless growths that unduly crowd them with foliage. Provided the superfluous shoots of the Sweet Cherry tree were carefully disbudded and pinched in the summer all that is now necessary is to shorten overgrown spurs, or thin those that are badly placed in cases where they are too thick. Young trees that have not filled their allotted space, and have had their extending shoots properly trained, and the remainder either disbudded or pinched in the summer, will only need to have their strongest leading growths shortened to a wood bud in order to cause sufficient shoots properly to furnish the trees with branches.

## PRUNING PLUMS.

Only dessert varieties, and of these more especially the best late ones, are usually given wall-space in the southern counties. In colder districts, however, more common kinds require wall protection. It is a difficult matter to keep aged trees in a fruitful condition without their spurs extending away from the wall, although much may be done by shortening and thinning to obviate this. Young growths may be in many cases trained to take the place of unprofitable branches, and in the case of cordon trees a wall may, by adopting this principle of treatment, be readily re-clothed with young wood. Young fan-trained trees that have not covered their allotted space will only require their extending shoots to be properly shortened, unless disbudding and stopping has been neglected, when the young wood must be discreetly thinned.

T. COOMBER.

*The Hendre Gardens, Monmouth.*

## ORCHIDS.

*EPIDENDRUM ENDRESIO-WALLISII.* This is, as its name indicates, a hybrid between *E. Endresii* and *E. Wallisii*. Of the numerous *Epidendrum* hybrids now available the above is one of the most pleasing, the flowers, though neither large nor showy, being very pretty, and owing to their great variation upon different plants one can scarcely believe them to be the offspring of the same parents. The flowers are produced from the apex of the stems (which grow from 1 foot to 2 feet high) in the late winter and early spring, last long in perfection, and being of a somewhat fleshy nature are not so easily affected by fog as is the case with many Orchid flowers. These, like the majority of hybrids, are easy to cultivate, and generally develop two growths in one year, and flower from both at the same time. They should be grown in pots, rather large, according to the size of the plants, as they root with exceptional freedom. They should be repotted when beginning to grow or when new roots are coming from the base of the bulbs, using as compost equal proportions of peat and sphagnum moss, or leaf-soil may be used as a rooting medium. They thrive well here in a light position in the coolest part of the Cattleya house, shaded from the direct rays of the sun at all times, and always kept moderately dry at the root at every season of the year.

*SOPHRO-CATTELEYA EXIMIA* (*C. BOWRINGIANA* × *SOPHRONITIS GRANDIFLORA*).

This is a very handsome little hybrid, dwarf and compact in growth, with flowers generally produced in winter or late autumn from the top of the bulbs somewhat before the latter have fully developed. The sepals and petals are bright purplish rose, lip dark purple-rose, with a light yellow throat. This should be grown in small pans suspended from the roof of the cool intermediate

house in spring, summer, and autumn, and placed in a light position in the Cattleya house during winter. When larger receptacles are needed transfer to others when growth begins, and use as compost peat and sphagnum moss.

*SOPHRO-CATTELEYA CHAMBERLAINII* (*CATTELEYA LODDIGESII* VAR. *HARRISONIANA* × *SOPHRONITIS GRANDIFLORA*).

Of the Sophro-Cattleya hybrids this is one of the most beautiful. It is a good companion to the other named, the flowers being comparatively large, sepals and petals brilliant rose-purple, the front lobe of the lip and the margins of the side lobes being the same colour, with the disc and throat of lip bright yellow, white towards the base. This is also of rather dwarf growth, and is best grown in pans or baskets suspended, otherwise the treatment recommended for *Sophro-Cattleya eximia* is suitable. These Sophro-Cattleya hybrids should not be kept too dry at the root during winter, as Cattleyas generally are, but should have sufficient water to keep them plump and healthy.

A NEW CHRYSANTHEMUM: LADY PRIMROSE (Colour of flowers, pale yellow.)

*ZYGOPETALUM PERRENODI* (*ZYGOPETALUM INTER-MEDIUM* × *ZYGOPETALUM GAUTIERI*).

The *Zygopetalum* hybrids are beautiful, interesting, and distinct, and the above is one of the best. It flowers generally during the spring months. The spikes issue from the base of the young growths when the latter are from 4 inches to 6 inches high, and bear from six to twelve large and fragrant flowers, having the sepals and petals purple-brown, with a light green base, lip broad suffused with purple, with dark violet-purple radiating veins, crest white, with purple ridges. This hybrid grows well here in a light position at the warmest part of the cool intermediate house, potted entirely in leaf-mould. Repotting should take place if necessary when new roots issue from the base of the young growths. These should never be allowed to suffer for want of water, though much less is needed when grown in leaf-mould.

*ZYGO-COLAX AMESIANA* (*ZYGOPETALUM BRACHYPETALUM* × *COLAX JUGOSUS*).

This is a handsome hybrid, and in bloom during

autumn. The flower-spikes issue from the base of the young growths and bear numerous flowers from 2 inches to 3 inches across: the sepals and petals are green, heavily marked with dark purple; the front lobe of the lip is white, broken with radiating lines of bright violet-blue, crest white, with violet-blue lines. It is strong and vigorous, and needs ample rooting space. It is grown here in the cool intermediate house, under exactly the same treatment as given to *Zygopetalum Perrenoudi*.

F. W. THURGOOD.

*Rosslyn Gardens, Stamford Hill, N.*

## A NEW CHRYSANTHEMUM.

## LADY PRIMROSE.

THIS new early-flowering Chrysanthemum is a primrose-yellow sport from the well-known variety white *Mme. Desgrange*. It originated in the nursery of Mr. G. Lange, Hampton. The plant grows about 3 feet high, and has handsome dark green foliage; and the one illustrated, which was growing in a 5-inch pot, carried a dozen really good blooms of a clear and pleasing colour. They are of medium size, and appear to last in beauty for a considerable time.

## MISCELLANEOUS.

## Chrysanthemums at Maidenhead.—Mr. E. F. Such.

—As most of the trade growers of the Chrysanthemum have their own speciality, so Mr. Such, of Maidenhead, may be said to pay particular attention to the early varieties, which are yearly becoming more interesting to amateurs and others who require them for border decoration. Mr. Such's collection is a large and comprehensive one, for he has altogether about 240 varieties, which he grows in the open in many thousands, and of the later sorts that require the usual glass protection he has also a goodly number for specimen blooms. Our visit was rather too late to see the earlies at their best, but enough remained for the purpose of demonstrating the great practical utility of outdoor Chrysanthemums. *Pluie d'Or*, a very free-flowering golden-yellow little Japanese, is most effective. Crimsons of various tones, but mostly rich and deep, are found in *Crimson King*,

*Goacher's Crimson*, and *Coral Queen*, a really pretty little gem. *Bronze Martinmas* is very close and neat in form, being a curious tone of pinkish buff. In whites the old *Sieur Mélanie*, *Queen of the Earlies*, and *White Quintus* are helpful, and among other varieties of this section *Mme. Desgranges*, its yellow sport *Gustave Wermig*, and a pale lilac-pink called *Glory of the Pacific* help to enliven the display. Large show varieties occupy one of the numerous glass structures in Mr. Such's establishment. Very rich and of good size is *W. R. Church*, a deep rosy plum-coloured crimson, with gold reverse. *Mrs. Barkley*, soft rosy mauve, and several older ones like *Colonel W. B. Smith*, *Edith Tabor*, the *Vivian Morel* family, make a charming colour arrangement. *Mrs. Coombes*, a pretty silvery pink and of good size, is always attractive. *Soleil d'Octobre*, soft pale yellow; *Mme. Gabriel Debie*, the deep golden-yellow of *Le Grand Dragon*; and other well known standard sorts too numerous to mention all find a place in the collection.

**Chrysanthemums at Roupell Park.**—At Messrs. John Peel and Son's nurseries the other day we were pleased to find such a grand display. In the house used for cultivating pot Vines we found quite a representative up-to-date collection. Among the finest flowers we noticed Mrs. White Popham, Mrs. F. G. Greenfield, Mrs. E. G. Fox, Mr. T. Carrington, Matthew Smith, Mrs. G. Mileham, Lord Salisbury, and Mme. Carnot. A striking feature of the grower's ability is that many of the best flowers are found on plants 1 foot to 2 feet high in 6-inch pots. We were informed that the firm have a larger demand for single-flowered Chrysanthemums. Messrs. Peel sent out many beautiful varieties, amongst those distributed last year being Bessie Conway, a lovely white; Crown Jewel, large bronzy yellow; Little Pet, soft pink; May Baylis, pale mauve; Fairy Queen, yellow ground, tinted bronze. The new varieties to be sent out this year include the following: Edgar Forbes, pale pink, very large; Roupell Beauty, a gem, dark plum; J. F. McLeod, deep pink, grand flower; Starlight, canary-yellow; Yellow Purity, straw colour, very pretty; and Pink Beauty, pale pink, large form. We were much interested before leaving to see the houses of Begonias with the last season's seed-pods ripening. Mr. Bastin assured us that it was the best seed season they had ever experienced. Judging from the enormous quantities of Begonias just being taken up, good results have evidently been had from the 100,000 seedlings planted out in May and June.

**Chrysanthemums at the Floral Nursery, Maidenhead.**—The Floral Nursery, Castle Hill, Maidenhead, was for many years an important centre for the distribution of new seedling Chrysanthemums, and was, as will be remembered, carried on by the late Mr. Robert Owen, who has now for his successor a son bearing the same name. Judging by some very promising examples of new seedlings that were in full bloom at the time of our visit, there seems to be good reason for supposing that the son will ere long follow in the father's footsteps. We were much interested in the novelties which are under trial, some of them being fine examples of exhibition blooms, but being at present unnamed cannot very well be enumerated at length. The general collection includes all the popular standard varieties of recent introduction, which are certainly in as good form as any we have seen elsewhere. Several greenhouses are devoted to the purpose of flowering the plants, and, dealing first with those of the large-flowering type, we need only mention that all the Vivian Morel family are grown and flowered in capital form, that others of more recent introduction, such as Matthew Smith, Mrs. Barkley, Miss Elsie Fulton, Jane Molyneux, Florence Molyneux (both immense white varieties), Lily Mountford, and Mrs. George Mileham quite maintain their reputation for size and colour. French seedlings are well represented by the large silver-pink N.C.S. Jubilee, which seems to be good everywhere; Mme. Gustave Henry, a big useful white; the curious green Mme. Ed. Rogers; M. Chenon de Leché, with its wonderful mingling of salmon, rose, and gold; Mme. G. Bruant, a large white suffused purple; Soleil d'Octobre, pale canary-yellow; and Mme. Marie Liger Ligneau, silvery pink, very deep in build, and fairly large in size, seems to be a more substantial flower than when we saw it first at the Paris Exhibition in 1900. Yellows are particularly rich and numerous. M. Anatole Rible is a sport from Nellie Pockett, Sir George White, Lord Ludlow, Mrs. Greenfield, R. Hooper Pearson, the richest perhaps of all. Rich purple is well shown in W. R. Church, a large solid-looking flower, beside which Australie looks dull and dingy; Ernest Bettisworth, Mrs. White Popham, and William Bardney are other varieties of the same shade. One or two large incurved varieties are notable instances of the change that is coming over this old-fashioned section. A nice little lot of early-flowering varieties in pots were making a good display of bright colour: Mme. G. Menier, very free, colour purple; Mme. Jacob, chestnut-crimson; Ryecroft Glory, another very free bloomer, deep yellow;

old Source d'Or, always bright and effective; M. William Holmes, Roi des Precoces, O. J. Quintus, and its white sport; Pluie d'Or, a fine rich golden-yellow; and many other well-known useful varieties for outdoor purposes were in the collection.

#### Chrysanthemums at Battersea Park.

If there is one feature about the show of Chrysanthemums at Battersea Park that differentiates it from all others it is the wonderfully attractive way in which the front, side and ends of the greenhouse are decorated with freely-flowered little Japanese and Pompon varieties. The kinds used this year for the purpose are worthy of enumeration, because nowadays there is an evident desire on the part of many growers to use the golde flower more and more as a decorative subject. In the Pompons, Rosinante, Aigle d'Or, Sunset, La Vogue, and Mlle. Elise Dordan are profusely flowered and help to cover the front of the greenhouse and new part of the roof. Larger forms include Elsie, L'Ile des plaisirs, Source d'Or, and an old favourite, Margot, the last-named in particular making a grand display over the entrance and exit, right up high to the ridge of the house. The collection is arranged in a large sloping and undulating bank of bloom from the rear, and is indeed one of the most attractive of its kind. There can be no service to the public at large in minutely describing in extravagant language varieties that are already well known to every grower of the flower, for so far as novelties go these are never to be met with in the displays at the parks. They are chiefly older varieties of known merit, interspersed here and there with a few modern kinds that have already figured to advantage elsewhere. Incruses are numerous, but not the modern race of mongrel-bred, ill-shaped monstrosities that are rapidly displacing the old type we used to see at our shows, Lord Alester, Baron Hirsch, Mr. Bunn, Jeanne d'Arc, White Beverley, and Golden Beverley are some examples of a type that for form cannot be beaten. For richness of colour in the Anemone group nothing can possibly surpass Descartes, a fine deep wine-coloured crimson, and in hairy kinds the palm for size and distinctness must be awarded to Hairy Wonder. Esau also belongs to the same section, but is much smaller, the colour being soft rosy pink of a silk-like hue shaded gold. Beauty of Truro is also included. In Japanese there is a floral feast of colour difficult for words to describe. The blooms range from the most massive of the big show varieties down to the smallest of the decorative kinds. We hardly know how to deal with them, but perhaps the shortest method is to arrange them in their groups of origin. Thus Continental varieties from various raisers include the ever-popular Vivian Morel, M. Freeman, a dwarf, useful pink; M. Wm. Holmes, a capital October crimson decorative variety of great service; and Calvat's varieties. Colonial growers contribute some of the finest for size and most effective in colour. Home growers are of course well represented, many of their varieties being very charming in their colours. The day of American novelties seems to be over for the present, although there is a possibility that the Chicago show of the American Chrysanthemum Society may do much to awaken a revival. A. H. Fewkes, a deep golden-yellow; William Tricker, a very useful decorative pink; Belle of Castlewood, pale pink, are seedlings of Transatlantic origin.

#### Chrysanthemums at Ryecroft Nursery, Lewisham.

As a raiser and distributor of new and choice Chrysanthemums during the past decade, few specialists, perhaps, have achieved greater success than the proprietor of Ryecroft Nursery, Lewisham. The Chrysanthemums here have never been seen in better form, the two large show houses being well filled with plants carrying blooms of all up-to-date sorts and novelties which are to be distributed in the ensuing spring. On the occasion of our visit to Ryecroft the Japanese blooms throughout the whole collection were very fine, and proved most conclusively that if the plants could do so well within the metropolitan area, how much better

they would succeed in the pure air of our country gardens. One is struck with the improved form which characterises many of the better novelties, the time when large, coarse, and rough-looking blooms were in the ascendant evidently now being past. Colour, too, has improved. Glorious and warm tones of colour appeared to prevail everywhere, and poor and washy sorts were much less frequently met with. The rich yellow blooms of Mrs. Greenfield, somewhat in the way of Phœbus, but infinitely superior, were everywhere in evidence, proving its consistency as an exhibition variety. This was distributed by Mr. Jones, as was Mrs. George Mileham, which has turned out so well already this season. Numerous blooms of this refined and handsome bright rose-pink Japanese sort were to be seen in typical condition; it is without a doubt one of the best Japanese in cultivation. The refined and deeply built blooms of Miss Evelyn Douglas impressed one with their value, the pleasing shade of rosy mauve colouring standing out distinctly. C. Penford is another very deep bloom of a reddish crimson colour with a buff reverse, and appeared to open kindly on all buds. The blooms of Baden Powell were very rich and striking, the brick-red colouring being very telling. The rich claret colour of the deep blooms of Mrs. R. Darby proved what a splendid acquisition they were for exhibition uses; this variety was distributed from Ryecroft, as was that of Mrs. J. C. Neville, a grand white Japanese flower of spreading form. These two sorts should be a great help to all exhibitors. The recently certified Mme. Paolo Radaelli convinced one that the judgment of the National Chrysanthemum Society's floral committee in this instance was not misplaced. It is a very large bloom of great depth and splendid substance: colour, pale rose on a cream ground, tinted yellow in the centre. In Bessie Godfrey, too, we have a distinct acquisition of a clear canary-yellow colour. The flowers were frequently in evidence and in splendid character; they are very full and of spreading form. A glowing crimson sent out last spring is J. C. Hill; the blooms denote distinct advance in flowers of a crimson shade, the petals being long and broad, building up a Japanese flower of reflexing form. One of the largest Japanese is General Hatton, its great breadth and the splendid substance of the petals, together with its rich golden-yellow colour, stamps this superb sort as an invaluable exhibition flower, and one of the best things our Antipodean raisers have sent us. W. R. Church here, as everywhere else this season, is doing exceedingly well, developing enormous neatly formed blooms of Japanese incurved character, with inside colouring of the deepest chestnut colour, with rich bronze reverse to the broad florets. The way the charming bright canary-yellow flowers of Earl of Arran are developing seem to prove how little is known of its excellent qualities. It is a grand flower for exhibition purposes, having petals some 7 inches or 8 inches in length, and these build a flower of a graceful drooping form. Godfrey's Pride, a bloom which caused some surprise last year, is doing splendidly here, plenty of plants carrying lovely carmine-crimson flowers being much in evidence. Mr. Jones has secured the stock of some fifteen superb Japanese sorts raised by Mr. Henry Perkins, at Greenlands, Henley-on-Thames. Many of these gems were in the first prize stands of this grower at the National Chrysanthemum Society's Aquarium show, and very telling they were. Specially grand are Henry Perkins, a very large reddish crimson flower, and on a late bud, deep rich crimson; Viscountess Cranbourne, a distinct and bright shade of canary-yellow, and most effective; this won two first prizes in vases; it is a magnificent self-coloured bloom. Countess of Harrowby, a large drooping flower, colour lovely soft pink, petals 8 inches long; Mary Perkins, a lovely chrome-yellow, certified at the October show of the National Chrysanthemum Society; Sir William Acland, another immense bloom of drooping form, colour reddish bronze; the Hon. Mrs. A. Acland, a deep rich yellow of even form, midway between Edith Tabor and R. H. Pearson in colour; Countess of Arran, a lovely refined Japanese, with petals 8 inches long, colour cerise-pink on a creamy buff

ground : Miss Cicely, a charming rich yellow, with long tubular petals—Gloriosa in type : Earl of Harrowby, a bloom of graceful build, colour rich glowing bright lake, invaluable to exhibitors : and Viscount Cranbourne, a large crimson-red. Miss Mildred Ware, the Lady Hanham coloured Mme. Carnot seedling, is also one of the good things to be sent out in the spring.

### Chrysanthemums at Brockwell Park.

Although this is a very large park and there is no other within easy distance where a Chrysanthemum show is held, the display here has to be accommodated in small conservatory attached to the old residence. So far as is possible, Mr. Curle, the superintendent, provides a very excellent display, but his efforts are of course very much cramped for want of room. In the hairy section, Esau, a pretty silky variety of soft rose and golden-yellow, is one of the most interesting, although for rivals it has the deep yellow King of the Hirsutes, and the bronzy cinnamon buff of great size and exceptional popularity, Hairy Wonder. Anemones, as in all the parks, come in for a share of attention. Descartes, a tall growing deep wine-coloured self, being at once the largest in size and richest in colour. Mrs. P. R. Dunn, a pure white, is another conspicuous instance of the decorative value of the Anemones. Incircles are best represented by Chrysanthemiste Bruant, C. H. Curtis, and Baron Hirsch, the remainder of the varieties worthy of notice being of the Japanese section. As at all the parks, Mme. Ed. Roger, the green variety, is freely grown for the curiosity it excites. The Vivian Morel group is a family that is always useful. Rosy pink is found in Mlle. Mélanie Fabre, Mrs. Coombes, William Tricker, and one or two others, and then deeper shades of purple are supplied by the inclusion of the big massive blooms of Mr. T. Carrington, Pride of Madford, Mrs. Barkley, and the like. There are many other sorts of well-known merit, but they are such as are usually grown in the parks under the care of the London County Council, a body that does not seem to encourage very much diversity of variety. Anyhow, the varieties are mostly useful for the purpose of a long display, and they seem to be highly appreciated by the visitors wherever we go.

## SOCIETIES.

### SHEFFIELD CHRYSANTHEMUM SHOW.

THE exhibition of the Sheffield Chrysanthemum Society, which took place in the historic Cutlers Hall on Friday and Saturday, 14th and 15th inst., will long be regarded as an eventful occasion in the history of the society. The display of cut blooms on this occasion was remarkable for its excellence, and rarely, if ever, has such quality been represented before. The two growers who have been invincible for years—Mr. F. S. Vallis in the Japanese section and Mr. W. Higgs in the incurved section—brought splendid exhibits from the south, and more than held their own in friendly rivalry with the exhibitors in the midlands and the north.

#### CUT BLOOMS.

The principal class in the incurved section was one for twenty-four cut blooms in not less than eighteen varieties. In this competition Mr. W. Higgs, gardener to Mr. J. E. Hankey, Fetcham Park, Leatherhead, easily outdistanced his rivals, preserving intact his five years unbeaten record. His blooms were very large, of even form and globular, and superbly finished withal. Smaller flowers of good form secured second prize for Mr. C. Crooks, gardener to the Dowager Lady Hindlip, Hadsor House, Droitwich, and heavy blooms, less neatly finished, placing Mr. C. W. Findlow, gardener to Mr. A. J. Oakshott, Oakland, Birkehead, third.

For twelve incurved, distinct, a good lot of typical blooms found Mr. Crooks leading. His flowers of Lady Isabel, Duchess of Fife, Charles Curtis, James Agate, Miss Nellie Southam, and Mr. H. J. Jones were splendidly represented. Less even big blooms secured second position for Mr. F. J. Clark, gardener to Mr. Mark Firth, Wistow Hall, Leicester. The same positions were maintained by the two last mentioned exhibitors in the class for six incurved blooms, distinct.

The chief event in the Japanese section was the competition for prizes in the class for twenty-four Japanese blooms, in not less than eighteen varieties. Mr. F. S. Vallis, Bromham, Chippenham, asserted his superiority in this instance,

winning in grand style with large and heavy blooms of good colour and beautiful finish. Rarely indeed, has such superb quality been seen before. The second prize winner came as a surprise, few persons being aware that Mr. Higgs was so good a grower of the Japanese flower. His was a beautiful and bright exhibit, and contained many flowers of great merit. Third prize was placed to the credit of Mr. A. Alderman, gardener to Mr. J. D. Ellis, Sparken House, Worksop.

In the class for twelve Japanese blooms, distinct, Mr. Vallis was again found leading with a beautiful lot of high class flowers. Mr. C. Crooks, with rather smaller flowers, was second, and Mr. Clark third. Again did Mr. Vallis lead, and this time for six Japanese blooms, distinct. They were a fine lot, E. Molynex being splendidly shown with others. A smaller set won second prize for Mr. Clark, who in turn was followed by Mr. Crooks.

Anemones, large flowered, were represented by one exhibit only. This came from Mr. R. Agar, gardener to Mr. S. Roberts, M.P., Queen's Tower, and they were beautifully shown. Equally good was the only exhibit of six reflexed blooms, distinct, and this was exhibited by Mr. C. Scott.

Five societies in affiliation with the Sheffield society competed for a cup and good cash prizes, in a class for twelve incurved and twelve Japanese in not less than eighteen varieties. The Chesterfield Chrysanthemum Society led with a heavy exhibit of Japanese blooms and somewhat indifferent incurved flowers. Good incurved and poor Japanese blooms placed the Sun Inn Chrysanthemum Society second; last year's winner, the Nether Hallam Chrysanthemum Society, being awarded third prize.

In the special prizes for vases, arranged for decorative effect, the exhibitors have much to learn, the competition, however, was good, and proved that it was the beginning of better things. The district classes for cut blooms were well contested, and some highly creditable blooms were shown by the members. Japanese and incurved were well balanced in so far as regards quantity and freely-flowered sprays of Pompons made a welcome change in the display. Successful exhibitors in this section were Messrs. T. Lucas, R. Agar, C. Scott, A. Alderman, T. J. Nelson, N. Buxton, and others.

Groups open to the district (radius of twenty miles), composed of flowering and foliated plants, made an attractive display. That from Mr. Sheridan, gardener to Mr. J. Bassett, Endcliffe Crescent, was a good first. Well coloured foliage and flowering plants were pleasingly grouped and made an effective display. A bold and imposing group of high merit secured second prize for Mr. E. Austin, Berry Hill, Chesterfield.

Five similar groups, 40 feet square, with semi-circular fronts, open in this instance to amateurs and cottagers, were quite a feature. That securing first prize for Mr. C. Cook, Wardsend, was a capital arrangement of bright foliage plants, Chrysanthemums, and a few other dowering plants; Mr. P. T. Burton was a creditable second, and this was closely followed with a group from Mr. H. Headland, Pittswood Gardens.

Table decorations were interesting, though hardly up to the usual standard. With pink Tea Roses, Lily of the Valley, Begonia, Gloire de Lorraine, and appropriate foliage Mr. Sheridan was first; a pretty table placed Mr. J. Marsden, gardener to Major Blake, Mylnhurst, Eccleshall, second, and Mr. W. Donaldson, Meersbrook, was third.

Trade exhibits were well carried out. Messrs. Shaw and Sons, 16, Broad Street, Sheffield, had a splendid group of fine foliated plants. From Mr. S. W. Seagrave, Sheffield, also came a superb group of highly coloured Crotons and other foliage plants with Chrysanthemums. The two above exhibits each received a gold medal, as did the comprehensive display of dessert fruits and floral devices and designs, very ably arranged and displayed by Messrs. W. Artindale and Son, 90, High Street, Sheffield. Harps, wreaths, crosses, chaplets, hand-baskets, &c., were beautifully executed. Messrs. John Peed and Son sent a splendid collection of Apples and Pears, for which they received a silver-gilt medal.

Chrysanthemum novelties were shown by Mr. H. J. Jones, Ercroft Nursery, Lewisham, to whom certificates were granted for Japanese Henry Perkins, Edith Smith, and Mrs. F. Grimwade. Novelties also came from Messrs. Wells and Co., Limited, Redhill, and certificates were granted to General Hutton and F. S. Vallis. To Mr. W. Housley, the courteous and able secretary, much praise is due for the excellence of the arrangements of the show, and his efforts were ably supported by an enthusiastic body of workers on the committee.

### EDINBURGH EXHIBITION.

In the Waverley Market the annual autumn show was held on the 13th and 14th inst., and was a great success, no less a sum than £327 being taken at the doors on the first day. Taken as a whole it was one of the best shows seen this season. Fruit was exceptionally good, Grapes in particular; vegetables numerous and good; trade exhibits adding to the interest of the display in no small degree. Mr. Long had everything in order as far as the arrangements were concerned.

Cut blooms were numerous, over 2,000 being staged in the various classes set apart for them.

#### VASE CLASSES.

Nowhere can so many classes be found exclusively for blooms arranged in vases as here. The principal class is that for twenty varieties, three blooms of each, for which handsome prizes were offered, consisting of the City of Edinburgh Victoria Memorial piece of plate value £20, with £10 added. Seven competed, making a grand display. Mr. T. Lunt, gardener to Captain Stirling, Keir, Dunblane, was once more successful, winning premier honours with an excellent set of blooms. To a bloom of Princess de Branca, a charming white-flowered variety, was awarded the prize for premier bloom in the show. Mr. R. Kenyon, Woodford, Essex, was a very close second, with extremely fine flowers; Mr. Nicoll, Rossie, Forgaudonoy, a good third.

For the Scottish Challenge Cup eight competed, showing the deep interest taken here in this class, which is for twelve varieties Japanese, three of each. Mr. J. Cumming, Grantully Castle, won quite easily with a pleasing display; Mr. L. McLean, Alloa, a good second; Mr. D. Nicholson, Strathallan Castle, third.

For six blooms, each of four varieties, Japanese, Mr. D. Nicoll won premier position; Mr. W. J. Norman, Rosehaugh, Ross-shire, third.

For two varieties, six of each, Lord Ludlow and Mrs. Milneham in almost perfect condition won for Mr. Kenyon the leading position; Mr. A. McInnes, Eskhill, Inveresk, second; with Mr. D. Kidd, Carberry House, Musselburgh, third. Mrs. J. Lewis won for Mr. D. McKay, Viewbank, Lasswade, the leading place for six Japanese, any one variety; Mr. C. Harris, Parton, Carlisle, second.

For twenty-four Japanese, any varieties, arranged in four vases, eleven competed, making a bold display. Mr. T. Lunt won with typical examples of popular varieties; Mr. D. Kidd second; Mr. McLean third.

For four vases, three blooms in each, Mr. W. Lumley had the best of six sets; Mr. R. Whannel, Drumhouse, second.

Single-flowered varieties were a distinct failure as regards the number of competitors taking part this season as compared to earlier shows.

Japanese, staged on the orthodox stands, were plentiful. For twelve distinct, Mr. Kenyon secured the premier award with good blooms; Mr. Lunt was a close second.

Incurved varieties were but moderately staged. For twelve distinct, Mr. Martin, Corndean Hall, was the only exhibitor, and was rightly awarded first prize. Mr. Martin also won for six varieties. In the class for six blooms, any one variety, the competition was of a keener nature. Mr. W. Moir, with J. Agate of medium size, won premier place.

This society offers a silver medal for the best new Chrysanthemum not in commerce. To Mr. W. Duckham, incurved Japanese, rose-pink in colour, belonging to Messrs. Wells and Co., Earlswood, Redhill, this award was made; the second prize also falling to this firm for incurved Pantia Rallii.

Plants were staged mainly in an undeveloped condition, showing the ill effects of the backward season. For six specimens, Mr. W. G. Mitchie, Boroughfield, Edinburgh, was first. Single-flowered varieties were much more freely flowered, Mr. Pullman winning for a single specimen with one of Miss Rose, also for yellow and bronze-flowered varieties.

For a group of miscellaneous plants, including Chrysanthemums, arranged for effect in a space 20 feet by 10 feet, there were but two exhibitors. Mr. G. Wood won the leading position with a meritorious display; Mr. P. G. Hunt, Landsdowne House, Murrayfield, second.

Fruit made a good display. Grapes were especially well represented. For four bunches, distinct, Mr. L. Leslie, Pitcullen House, Perth, won the first prize with Muscat of Alexandria, Gros Colman, Appleby Towers, and Alicante; Mr. D. Kidd second. For two bunches, one black and one white, Mr. A. Kirk, Alloa, was the premier prize taker. Muscat of Alexandria was capitally staged by Mr. Kirk in the class set apart for that variety; Mr. D. Kidd second. Mr. Kirk also won for two bunches, any variety, with Cooper's Black, quite perfect in finish.

For a collection of fruit, eight varieties, Mr. Kidd won with good Grapes, Apples, and Pears; Mr. McIntyre, The Glen, Innerleithen, second.

A new class was this year added to the schedule by this association. The handsome prizes of £20, £15, and £10 was offered for the most effective exhibit of bouquets, wreaths, &c., known as floral work, Messrs. Todd and Co., art florists, Edinburgh, being the only competitor, and were awarded the premier prize for a charming display.

Trade exhibits were numerous, adding much to the interest of the show. A gold medal was awarded to Mr. W. J. Godfrey, Exmouth, Devon, for a handsome display of Chrysanthemums, Carnations, and zonal Geraniums, embracing many novelties, mainly of his own raising. Messrs. Wells and Co., Earlswood, Redhill, had a small exhibit of new Chrysanthemums, yet containing many instructive new varieties. Messrs. Dobbie, Rothesay, had much the best collection of Potatoes yet seen in Edinburgh, quite fifty baskets of choice varieties, all of handsome appearance. Messrs. Isaac House and Son, Bristol, had Violets in quantity. Messrs. G. Boyes and Co., Aylestone Nurseries, Leicester, Carnations of brilliant colouring and capital quality. Mr. John Downie, 144, Prince's Street, Edinburgh, shrubs in quantity, arranged tastefully in the body of the market.

### ROYAL HORTICULTURAL SOCIETY.

#### DRILL HALL MEETING.

##### ORCHID COMMITTEE.

PRESENT: Harry J. Veitch, Esq. (chairman), Messrs. J. O'Brien, de B. Crawshaw, Norman C. Cookson, Frank A. Rehder, N. F. Bilney, James Douglas, John Cypher, H. J. Chapman, F. W. Ashton, G. F. Moore, E. Hill, J. W. Odell, W. Boxall, W. H. Young, W. H. White, H. A. Tracy, H. Ballantine, H. Little, and Jeremiah Colman.

Captain Holford, C.I.E., Westonhirt, Tethbury (Orchid grower, Mr. Alexander), was awarded the large gold medal for a magnificent display of Orchids, the group filling half one of the long tables. In the centre was a splendid plant of Cattleya bowringiana, bearing ten grand spikes of flowers. On either side were small groups of *Oncidium varicosum*, very brilliant yellow, and close by were three plants of *Cypripedium insigne* Harefield Hall variety, one bearing four flowers, one having two, and the other a solitary bloom; *Vanda cerulea*, *Cypripedium* in great variety, *Laelio-Cattleya* *ingrami*, *Cattleya labiatissima*, *L.C. bletchleyensis*, and *Cymbidium tracyanum*, a splendid plant carrying three grand spikes of flowers. The chief interest, however, of this exhibit was in the choice collection of *Cypripediums*. The following, among others, were included: *C. insigne montanum aureum*, *C. i. lucidum*, *C. i. sanderaeum*, *C. i. Sanderae*, *C. i. Westonbirt var.*, *C. i. dormanii*, *C. i. leeanum superbum*, *C. i. l. giganteum*, *C. i. Ethel*, *C. i. citrina*, and *C. i. leeanum Low's variety*.

Messrs. James Cypher and Sons, Chelteham, had an excellent display of Cypripediums in many beautiful varieties. We noticed *C. insignis* Sanderæ, *C. i. Ernestii*, *C. i. Harefield Hall* variety, *C. Niobe*, *C. leeanum* vars., *C. Fascinator*, *C. arthurianum*, *C. i. Chantini*, *C. leeanum* virginalis, *C. nitens*, *C. leeanum aureum*, &c. Silver-gilt Flora medal.

Messrs. James Veitch and Sons, Limited, Chelsea, exhibited several choice Cypripediums, notably *C. insignis* Harefield Hall variety, *C. i. Sanderæ*, *C. Actaea*, as well as a collection of handsome hybrid Cattleyas and Lælio-Cattleyas. *L. C. haroldiana superba* (*L. tenebrosa* × *C. hardiana*), *L. C. C. G. Röbling* (*L. purpurata alba* × *C. gaskelliana*), *L. C. Pallas*, *L. C. dominiana langleyana*, *L. C. Terentia* (*L. crispa* × *C. bicolor*), &c. Silver Flora medal.

Messrs. Sander and Sons, St. Albans, showed a group of Orchids that contained much of interest: for instance, *Cymbidium tracyanum*, *L. C. Decia*, *L. C. bowringii*-Clive, *Masdevallia macrura*, *L. C. blanchleyanum*, *Cypripedium insignis* *leeanum*, *Odontoglossum tripudans* - *crispum*, *C. Transvaal superbum*, *Laelia pumila* var., *Miltonia leopoldiana*, *Dendrobium formosum giganteum*, *Oncidium crispum*, var., &c. Silver Banksian medal.

N. C. Cookson, Esq., was given a silver Banksian medal for small group of orchids that contained *Calanthe Triumphantis*, *Cypripedium Chapmanii* and *C. insignis* Harefield Hall var., *Calanthe Kenneth*, *Cattleya labiata* *oakwoodensis*, &c. Silver Banksian medal.

W. P. Burkinshaw, Esq., The West Hill, Hessle, near Hull, showed *Cypripedium insignis* Harefield Hall variety, *C. i. Hessei* variety, *C. gowerianum magnificum* Hessei var., and *C. x. prospero major* (*C. insignis* Sanderæ × *C. spicerianum*). Vote of thanks.

Messrs. Hugh Low and Co., Enfield, showed *Cypripedium insignis* Sanderæ (beautiful colour), *C. i. Harefield Hall* variety, *C. leeanum magnificum*, and *Cattleya labiata* *americana*.

*Lælio-Cattleya Marie* (*C. Warneri* × *L. digbyana*) was sent by the Right Hon. J. Chamberlain, M.P., Highbury, Birmingham (Orchid grower, Mr. J. Mackay).

Baron Schroder, The Dell, Egham (gardener, Mr. H. Ballantine), exhibited *Odontoglossum Rolfei* var. and *O. Harryano-crispum* var. *giganteum*, both plants bearing excellent spikes of handsome flowers.

*Dendrobium wardianum* Fowleri was well shown by J. Gurney Fowler, Esq., Glebelands, South Woodford (gardener, Mr. J. Davis).

J. Wellesley, Esq., Westfield, Woking (gardener, Mr. J. Gilbert), sent a plant of *Vanda coerulea* bearing a raceme of rich blue flowers, also *Lælia Gilbertii*, a natural hybrid between *L. tenebrosa* × *L. elegans*.

A botanical certificate was given to *Bulbophyllum Eriescum*, sent by the Hon. Walter Rothschild, Tring Park (gardener, Mr. E. Hill).

#### CERTIFIED ORCHIDS.

*Lælio-Cattleya Thorntoni var. grandiflora*.—*Lælio digbyana* and *Cattleya gaskelliana* are the parents of this lovely hybrid. The lip, in which lies the chief beauty, is very large, beautifully fringed, and of a rose-lilac colour, except for a mass of pale greenish yellow in the centre, reaching beneath the whole of the column. The sepals and petals are a soft rich lilac, tinged with pale buff. The colouring of this flower is very beautiful and effective. From Messrs. James Veitch and Sons, Limited, Chelsea. First-class certificate.

*Lælio-Cattleya statteriana superba*.—A flower of distinct colouring, the result of a cross between *Cattleya labiata* and *Lælia Perrinii*. The sepals are a clear pale lilac, the petals lilac, slightly suffused with rose. The lip is of a rich purple, and stands out strikingly by the pale-coloured sepals and petals. From Messrs. James Veitch and Sons, Limited, Chelsea. Award of merit.

*Cattleya vigeriana*.—M. Ch. Maron, Bruxelles, France, exhibited this hybrid Cattleya, which was obtained by crossing *C. aurea* and *labiata* *flammea*. A flower of rich and lovely colouring has resulted. The sepals and petals are deep rose-purple; the front portion of the lip is of a deep velvety purple, and the throat lined with white upon a ground of gold and purple. Award of merit.

*Calanthe Triumphantis*.—This is a secondary hybrid, whose record is not really known. It is, however, a supposed cross between *C. Oakwood Ruby* and one of the hybrids of *C. vestita*. Except for the two outer sepals, which are almost white, the flower is a dull rosy red throughout. From N. C. Cookson, Esq., Wylam-on-Tyne (gardener, Mr. H. J. Chapman). Award of merit.

*Lælio-Cattleya × Clive var. Sanderæ*.—The parents of this hybrid *Lælio-Cattleya* are *L. C. Clive* × *Lælia pumila*, and the result of the cross is a well-formed flower of medium size, whose sepals are white, the broad petals tinged with rose. The lower portion of the lip is rich purple, the throat, whose upper portions overlap, being beautifully lined with yellow and purple. Shown by Messrs. Sander and Sons, St. Albans. Award of merit.

#### FRUIT AND VEGETABLE COMMITTEE.

Present: George Bunyard, Esq. (chairman), Messrs. J. Cheal, S. Mortimer, Alex. Dean, Edwin Beckett, Horace J. Wright, W. Gleeson, H. Markham, J. Willard, F. L. Laue, G. Norman, James Smith, A. H. Pearson, W. Poupart, and Geo. Wythes.

Messrs. J. Peed and Son, West Norwood, S.E., were given a silver Banksian medal for a collection of hardy fruit, no less than 150 dishes being shown. Many of them were excellent, while some lacked colour, owing, no doubt, to the sunless season.

A new Melon was shown by A. W. Sutton, Esq., Reading. It was a green-fleshed variety of very good quality; the committee asked for this Melon to be again submitted earlier in the season.

Mr. J. Crook, Forde Abbey, Chard, sent some splendid fruits of Winter Nelis Pear.

Messrs. James Veitch and Sons, Limited, Chelsea, showed their new November Raspberry in splendid condition.

Mr. G. Reuthe, Feltham, sent remarkably good Quinces.

Messrs. Wallace and Co., Colchester, sent two dishes of excellent Allington Pippin Apples.

Mr. Lovelock, Brockhampton Park, Hereford, exhibited some grand dishes of Pears.

Vegetable Marrows of a roundish shape were shown by Mr. W. Edwards, Weybridge.

Messrs. James Veitch and Sons, Limited, Chelsea, exhibited a collection of Borecole or Kales. They included the new Sprouting, Veitch's Exhibition, variegated and coloured Kales, and others.

Tomato Italian Wonder was shown by Sir Walter Gilbey, Bart. It is a pretty fruit, of good quality, and very freely produced.

#### NEW FRUIT.

*Langley Crab*.—This is a beautiful, rather small fruit, the result of crossing John Downie Crab with Apple King of the Pippins. It is of a pretty yellow colour, very free fruiting, of not unpleasant flavour. It will doubtless prove a valuable addition to the ornamental crabs. From Messrs. J. Veitch and Sons, Limited, Chelsea. Award of merit.

#### FLORAL COMMITTEE.

Present: W. Marshall, Esq. (chairman), Messrs. C. T. Drury, George Nicholson, R. Dean, J. Jennings, W. Howe, G. Reuthe, C. Dixon, H. B. May, R. W. Wallace, C. R. Reuthe, W. Bain, Chas. Jeffries, H. J. Cutbush, R. C. Noteout, C. E. Shea, E. H. Jenkins, Chas. Blick, Harry Turner, G. Paul, E. Mawley, J. H. Pitt, J. Fraser, J. Hudson, H. J. Jones, and the Rev. F. Page Roberts.

The collection of Platyceriums from Messrs. J. Hill and Son, Lower Edmonton, was of its kind one of the most interesting and remarkable ever shown at the Drill Hall.

The group was excellently staged, and represented the best cultivation; indeed, it would hardly be possible to surpass in their great beauty and variety of forms the plants exhibited. Many were grown in an unusual way—in pots, and in this manner demonstrated a new value from the decorative point of view. Some very fine pieces were shown, notably a possibly unique example of *P. grande*, the erect fronds of which were nearly 3 feet high and with a spread of some 4 feet. The drooping, forked, fertile fronds were also of interest, and in the pale green of the mature fronds contrasted well with the glaucous examples of *P. Veitchii* immediately below. This last is quite rigid in habit and very distinct. In point of hardiness and graceful beauty *P. alpestris* still takes the lead. *P. Hillii*, a form of the last, is a variety less drooping and with broader fronds, the lobes deeper, and cut into more numerous segments. *P. atropurpurea* was well shown, while the rare *P. angolense* was also represented. Small and large examples of each were shown, and in the elevated group the plants showed to good advantage. Silver-gilt Flora medal.

Messrs. Cannell and Sons, Swanley, set up a splendid lot of plants of *Begonia Gloire de Lorraine* and its white variety *Turmfeld Hall*. The former is unmistakably the more showy kind in the dull dark days of winter. Fine bushes, well grown and abundantly flowered, these were indeed very fine examples. Some excellent Chrysanthemums were also staged.

Mr. H. J. Jones, Lewisham, had a magnificent display of Chrysanthemums in bold vases and groups. In the centre tall vases were filled with gold, crimson, and silver rose-coloured kinds, while the corners were supported with grand vases of Dorothy Pywell, a very good white, broad in petal, and of a crispness that denotes good keeping properties. Another grand white is Mrs. J. C. Neville, flowers large, broad and deep, and very pure; Mrs. E. Roger, green-white; Mrs. Greenfield, gold; General Hutton, fine yellow; Lily Mountford, silver and rosy purple, very fine; Dolly Glade, a grand white; H. J. Gillingdon, a yellow Western King; Miss Jessie Cotté, a fine bronze, freckled with gold, a sport from Etoile de Lyon; Mrs. F. Hudson, a fine incurved white; Viscountess Cranbourne, a rich gold, very stiff in petal; William Higgs, rich bronze; Mrs. Emma Fox, red-crimson, and many more. Small kinds, as Pompoms and others of a decorative character, were freely interspersed with Palms, Ferns, and other material of a useful character. Silver-gilt Banksian medal.

From Messrs. Wells and Co., Limited, Redhill, came a beautiful arrangement of Chrysanthemums, single, decorative, and large-flowered kinds in great abundance and of sterling merit. Singles in large vases in groups made a fine background. Among the large flowers we noted such fine things as Mrs. E. Thirkell, gold; Pantia Ralli, bronze; W. R. Church, crimson; Lalia Filkins, a fine silvery rose, very beautiful and refined; Mrs. Barkley; General Hutton, a fine big yellow; F. S. Vallis, rich yellow, very beautiful in form; Ben Wells, a big white; Mrs. T. W. Pockett, yellow; and many more. Market Red is a fine variety for cutting, and rather free, with long stems. Silver-gilt Flora medal.

Messrs. James Veitch and Sons, Limited, Chelsea, filled one long table with their showy winter-flowering Begonias, a really grand sight at this season of the year. Of those shown, E. Agatha, obtained by crossing *B. socotrana* and *B. Moonlight*, is a compact *B. Gloire de Lorraine*, very free and dwarf, and of exquisite colouring; B. Winter Perfection is a very showy kind, rich in colour, and most profuse flowering; B. John Heal is a deep rose-carmine *Gloire de Lorraine*; B. Mrs. Heal is the largest and most showy of the lot; B. Julius semi-double pink; B. Success, a distinct flower of a deep rose and carmine; and B. Agatha compacta, which is a dwarfer *Gloire de Lorraine*, the plants profusely flowered and about 9 inches high. A group of the showy Mexican *Jacobinia chrysostephana* with golden-orange flowers tipped green made a rich display, and for winter flowering is a most effective subject; good flowering examples were less than 8 inches high and very rich in the mass. Silver-gilt Banksian medal.

Mr. H. J. Jones showed well-grown plants of *Begonia Turnford Hall* and *Gloire de Lorraine*, together with Palms and Crotons.

From Lady Tweedmouth, Brook House, Park Lane, came a charming lot of blooms of *Malmaison Carnations*, the varieties *Princess of Wales*, *Old Blush*, and Sir Charles

Freemantle indicated by their size as much as their rich colour the best possible cultivation. We have rarely seen such fine flowers on any occasion, and of the Princess of Wales in particular. Vote of thanks.

Carnations in cut state were charmingly shown by Messrs. W. Cutbush and Sons, Highgate, and arranged with a little foliage in vases made quite a pleasing departure. There were some dozen or so kinds such as G. H. Crane, scarlet; Inchess of Portland, pink; Gov. Roosevelt, crimson; Glacier, pure white; Hon. H. Fellowes, rose-scarlet; Stella, white-flaked scarlet; Harry Fenn, crimson; Novelty, yellow ground; Sir Hector McDonald, light striped, and others.

Single Chrysanthemums were prettily shown by G. Ferguson, Esq., Weybridge (gardener, Mr. F. W. Smith), the majority being seedlings raised by the exhibitor. Achilles, golden-bronze; Belle of Weybridge, chestnut-crimson; Lucius, bronze; Bellis, semi-double; and Lavinia, reddish chestnut, were among the good ones. Coloured foliage and berry-bearing plants strewn among the flowers assisted in the general display.

A group of *Epiphyllum delicatulum* was shown by Messrs. William Bull and Sons, of Chelsea. This is the plant shown under the name *E. truncatum* Princess in November, 1898, when Messrs. Bull were awarded a first-class certificate for it. It has now been found to be a true species, and the name first mentioned having been bestowed upon it by the antiquities at Kew, the plant will henceforth be so called.

From Mr. Edward Mawley, Rosebank, Berkhamsted, came a beautiful lot of garden Roses that, considering their lateness, were of exceptional merit. There were at least a dozen kinds; these included Hybrid Perpetuals, Teas, and Hybrid Teas, and were very much admired. Vote of thanks.

Messrs. Barr and Sons, Covent Garden, contributed hardy flowers, as *Aster Amellus Framfield*, *Iris stylosa*, *Schizostylis coccinea*, *Aster grandiflora*, together with bedding *Violas* and decorative Chrysanthemums. Varieties of *Lupinus polyphyllus* were also shown. A very interesting exhibit, also from Messrs. Barr, consisting of four cases of wax models of the flowers of Narcissi. Some fifty or more of the newest kinds were thus shown, and to say the flowers were perfectly represented is but doing them the merest justice. Only one opening was left for improvement, and that the addition of the foliage to each. This would certainly have enhanced the value of this wonderful collection.

#### CERTIFICATE PLANTS.

A first-class certificate was awarded to:—

*Jacobinia chrysostephana*.—This showy Acanthad was formerly described under the generic name of *Cyrtanthera*. It is brilliantly attractive, a fact which the group exhibited on Tuesday fully demonstrated. The bright orange-golden flowers, disposed in a terminal or clustered corymb and standing well above the leaves, produce a rich effect rarely seen so late in the year. The ovate-acuminate leaves are distinguished by the vivid colouring of the mid-rib and the nerves on the under surface. The plant is a comparatively recent introduction from Mexico, and is well suited to the general conditions of the warm greenhouse. As a decorative plant grown in small pots this *Justicia* should prove of great value. Exhibited by Messrs. James Veitch and Sons, Limited, Chelsea.

The following received an award of merit:—

*Begonia Agatha compacta*.—This dwarf and compact plant is derived from *B. socotrana* and *B. natalensis*, the last a small white-flowered kind with some resemblance to *B. Moonlight*. The present novelty as shown on Tuesday fully demonstrated. The bright orange-golden flowers, disposed in a terminal or clustered corymb and standing well above the leaves, produce a rich effect rarely seen so late in the year. The ovate-acuminate leaves are distinguished by the vivid colouring of the mid-rib and the nerves on the under surface. The plant is a comparatively recent introduction from Mexico, and is well suited to the general conditions of the warm greenhouse. As a decorative plant grown in small pots this *Justicia* should prove of great value. Exhibited by Messrs. James Veitch and Sons, Limited, Chelsea.

*Chrysanthemum F. S. Vallis*.—A flower of the largest type and good build generally. The soft yellow tone is very pleasing and the gracefully drooping florets are elegantly arranged. Shown by Messrs. Wells and Co., Limited, Earlswood, Redhill.

*Chrysanthemum Lalia Filkins*.—This is a Japanese of large size with drooping florets. The colour is a soft silvery rose and very pleasing. The variety may not inaptly be described as a refined and improved Vivian Morel. Shown by Messrs. Wells and Co., Limited, Redhill.

*Chrysanthemum Belle of Weybridge*.—This was set up as a single kind, but it will not justly pass as such; as a decorative variety it is showy and good. The colour is warm bright crimson-red, and with the golden centre makes an unusually attractive flower. Exhibited by G. Ferguson, Esq., Weybridge (gardener, Mr. F. W. Smith).

*Chrysanthemum Miss E. Seward*.—A Japanese incurved, with the rich colouring of the old *Jardin des Plantes*, yet perhaps less rich. It is, however, of much merit from the colour point of view, and the flower is well built. Shown by Mr. E. Seward, Hanwell.

*Carnation Viscous Kitchener*.—A winter or tree-flowering variety, with large shapely white flowers, lightly yet freely striped with scarlet. The flowers are supported on good stems, and freely produced. They are also nicely scented. Shown by Messrs. William Cutbush and Sons, Highgate, N.

#### WOOLTON GARDENERS' SOCIETY.

A MEETING of this society was held on the 6th inst. at the Mechanics' Institute, when Mr. T. Carling was voted to the chair. The subject for discussion was "Gardening: Past and Present," introduced by Mr. R. McHardy, who reviewed from early times the various fashions as they changed, with a notice of the many new introductions from various parts of the world. Many noted firms were mentioned who had done much by these means to enrich our gardens. A word of appreciation was also given to the many eminent hybridisers who had done much to increase the beauty and wealth of the vegetable kingdom. An interesting discussion followed, when the advantages of cheap glass structures well heated were compared with the difficulties our forefathers had to contend with. A cordial vote of thanks was tendered to the lecturer and chairman.

[NOVEMBER 29, 1902]

## ROSE SHOWS IN AUTUMN.

DURING the past autumn the fortnightly meetings of the Royal Horticultural Society have shown that the Rose is a flower of the later months as well as June and July, when Rose displays are held throughout the United Kingdom. But it is surely possible for the National Rose Society to encourage the planting of Roses for autumn by holding an exhibition directly under its auspices in September, when we are assured of a keen competition in the Tea and Hybrid Tea divisions, and teach those who know not the value of the flower in autumn that its colouring is richer and the fragrance sweeter than in the sultry days of summer.

Letters reach us of the dulness and positive wearisomeness of exhibitions generally at the present day, and Chrysanthemums in rigid lines are becoming monotonous and depressing. Makers of schedules seem absolutely devoid of anything approaching originality, but frame their prize lists upon one apparently unalterable plan, till those who love the flower for its own sake visit the shows no longer, but seek the garden where bushes are heavy with bright bloom almost to the threshold of winter.

The Rose is a flower of autumn, and an exhibition by the National Rose Society will be helpful to those who are ignorant of the many varieties in full beauty at that season, when the flowers are dyed with richer colours and last longer than when gathered earlier in the year. Till a few days ago the garden of the writer was full of flowers; here Marie Van Houtte, more beautiful than in summer, there the glorious Caroline Testout, and many others, the shoots thick with buds and opening blooms.

A little path lined with Lavender and China Rose was a sunny spot one late October day when the Rose was bright with those fresh fragrant flowers which gave to many a garden of the past its sweetest beauty. This meeting of Lavender and monthly Rose is a delight to all who treasure simple yet beautiful English gardening, and when this old garden Rose is still gay many of the more recent varieties or hybrids offer countless flowers which are never more winsome than when bathed with the dew of an autumn morn.

The National Rose Society will make no false step when it institutes, modestly at first, an autumn competition, and the exhibits will

probably keep fresh and attractive throughout the day, owing to the greater substance of the petals in September and early October. There would probably be no difficulty whatever in holding the exhibition in the Drill Hall, Westminster; in fact, the show should be on similar lines to that of June.

We hope raisers of new Roses will strive to obtain climbing varieties that will last longer in beauty than the majority of those in existence at the present day. A blaze of colour for a few days is not satisfying, and it is sometimes lost unless watched for, one storm perhaps spoiling the picture, or through a brief absence from home the feast of flowers is missed.

Single Roses are with us for a brief time, the petals flutter to the ground, and, unless the Rose has an abundance of hips, withered leaves and gaunt stems are the reward for another twelve months. Wake up raisers and work in this direction, and in so doing confer a blessing on those to whom the Rose is the flower of flowers, whether as a climber, circling pergola or wreathing fence, or as a bush making splashes of colour in bed and border.

We are not insensible of the excellent work accomplished in the past by the National Rose Society. Its influence has been immense, its shows a pure delight; but by extending its work in the way indicated the value of the flower for autumn will be more widely recognised.

## THE HORTICULTURAL HALL PLANS.

We have received several letters in reference to our remarks of last week, but we have no desire to open our columns to a discussion upon the subject. We do not, however, wish to hinder the progress of the Horticultural Hall in the slightest degree, and ask those who approve of its object to support the appeal of the Council for funds.

Our criticism was an honest one, and we are sorry that the design has been accepted. We agree with the words of one writer: "Every chance wasted and commonplace weakness everywhere;" but these words do not mean that we bear the Council ill-will, or have any desire to frustrate their plans now that the hall has been decided upon as the way to celebrate the centenary.

We may here mention that the building committee appointed to superintend the erection of the hall and to collect subscrip-

tions consists of Baron Schröder, chairman; Sir Trevor Lawrence, Bart., Messrs. J. Gurney Fowler, H. B. May, Martin R. Smith, A. W. Sutton, and H. J. Veitch, with the Rev. W. Wilks as secretary.

The appeal committee is composed of Mr. J. Gurney Fowler, chairman; Baron Schröder, Mr. H. J. Veitch, Mr. H. B. May, and Mr. G. J. Ingram, secretary.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

December 2.—National Chrysanthemum Society's exhibition at the Royal Aquarium (three days); National Chrysanthemum Society's floral committee meeting; National Amateur Gardeners' Association meets.

December 6.—Meeting of the Société Française d'Horticulture de Londres.

December 9.—Royal Horticultural Society's meeting, Drill Hall, Buckingham Gate.

December 11.—National Rose Society's annual general meeting and dinner, Hotel Windsor.

**Royal Horticultural Society.**—The last meeting of the above society this year will be held on Tuesday, December 9, in the Drill Hall, Buckingham Gate, Westminster, 1—4 p.m. An election of new Fellows will take place at three o'clock. At a general meeting held on Tuesday, the 18th inst., forty-four new Fellows were elected, amongst them being the Right Hon. Lord Hastings, the Right Hon. Lady Tweedmouth, Major F. G. Parsons, Major H. Terry, and Captain Hincks, making a total of 1,089 elected since the beginning of the present year.

**The proposed Horticultural Hall.** I do not wish to discuss the plans and elevations of the proposed hall in Vincent Square, because it is always difficult for a layman to criticise another's professional work; but I do not like the view of the hall as it looks on to Bell Street. Whatever may be its appearance when erected, on paper the elevation is singularly bald and even ugly. No doubt it will be pleaded that ornamentation costs money, but the design, apart from ornamentation, seems very poor. The heavy iron lattice girders supporting the hall roof seem to be ugly and quite uncalled for. Surely an architect accustomed to the erection of glass houses could have done far better. Why not copy the splendid light graceful roof of the old conservatory at South Kensington. The setting back of the frontage of the office is, I anticipate, compulsory; but I agree that the railings in front are needless, and may well be dispensed with. Generally, the windows, especially the lower ones, are too short, and give to the building too much the appearance of a warehouse. If some sort of porch or portico could be erected over the Bell Street or side entrance the appearance of the hall would be greatly improved. With respect to the superficial area of the hall, as compared with that of the James Street Drill Hall, the figures given with the plans issued to the Fellows show that the area of the new hall will be 10,650 square feet, and the annexes each of 1,128 feet area, added, will make a total of 12,906, or very nearly 13,000 superficial

feet. The Drill Hall has an area of about 7,000 feet, so that the new hall and adjuncts will furnish space fully three-fourths more than the Drill Hall now does. That is a great gain. If, as seems the purpose, the committees are to sit elsewhere, then the available space for staging will be practically double the existing show space. It does not follow that the new hall could accommodate the Temple, Rose, or Chrysanthemum Shows, and probably never will be required to do so; but for all ordinary purposes it will be an immense advance over the existing one.—A. DEAN.

**Berkshire school gardens.** In March of the current year school gardens were established in a number of villages in Berkshire, and, despite a rather unfavourable year from a weather point of view, these have all proved a signal success. There was a keen competition for the prizes offered for the best gardens by the technical education committee of the Berks County Council. The judge's ruling resulted in the first prize going to Aldermaston, the second to Ardington, and the third to Faringdon. Mr. Keyser kindly entertained the boys of Aldermaston to tea on the evening of the 17th inst., when the prizes were presented by Mrs. Keyser. Each of the prize-winners was greeted with a few cheery words of welcome and encouragement. Both Mr. and Mrs. Keyser take the greatest interest in the movement, which, assisted by such practical encouragement, bids fair to develop considerably in the near future.

**National Dahlia Society.**—The annual meeting will take place at the Hotel Windsor on December 16. The exhibition next year will be held on September 1 and 2, in the Drill Hall, Westminster. There will be a conference on the judging of Cactus Dahlias on the afternoon of the first day. Lord Ilchester has kindly consented to become a patron of the society.

**Plums in November and December.**—In the northern portion of the kingdom there is no difficulty whatever in having late Plums, and I refer to both cooking and dessert varieties. I will note the value of the dessert first, and though the variety is an old one it is most valuable. This is Coe's Golden Drop, and gathered late from an east or north wall the fruits stored in a cool drawer or on shelves keep sound well into the season named. Doubtless the best system to secure the fruits as late as possible is to allow them to hang on the trees into November if the season is mild. Of course this refers to the north, but even in the south the same advice holds good as regards late gathering and cool storage. A new Plum exhibited recently by Mr. Messenger is small but sweeter and richer than Coe's: it will, I think, prove a most valuable Plum for use at this season. The cooking Plum referred to is the Wyedale, and though as regards quality it cannot be compared to the first-named varieties, as a cooking fruit in November it is most profitable. It hangs on the trees till November, and given cool storage keeps well a month later. It is a very hardy variety, and invaluable for growers where fruits in variety are required as late as possible. In addition, the tree makes a free growth and rarely fails to crop. Owing to its late flowering it bears most freely as a standard form, and is not particular as to soil or locality.—A. C. N.

**Japanese Iris failing.**—I think that the non-success of Japanese Iris mentioned by Lady Gordon-Lennox in those interesting "Winter Schemes for Summer Colouring," reproduced from *Country Life*, can be summed up in "want of powerful sunshine." Our climate here in South Devon seems to match mid-Japan, where Iris Kämpferi seems to be most cultivated. From the time the foliage first starts into strong growth till it is beginning to wither we get, in an average year, four months uninterrupted sunshine, powerful enough to ripen the fruits of Euonymus japonicus, Sweet Bay, Magnolia, Camellia, and Cherry Laurel. The water gets so warm that the gold fish lie panting on the surface (they are as hardy here as their cousins the pond carp, and are always unprotected in the winter); even to walk across turf at midday makes the foot hot through the sole of the shoe.

I have felt the surface of the soil when it was warmer than the bare palm of the hand cared for. Given enough water at the roots by irrigation is it to be wondered at that we get flowers 9 inches across, and that the clumps are as thriving as German Iris? I really believe that, speaking generally, all Japanese plants dislike lime. Given perfect conditions they may put up with it, but that is about all; the difference in Bamboos shows this. My soil totally lacks both lime and moisture, yet the Bamboos flourish like Pampas Grass. Two years following, *Arundinaria Simoni variegata* has flowered freely, last year setting good seed. This year has been too cold to ripen it. I think no amount of good cultivation will make these thrive in the pale northern sunshine. They must have much moisture, and this, of necessity, is cold. It is like the Cushion Irises here. These are really at home and steadily increase, without any more care than Iris stylosa gets, which is—none. A plant like *Gerbera Jamesoni* can be managed in a trying climate, as it only wants one thing—viz., heat; but Iris Kämpferi wants this and warm mud—an almost impossible thing in the north. They flower the first year, because "needs must," the future flower being set under Japanese sky.—A. BAYLDON, *Darlish, Devon*.

#### Fruit at Cambridge autumn show.

The fruit at the recent autumn show of the Cambridge Horticultural Society was so fine in colour and quality that it deserves more than passing notice on account of the great strides that have been made in the Eastern Counties during the last few years. Though the very fine exhibit of Mr. G. Woodward was absent this season, owing to the hailstorm in September, which we are all grieved about, there were some very fine local exhibits at this show, and certain varieties were very conspicuous. The many dishes of Peasgood's Nonsuch were remarkable for their finish. The same remark applies to Lane's Prince Albert: the fruits were beautifully coloured, more like highly coloured Cellini Pippin than anything else. In all the fruit classes there was a strong competition, and scarcely a weak dish. Newton Wonder and others were splendid, and some half-bushel baskets of Cox's Orange and King of the Pippins were the finest lot I have seen staged: the latter were remarkable for their perfect shape and colour. The Pear and Grape classes were crowded with really first-rate fruit, the difficulty being to pick out defects. It is quite refreshing to see such grand fruit staged.—G. WYTHES.

**Hampshire County Council Farm School.**—This school, which is at Basing, about two miles from Basingstoke Station, has just issued a most comprehensive syllabus. Instruction is given in agriculture, horticulture, elementary physics, chemistry, plant physiology, weather observations, poultry, bee keeping, dairying, &c. Students are accommodated in the farmhouse and hostel. Mr. D. J. Cowan is director of technical education, Mr. J. C. Newsham is head master, and from him a prospectus and other details may be had.

**November Roses.**—The Rose garden at Madresfield Court presented a wonderful sight on the 20th inst., so great was the profusion of bloom. Three varieties completely outshone all the rest, these being Grand Due Adolphe de Luxembourg, G. Nabonnand, and Perle des Rouges. I shall not easily forget the exquisite effect produced by the first-named, with its rich dual colouring and shell-shaped petals. Attention has frequently been drawn to it, and also to the fact that the National Rose Society have completely ignored it in their list of the best twenty-four bedding Roses. Many of your readers will probably not dissent from me if I place it amongst the best twelve for bedding purposes. Perle des Rouges is certainly another Rose which should be included in this list of bedding varieties, and I am glad that attention was recently drawn to it by Messrs. Buinyard.—A. GOODWIN.

**Galtonia candicans.**—With reference to the illustration of Galtonia candicans in our last issue, Mrs. Clara Myers writes from Dunningwell, Millom, *via* Carnforth: "I am very glad you were able to print the photograph of Galtonia candicans

I sent you the other day. We planted the bulbs at the same time as the Gladiolus corms were put in, and they lasted in flower several weeks, coming in very useful for our many harvest thanksgiving services in September and October. The bulbs will be lifted and stored till next spring for fear of severe frost, though I believe many gardeners leave them always in the ground."

#### Nerine Fothergilli and Canarina campanulata.

Ten years ago I purchased a single medium-sized bulb of this Nerine, and from it have now accumulated a stock of over sixty bulbs, besides having given away some twenty or thirty to friends. But until this autumn I have never had a single flower, nor have my friends been more successful. I was delighted, therefore, when at last four bulbs sent up their spikes and bloomed gloriously. I had begun to despair of success, though I was aware that it was by no means an easy matter to "do" these Nelines well; now, however, having at last broken the spell, I hope for still better results in future. Briefly speaking, the amended treatment has consisted in thoroughly well "baking" the bulbs in their pots on the hottest available shelf in the greenhouse all the summer, and I believe that if we had been favoured with a little more sunshine this year I should have done better. I grow the bulbs three in a 4½-inch pot, carefully repotting them late in the autumn in fresh soil, though I cannot say whether this is the correct treatment or not. They practically live on the greenhouse shelf all the year round. *Apropos* of the baking process, I may mention that my Canarina campanulata, about which I wrote a short note in THE GARDEN some time ago, is again going to flower, though only to the extent of a couple of blooms. It was baked like the Nelines, and would doubtless have stood a lot more "cooking" with advantage. I think it must have started growth prematurely; the stems are now 2 feet high, and the buds likely to open in a few days' time, though it is in quite a cool house.—S. G. R., *Yalding*.

**Grape Alnwick Seedling.**—Very good results have followed the use of this variety as a stock for Black Hamburg and Foster's Seedling by Mr. Edwards, Wentworth House Gardens, Mill Hill, N. I noticed recently that the foliage was unusually vigorous, and on enquiring the cause found it to be attributed to the stock upon which the Vines were grafted. More than one good grower has remarked on the size of berries, as also the vigour of these Vines, far ahead of those on their own roots. This fact is of interest to all Vine growers, for anything that will raise the standard of our Black Hamburg is a step in the right direction.—STEPHEN CASTLE.

**Autumn bloom of Auriculas and Primroses.**—The Primula-like habit of autumn blooms in the Auricula and Polyanthus is seen to be asserting itself this season, probably owing to the cool moist growing weather. Strongly-grown Alpine Auriculas are frequently prone to flower in the autumn, and some are throwing up very strong trusses. Autumn bloom is not always a test of true character, therefore it is best to pinch out the trusses of bloom so that the full strength of the plant may go to the future spring flowers.—R. D.

**Lathyrus latifolius albus grandiflorus.**—This very fine novelty was distributed this year for the first time by Hobbies and Co., Limited (John Green), Norfolk Nurseries, Dereham. It is a very vigorous-growing white Everlasting Pea. The flowers, which are of large size and great substance, are produced in immense spikes. A few days since I was in the nursery at Dereham, and saw in a glass-roofed corridor a plant of this superb variety, which has produced spikes of blossom of startling size. For cutting for floral decorations it is invaluable, but a newly-planted specimen needs two seasons to become thoroughly established to enable it to demonstrate its real character. Mr. Green stated that he had secured a rose-coloured variety of equal size and quality to the white, and which it is anticipated will form an admirable companion to it; but as the stock is very limited it cannot be distributed for a year or two.—R. D.

**A note from Finland.**—On page 305 of THE GARDEN a correspondent says he picked a Strawberry weighing 1½ oz. I think this is nothing remarkable, as last summer I picked here, in our unfavourable climate, a Royal Sovereign Strawberry that weighed fully 62 gr., i.e., approximately 2 oz. (1oz.=31·103gr.). My plants were not given special cultivation, neither were the fruits thinned out. It would be very interesting to hear from other Strawberry cultivators upon this subject.—C. A. COLLIN, *Villa Turvala, Kotka, Finland*, November 9.

**Humea elegans poisonous.**—In the *Lancet* Dr. Hearnden reports that the contact by rubbing of the different parts of *Humea elegans* upon the skin causes severe and prolonged itching, often followed by vesicular eruptions or by inflammation. No doubt the notoriety of *Primula obconica*, with which analogous experiments were made between 1894 and 1896, will be remembered. The phenomena of irritation appear to be the same. We are acquainted with gardeners who cultivate *Humea elegans* as well as *Primula obconica*, and yet we have never seen their skins injured by contact with these plants. Nevertheless, the cases of poisoning mentioned are real, and the testimony of the sufferers is undeniable. It must, therefore, *a priori*, be inferred that the touch of *Humea elegans*, like that of *Primula obconica*, is to be feared by those who are predisposed to skin diseases.—*Le Jardin*.

**Miniature Chrysanthemums.**—During the first fortnight of April cuttings having at their extremity a crown bud are selected. These are placed in small pots filled with soil which has been prepared during the winter, to which one-third of white sand is added. The cuttings are placed on an old hot-bed and kept under glass until they strike root, when they are repotted into larger pots. These tiny plants, bearing, in proportion to their size, enormously large flowers, are of great use for the adornment of flower-stands, &c. The organ of the Société Centrale d'Horticulture du Nord, which mentions this process, adds that Chrysanthemums so remarkable for their original flowering lend themselves to any method of culture.—*Bulletin d'Arboriculture*.

**Apple Coronation.**—This is a welcome addition to the list of first-rate dessert Apples, and well merited the distinction of an award of merit made by the fruit committee of the Royal Horticultural Society on October 21 last. The tree is of compact habit and of medium growth; the fruit is fairly large, and may be described as flattish round. At first the skin is green, changing as the fruit matures to a pale yellow on the shaded side, while that exposed to the sun becomes mottled and streaked with red as the fruit ripens; eye open, and set rather deeply in a round depression; stalk straight and very slender, measuring three-quarters of an inch to an inch in length; this is set in a smooth, rather deep cavity. For table use from November to Christmas there should be a good future for this new Apple. It is of first-rate quality and excellent flavour, which reminds one of Cox's Orange Pippin, and is probably accounted for by reason of the fact that this variety was one of the parents. Apple Coronation was raised at Buxted, and was exhibited by Mr. H. C. Prinsep, of Buxted Park Gardens. The entire stock has been acquired by Mr. G. Pyne, Denver's Nurseries, Topsham, Devon, who is sending it out under the name mentioned above.—C. A. H.

**A hint for florists.**—A florist who has a shop at Cologne has had the happy idea of attracting the attention of the passers-by to his show of flowers and plants by the aid of a proceeding as ingenious in itself as it is good for the plants and flowers. This idea he has realised by making a thin stream of water flow from the top and down the inside of his shop window; the water spreads and descends over the whole surface of the glass like an extremely fine sheet. The undulations, ceaselessly changing and constantly renewed, which the sheet of water produces, considerably dim the clearness of the view of the flowers on show inside, but do not prevent one from recognising them and admiring their freshness.

These undulations produce a new and charming effect, which attracts and fixes the attention of flower-lovers, whilst the evaporation, which naturally is considerable on account of the large surface of the glass, keeps the air moist, to the very great benefit of the plants and cut flowers. The installation of this curious process is very simple. A perfectly horizontal gutter placed at the top of the glass receives a stream of water, which it pours out along its whole length upon the face of the glass. A similar gutter placed at the bottom receives the water, and in its turn empties it into a waste-pipe. The fixing of the apparatus costs but little, and the loss of water is very small. There may perhaps be an idea in this which may be useful to some florist—at any rate we have thought it interesting to point out its ingenuity.—*Revue Horticole*.

**Saxifraga Fortunei**, perhaps because it blooms at a time when flowers are few and far between, always seems to me to be the equal, if not the superior, of any of the family. I have just cut from one small plant a lovely spray of its prettily shaped flowers. I find it quite hardy provided it is planted in a shady moist spot. I have the shade in a north border, and so give the necessary moisture; I bury some large smooth stones round it, which seem to keep the desired condition about its roots. Some years ago there was a fine illustration of it in THE GARDEN, which induced me to acquire it. This shows well another handsome feature, viz., the high colour taken on by the stems and leaf-stalks.—T. J. WEAVER, Thirlwood.

**Astroemeria aurea.**—A good form of this, or of *A. aurantiaca*, which latter name distinguishes the deeper-coloured flower, is a most desirable plant. It grows freely with me in an ordinary border of deep soil. It is best planted in spring, placing the fleshy roots some 9 inches below the surface. It may not bloom the first year, unless strong clumps are procured, but after it has once settled down no plant blooms with more certainty. All it requires is a stake or two round the clump to keep it from being blown about. The heads of bright flowers are fine for cutting, and last well in water. I find self-sown seedlings bloom the second year. But to form new clumps I save a few seeds every autumn, sowing them at once in a pot and keeping them moist all the winter in a greenhouse. In the spring the seedlings come up freely; then I plant them bodily out once for all.—T. J. WEAVER, Thirlwood.

**Malmaison Carnations.**—I observe in your issue of the 15th inst., in acknowledging some blooms of Malmaison Carnations for the Editor's table from Lady Tweedmouth, Guisachan, Beauly, N.B., you mention that her ladyship writes, in an accompanying note, that "the plants at present are one mass of bloom, and are likely to continue for some time to come." It is, I think, rather unusual to have Malmaison Carnations in bloom in quantity at this season, and I am sure it would be interesting to many of your readers if Lady Tweedmouth or her gardener would kindly give a few notes as to the method of culture adopted to have Malmaison Carnations in bloom at this time. These lovely Carnations are not grown so much in Scotland as in England, as they are usually in flower during the months of the London season, and are almost over by the beginning of August, when the Scotch season begins. If they could be depended on to bloom during October and November, I for one would be glad to give more space and attention to them, as they would be most useful for house decoration when outdoor flowers are scarce.—D. M., Scotland.

**Leonotis dubia.**—Between three and four years ago seeds of this plant were sent to Kew by Mr. Mahon from British Central Africa, and it has flowered during late autumn and early winter each year since. In general appearance it bears a close resemblance to a *Salvia*, being of the same semi-woody, semi-herbaceous nature, while the foliage and flowers are also *Salvia*-like. The leaves are thin in texture and ovate, the larger ones being 4 inches to 3 inches long. The flowers are 1½ inches long, of a tawny-orange colour, and borne in dense whorls usually from alternate nodes on the upper

part of each branch. As a rule good inflorescences contain about one hundred flowers, which when fully expanded have the appearance of a tawny-coloured ball. When grown in pots it requires much the same treatment as that given to *Salvia splendens*, stopping the plants frequently while young. When planted out it makes a much larger plant than when grown in a pot, a plant which was grown in a border in the Mexican house two years ago having attained a height of 8 feet, with a diameter of from 4 feet to 5 feet. Where variety in the greenhouse is wanted a few specimens of this curious and interesting subject would be serviceable—W. D.

**Grape Black Alicante.**—It is interesting to learn that in Scotland this fine late Grape is so difficult to grow, whilst in the south it is the very best amateur's late Grape, because so easy of culture. Mr. Owen Thomas has made it clear that to market growers it is not only an easy Grape, but is most profitable. The amateur is not at all a talented Grape grower, as the market grower usually is, but in any case he often does Alicante very well. Not only has it a good constitution, but it sets its flowers freely, and ragged bunches are rarely seen. One evidence of its easy culture is that really good fruit of it can be purchased at from 9d. to 1s. per lb. retail, home grown. This is a poor price for the grower, but he gets compensation because of the great crops produced. Amateur growers cannot do better than grow for late purposes Black Hamburg, and for late Alicante. The latter may not be the best flavoured, but on a well-drained border, with ample sunlight and air, the berries are really good and agreeable-eating.—A. DEAN.

## THE FERN GARDEN.

### DECIDUOUS HARDY FERNS.

**F**ERNS which are natives of cold and temperate climates, in which the conditions of the winter are so rigorous that the frondage is practically destroyed, have developed in large measure the same deciduous or leaf-shedding character as is possessed by the majority of trees. Comparatively few, however, have developed the same capacity of throwing off their fronds at a basal joint, and among our native Ferns only one, *Polypodium vulgare*, or the common Polypody, has this faculty, which, moreover, does not show itself at the usual leaf-shedding season, the autumn, but only in the spring, when the new fronds are rising to replace the old, and consequently monopolise the root action. In the other species, which are deciduous, the fronds in October or November, or even earlier in some cases, commence without any obvious reason to lose their fresh green tints and become first yellow and finally brown, shrivelling eventually to feather-weight *debris*, owing to the retraction of their sap and any contained nourishment into the crown or root-stock. To many people who do not understand this provision of Nature for a thorough rest, the change is imputed to bad health, and the final disappearance or death of the fronds is thought to mean the death of the Fern, the result being subsequent neglect, which makes worse the error. It has so frequently happened in our own experience, especially with lady friends to whom we have given some of our seedlings, that their subsequent loss has been owing to a mysterious disease in the autumn, though every care was taken, that we deem a word of warning not to be out of place in this connexion at this season. Losses occur, however, even with those who understand this phenomenon, for where Ferns are grown in pots in conservatories the absence of any obvious plant for some months is all too apt to lead to those pots being placed out of sight in favour of more presentable occupants, the result being that they are forgotten, left altogether unwatered, and thus either perish outright or are greatly weakened by the drought to which they have been unnaturally subjected.

In their natural habitats the sleeping Ferns are saturated through the winter beneath a thick blanket of fallen leaves, and there is no doubt that, as with bulbs, the roots are at work preparing for the spring growth long before the centres of growth show any signs of activity. Hence one essential to the well-being of Ferns is that they be kept moist throughout the winter, and a good plan is either to pack the pots in a frame with cocoanut fibre or to bury them to their edges in the garden, and mulch them well with dead leaves, thus imitating as far as possible the natural conditions of existence in the dormant period. Our native Ferns belong really to three categories, due probably to our comparatively mild winter climate. Thus in the Lady Ferns, Bladder Ferns, Oak and Beech Ferns, Mountain Lastrea, Marsh Fern, and Royal Fern we have a class which, however we may treat them, die down altogether in the autumn. Then we have an intermediate section, represented by the Soft Male Fern and Broad Buckler Fern, which only drop their fronds to the ground, but under shelter retain their greenness. Finally, in the Hard Male Fern, the Spleenworts, the Hart's-tongue, the Shield Ferns, and Blechnum we have thorough evergreens, the fronds of which are retained well into the subsequent season. In making and arranging Fern collections it is therefore well to bear these peculiarities in mind, especially with planted out Ferns, but of course when grown in pots readjustment in the winter is possible, so as to give good effect even in the dead season. The moral of this note is, however, that dying fronds do not necessarily mean dying Ferns at this period of the year, but that due precautions must be taken as regards watering to ensure that sleep does not culminate in death.

CHAS. T. DREVERY, F.L.S., V.M.H.

#### FERNS AT FOOT OF NORTH WALL.

A NORTH wall is very often the cause of great perplexity to gardeners. Often they are at such a loss to know what to plant either upon it, against it, or at the foot of it, that they finally plant nothing at all. Those who have a wall facing north which now is bare may be able to obtain a welcome suggestion from our illustration. Hardy Ferns are sadly neglected in gardens, yet in many positions they are invaluable, and particularly in such an one as is provided by the shelter of a wall facing north. There they enjoy both the shade and moisture which are so essential to their well-being. The Hart's-tongue Fern especially would seem to be at home under such conditions.

#### CERES, CAPE COLONY.

##### THE WHITE WATSONIA, DISA, AND OTHER PLANTS.

CERES is a neighbouring valley to Tulbagh, and no doubt the flora is much the same, but admitted to be not quite so rich, its mountains are more rugged, and there is a large succulent vegetation at Tulbagh. *Disa grandiflora* is plentiful on the sides of the mountain streams, and so no doubt are other species of *Disa* on the dry ground the same as on Table Mountain. Not being as nimble as I was when searching Spain for Daffodils to confirm, or otherwise, the ancient writers on Daffodils, my search was confined to the rocky foothills, but I was assured on excellent authority in the valley that the flora up the mountains was rich. I advise botanical collectors to call upon Mr. Brett, who takes the greatest interest in the flowers of this valley. He is an old resident, and when proprietor of the Ceres Sanatorium entertained many Englishmen of note, Froude the historian amongst others. He has preserved his guest book, and is proud to show it to anyone curious in such matters.

The valley is entered through a narrow pass known as Ceres Road, and in the rocky part of this the botanist would do well to begin his search. I visited Ceres early in September, and was just a month too early; nevertheless, I found many bulbous plants of interest. The farmers here, as at Tulbagh, are all well-to-do. One of them has an ostrich farm. This I visited and had coffee, and found the sons smart, well-educated youths, and very polite. The Oranges here are of excellent quality, and the land was being prepared for extensive Orange growing. The ground is trenched to a depth of some 4 feet, several quarters had been planted, and this work of trenching and planting was intended to be proceeded with as quickly as labour could be commanded. Cape Town and the Transvaal would be the great

markets to begin with, and should these markets be overstocked London would form a third outlet, but that will be some years hence. Ceres is on the main line from Cape Town to the Transvaal. The valley is some fifteen miles in each direction. The Cape rebels were on the watch to get in to rout the loyalists, so that a strong military force was needed to hold the place, and there were many blockhouses scattered about, some of stone and others of galvanised iron. The latter were so constructed that a space was left between the inner and outer wall, which was filled with sand and loop-holed, as it was found that shot could not penetrate the sand. Then there were forts made with sand-bags to protect the soldiers from the bullets of the enemy should they pass over the mountains. The population of the Ceres Valley numbers 800 to 900. Of this number, I was told, 300 were known to be loyal, and when the inhabitants were called to form the town guard only about thirty responded.

##### DISA GRANDIFLORA.

Few of our gardeners at home succeed in growing *Disa grandiflora* successfully. Mr. Ayres, nurseryman, of Cape Town, on one of his visits to England paid a visit to Dr. Wallace at Colchester, and there saw *D. grandiflora* flowering finer than he had ever

FERNS AT FOOT OF WALL FACING NORTH.

seen it on Table Mountain. It was in pans on a shelf close to the glass in an old lean-to house with many broken panes of glass, and Mr. Ayres attributed the success to the free circulation of air and the cool treatment. Such are the conditions that prevail where this plant grows at its high elevation, where snow is common and biting winds prevail, accompanied by showers of hail during the Cape winter. At one time it was thought that Table Mountain had the exclusive monopoly of *Disa grandiflora*. Now it is found on all the mountains in the western part of Cape Colony where there are streams. In such places the plant is found in abundance, and a plentiful supply can be obtained if there is a demand, which at present is small. It is only a question of collectors going further afield for the bulbs. In making the second reservoir on Table Mountain the principal habitat of *D. grandiflora* was destroyed, and the authorities of Cape Town are doing their best to

##### PRESERVE THE NATIVE FLORA OF TABLE MOUNTAIN,

and especially the preservation of the *Disa* and *Nerine*; nevertheless, the annual destruction is great. Sackfuls of *Nerines* are removed by collectors for export to Europe in collections of Cape bulbs. This has gone on merrily

during the military occupation, many officers being commissioned by their friends to send or take home Cape bulbs; such collections are made up from 5s. to £20. Botanists and scientific men are never refused permits to roam about Table Mountain. Formerly anyone could get a permit; now this has been withdrawn. There are still those who risk the chance of being prosecuted. There is an artist who spends every Sunday—rain or no rain—on the mountain. The other Sunday evening I met him on the tramcar with as many Ericas as he could hold between his two arms. I told him he should be sent to prison, but he only laughed, saying, "I break off the flowers, but do not pull up the roots." Still, destruction has been going on for so many years that the flora of Table Mountain, its gorges and slopes, is not so rich as in the days of the good and devoted botanist Mr. Harvey, to whom we are indebted for the conception of that grand work "Flora Capensis," and which is being followed up by the enthusiastic Mr. Bolus.

#### THE WHITE WATSONIA

has been to me a study of some considerable interest, and I now give the result of my researches into its history, as gathered from the man who found the first one. On my way up the coast the steamship Norman put in at Port Elizabeth (Algoa Bay) to discharge cargo. On landing, my first visit was to Mr. Nosworthy, a produce merchant and commission agent, to whom I introduced myself, and as near as possible I offer to the readers of THE GARDEN his account of the finding, &c. "As a boy I was in the employment of Mr. Upjohn, a botanist of Rondebosch, and went out with the coloured boys to collect bulbs for him to ship to Europe, and to cultivate in his garden. At that time Prince Alfred paid a visit to Cape Town, and from thence to Simon's Town drove along with Governor Gray. Along the route triumphal arches were erected, the one at Rondebosch was in the hands of Mr. Upjohn to erect, and along with the coloured boys I was sent out to collect flowers on the slopes of Table Mountain. Going up an old deserted Dutch avenue I saw a white Watsonia, and thought it would look well in the crown which was to form part of the arch. On my return Mr. Upjohn noticing it asked me where I got it. I told him, and he asked me if I thought I could find the bulb. I said I was sure I could, and off I was at once dispatched. On returning, Mr. Upjohn tried to fit the plant with the cut spike, and said they did not fit. I then told him I had cut a piece off the stalk, and was certain I had brought the bulb. 'Then, lad,' said Mr. Upjohn, 'plant the bulb, and if it flowers white I'll give thee ten shillings, and if not will give thee a towse on the head.' The second year it flowered, and with a considerable increase. I got the ten shillings. I had planted the bulb beside a fine specimen of a white Camellia, and Mr. Upjohn asked why I had chosen this spot, and I said white against white. After that I do not know what became of the bulbs, for soon after this I left for Port Elizabeth. At that time Mr. McGibbon was curator of the Botanic Gardens of Cape Town, and he and Mr. Upjohn were great friends, and I suppose he must have given Mr. McGibbon some of the bulbs." When Mr. Chalwin, the present curator, took over the charge of the Botanic Gardens, now the Municipal Gardens, he found some pots of the white Watsonia. Mr. Templeman, formerly seedsman to the Botanic Gardens, had started a business of his own, and asked Mr. Chalwin for a pot of the white Watsonia.

Shortly afterwards there was a great flower

show at Port Elizabeth, and Mr. Templeman exhibited a collection of Cape bulbs. Mr. Wilson being then curator was very kind to Mr. Templeman, and as a recognition for his kindness put his collection at Mr. Wilson's disposal, who answered, "If you can spare a bulb of the white Watsonia I desire no more." "Take them all," said Mr. Templeman, but Mr. Wilson declined to accept more than two bulbs. About this time Lord Brassey called in with his yacht at Port Elizabeth. Seeing the white Watsonia in flower he desired to purchase bulbs, but Mr. Wilson refused to sell, referring him to Mr. Templeman at Cape Town. At first Mr. Templeman refused to sell; but Lord Brassey said he must have some bulbs. "Then," said Mr. Templeman, "you will have to pay a fancy price; I want a pound a bulb." Lord Brassey bought two, and said if the price had been double he would have possessed them. The exact year I failed to find out, but the Harboard of Cape Town thinks it must have been 1894 when Lord Brassey was there in his yacht, this being the earliest sale I have been able to trace. In cultivation the bulb increases rapidly in the Southern Hemisphere, and thus Mr. Wilson soon had a sufficient stock to consign some bulbs to Mr. James O'Brien, who distributed them under the name W. O'Brien.

Mr. Arderne, The Hill, Claremont, was on a shooting excursion at Worcester, and one of his party brought in an armful of Watsonia rosea, amongst which was one with a white flower. The party retraced their steps, and Mr. Arderne was able to match the cut spike with the plant. The bulb he lifted he took home, planted it, and soon had a good many bulbs. These he exchanged with Mr. Sander of St. Albans for Orchids, &c., and under the name W. Ardernei it is known in cultivation. The third find was at Ceres Road. All I could trace about it was from parties who had received bulbs from gardens there. That it is an albino of W. rosea there is no doubt. There should be no difficulty in growing this fine plant in England in pots. Several in a pot would look well in a conservatory or brought forward in a cold frame and planted out early in June. When in growth they enjoy a free supply of water and as much sun as can be given to them. Like the Gladiolus, cut spikes open indoors. This white Watsonia is a great feature in the Municipal Gardens at Cape Town during the month of October and later. Returning to the Rondebosch arch made by Mr. Upjohn, associated with the crown were some Oranges, and over the crown an inscription:

"Take one Orange, then another, six for father, twelve for mother." Governor Gray cut down the crown and secured the Oranges.

PETER BARR, V.M.H.  
Cape Town, South Africa.

## NOTES ON HARDY PLANTS

### A FIELD OF CROCUSES.

**S**UCH an illustration as the accompanying one, of Crocuses growing in a Berkshire park, brings to mind the great possibilities of bulbs naturalised in the wild parts of the garden and pleasure ground. Such things as Crocuses, of course, must be planted in large numbers, close together, and over a fair extent of ground to produce the best results. They seem to thrive particularly well beneath large trees; this our illustration would seem to prove, although we have often mentioned the fact.

### GERANIUM STRIATUM.

THE true Geraniums, generally hardy flowers in our climate, have been rather neglected in many gardens, although they do not deserve to be overlooked by those adding to their flower borders. One old but very pretty and also free-flowering one is *G. striatum*, a South European species, which was known so long ago as 1629. It was Parkinson's "Variable Striped Cranesbill," and, besides other references, was figured in the *Botanical Magazine*, tab. 55. The illustration in the latter work is, however, not so flattering to the flower as it deserves, though in its main

CROCUSES IN A BERKSHIRE PARK.

characters it is well represented. The colouring also slightly exaggerates the brownish spot at the corners of the divisions of the leaves, though this is readily observed in the greater number of the leaves. Be this as it may, the Striped Cranesbill is a very neat plant, with white flowers prettily netted with red veins, and looking quite attractive when seen in a shaded border, which is the position preferred by the plant. It is of rather trailing habit, and would be a good thing for large rock-work or for a border partially shaded with trees, for which position we have not a superfluity of flowering plants. *G. striatum* is not so aggressive in its growth as some of its congeners, and seems to thrive well in any common soil. It comes into bloom in May or June and continues in flower for several months. It was still flowering when this note was written (November 8). S. ARNOTT.

#### ZAUSCHNERIA CALIFORNICA.

REGARDING "S. W. F.'s" remarks upon this lovely plant in THE GARDEN of the 8th inst., I may remark that I think there is every probability that your correspondent has previously had the early-flowering form of this plant, and that the one he procured this year is the later one. The latter has more tomentose leaves. I may say that the earlier *Zauschneria* is still giving a few flowers here; but the other, though there are buds visible this season, as well as in others, has never bloomed, although tried in the warmest positions available. The early one has brighter green foliage, which is, if anything, rather blunter and more rounded than that of the later.

*Carsethorn*, by Dumfries, N.B. S. ARNOTT.

## THE ROCK GARDEN.

### ROCK GARDEN-MAKING.

#### III.—THE BEST STONE TO USE.

THE question of stones is important in the making of rock gardens, and much depends on a good selection. To use two or three different kinds for the same work—as is often done—is, I consider, a huge mistake. There is no reason why rock gardens made of different materials should not occupy different parts of the garden, if

it be sufficiently large. For instance, we may have a limestone rockery in one part, and, say, a granite rockwork in another, but to mix them is not advisable, as it would be unnatural. To my mind the most unsuitable of all kinds of stones for rock building are bits of glaring white spar or other gaudy stones covered with glassy crystals or of a general vitreous appearance. Owners of quarries generally put aside these pieces and usually sell them to would-be rock builders under the name of "fancy rockery." For convenience of easy handling these stones are generally broken up into pieces of almost uniform size, i.e., about 1 foot to 2 feet in length. For a collection of minerals these pretty crystals may be well enough, but they should never be used for rock building, except perhaps when crushed or broken into small fragments to mix with the soil for such alpines as love a gritty medium to grow in. They are the delight of such masons and jobbing gardeners whose ideas of rock building can never advance beyond the pudding-shaped heaps of soil studded all over and at regular intervals with these uniform bits of glaring spar or crystals. Such creations may still find admirers in the shape of amateurs without horticultural knowledge, whose only garden is a tiny plot in front of a small villa. But to people whose taste has been refined by the study of Nature the "loud" appearance of such stones is repulsively vulgar. Why? Because it is unnatural! In Nature we may find such material in the interior of caves or in hidden crevices, but never on the surface. And as we are—or should be—imitating Nature when building artificial rocks, the beauty of our garden must, under all circumstances, depend on its appearing true to Nature, the artistic grouping and blending of rocks and plants, and the picturesque effect as a whole, but never should it depend on the gorgeous colouring or staring crystals of individual stones.

The same objection, though in a less degree, may be raised against stones of a very new appearance. They are, as a rule, too gaudy or too conspicuous to impart to the rockwork that natural appearance which pleases the eye. Sometimes, however, newly-quarried stones show a sombre tint of red or brown, and the new-looking grey, white, or bluish surfaces are visible only where the break occurred during blasting operations. Such stones as a rule are easily managed, for all that is necessary would be to place the new-looking surfaces

inward, i.e., where they might be covered either by soil or other stones, so that only the older looking surfaces would show. This applies more especially to the various kinds of limestone.

Sometimes it happens that the estate on which a rock garden is to be constructed contains one or more quarry pits where stones might be obtained, and in most cases it would be far better to use what can be had on the spot rather than buy expensive material from a distance. If an old disused quarry is available as a site for a rock garden it would be a double advantage, as the old quarry itself might easily be made into a most picturesque rock garden. All that would be necessary would be to conduct the blasting operations in such a manner as to obtain a good lot of boulders. It often happens that these fall naturally into positions far more natural than they would do by any amount of careful fixing, so that many of them might be left where they fell, while others might be so arranged as to give the whole quarry pit the appearance of well broken natural scenery.

Very often such natural advantages as a quarry pit would afford are out of the question, and stones have to be bought and conveyed sometimes a long distance, and for the guidance of those so situated a few general hints as to what to strive for and what to avoid may not be out of place. Remembering always that it is natural scenery which we wish to reproduce in a rock garden, it naturally follows that the stones should look as old as possible. If, therefore, we live near a moor or any other place where old weather-beaten stones are obtainable, such stones should have preference over all others. In all probability they would not only be dark in colour, but would also be covered with natural moss and lichens, and their use in the rock garden would immediately impart to the work a character of natural antiquity altogether unobtainable by means of new stones, which would require exposure for many years before the surfaces would look weather-beaten. The larger the stones the more natural will be the appearance of the work. This is a rough and ready rule, subject, of course, to modifications, according to the extent of the work. For rock gardens on a small scale, say, requiring only from 10 tons to 20 tons of stone, pieces of stone varying from  $\frac{1}{2}$  cwt. to about 20 cwt. would be quite sufficient, but in works on a large scale some of the pieces of stone may weigh

several tons if the necessary appliances for lifting, &c., are available. In every case a load or two of very small stones weighing only a few pounds should always be added, and should if at all possible have the same aged appearance on the surface as the main body of stone selected for the work. This is a most important point. When stones are put together to resemble large blocks of rock there will be many crevices or corners which will have to be made good with both plants and small stones to unite apparently several lumps of stone into one large block, and if the small stones used for that purpose should be newly broken, while the main body has an old-looking surface, the effect is marred considerably.

As to the colour of the stone it has already been hinted that white or conspicuously coloured stone should be avoided. Much must, of course, depend on the nature of the stone obtainable, but the colours which best show up both bright flowers and green leaves are dull red-brown and dark grey.

#### GEOLOGY IN THE ROCK GARDEN.

Since it is impossible to construct a good rock garden without some knowledge of the works of Nature I will briefly touch upon a few points which in this connexion I consider of vital importance. Geologists divide all rocks into two great classes, namely:

(a) *Igneous rocks*, which are devoid of fossils, and show no proper stratification. These, it is assumed, were

A LESSON FROM NATURE: NATURAL GRANITE ROCKS ON ST. MICHAEL'S MOUNT, CORNWALL, THE PROPERTY OF LORD ST. LEVAN.

originally in a more or less liquid state caused by fusion, and were either poured out over the surface of the earth in a molten condition or were consolidated before reaching the surface.

(b) *Sedimentary or stratified rocks.*—These were formed under water, either through the accumulation of the debris from disintegrated previous rocks which the water had sorted into successive layers, or through the secretive power of certain organisms, such as the minute shells or skeletons of small crustacea, &c.

In shape, general distribution, and arrangement both classes differ very widely indeed, and it is absolutely necessary to know at least the rudimentary principles of the natural disposition of these rocks before we can possibly build rocks which should resemble Nature's work. I will, therefore, briefly state the different characters of these two sections as far as they affect the construction of rock gardens.

#### IGNEOUS ROCKS.

It has already been stated that igneous rocks are considered to have been at some period in a molten condition. They usually consist of several minerals mixed together more or less evenly or scattered throughout a more or less vitreous ground mass. Geologists sub-divide the igneous rocks into *plutonic rocks* and *volcanic rocks*. The plutonic rocks are assumed to have been upheaved from the interior of the earth by great heat. During these upheavals the molten masses forced their way through other strata, and when found on the surface they are generally scattered in the wildest profusion. Granite and porphyry are the best examples of plutonic rocks. The second sub-division, i.e., the volcanic rocks, are supposed to be the result of volcanic eruptions during bygone ages; to this latter class belong trap, basalt, greenstone, &c.

Of all igneous rocks the most important for rock building is probably granite. Newly broken in a granite quarry it may not be a desirable material to work with, as there is something cold and unattractive in its even light grey colour which does not lend itself to the making of picturesque scenery; but the case is altogether different when pieces of granite can be obtained, which already have a weather-beaten surface, darkened by ages of exposure and covered with moss and lichen. Such pieces are among the most desirable of all materials for rock building, and on Dartmoor or the moors of Cornwall such boulders may be had in quantity and of all sizes.

Since we have to look to Nature for our teacher it may be well to take a lesson in arranging granite rocks from Nature's own work. The accompanying illustration was prepared from a photograph, which I was allowed to take on St. Michael's Mount, Cornwall, the property of Lord St. Levan. It shows the picturesque beauty and the characteristic disposition of granite rocks towering high above the ground in one place and vanishing abruptly into the ground in another, the rocks forming bold projections and deep recesses sometimes hidden from view by luxuriant vegetation, sometimes just piercing through the carpet of plants, suggesting still bolder and more extended rocks below the surface. The plants in this instance consisted of dense masses of *Armeria maritima* (unfortunately out of bloom when the photograph was taken) and *Silene maritima*.

Stratification does not occur in granite, and setting up artificial rocks with blocks of granite arranged in lines would be absolutely wrong and contrary to Nature; in fact, no rock could be more irregular. Sometimes, it is true, there appear to be lines which do somewhat resemble the strata in sedimentary rocks, but they are merely fissures, caused most probably by contraction during the process of the cooling and consolidating of the originally molten mass.

It will thus be seen that igneous rocks, and granite boulders especially, demand less restriction in their use for the rock garden than stratified rocks, and the rock builder when working with granite boulders has more scope than with most other kinds of stone. Sometimes, when loose stones with an exposed surface cannot be obtained

from a moor, it is possible to obtain them from granite quarries; not newly broken stone—which I consider is quite unsuitable—but stones thrown aside as useless, and which have had several years of exposure. In almost every granite quarry unexpected breakages occur from time to time of stones originally raised with a view of being hewn and chiselled into more or less regular shapes, but which by some means or other were spoiled for the original purpose, and being "too ugly for a builder," were thrown aside. I know quarries which during many years of working have amassed great piles of such stones, which have not only an exposed surface but are covered also with moss or lichen. Such stones would be especially suitable for stepping stones in a bog garden or similar purposes, but also for bold masses of rock-work they are often well adapted.

#### SEDIMENTARY ROCKS.

Totally different from igneous rocks are the sedimentary or stratified rocks, which, as the name implies, were formed under water and were afterwards exposed to view, either by the receding of the water or by upheavals from the interior of the earth. All of them show more or less regular lines or strata. Sometimes these lines are broken up by volcanic action or by igneous rocks in a state of fusion having come in contact with them or forced their way through them. In the latter case the strata are often irregularly twisted or show indistinctly as in some kinds of limestone, slate, &c. Other stratified rocks useful for rock building are various kinds of sandstone, flint, oolite, &c. The stratified rocks also include the so-called *metamorphic rocks*, which have become crystallised, and whose nature has changed owing to contact with igneous rocks in a molten state.

*Limestone* is the most important of all stratified rocks for rock garden-making, and naturally contains more variation, boldness, and picturesqueness than most other stratified rocks. Its colour, too, is generally such as not to be objectionable, even when fresh from the quarry. A very useful kind of *oolitic limestone* of a dark yellow or light brown colour is found near Bath, where blocks of all sizes are often obtainable. Some of these blocks may be seen in the botanic gardens, Victoria Park, Bath, where a great number were used. Some of these stones are perforated naturally by large holes, forming excellent pockets for plants.

*Red sandstone*, especially of the "old red sandstone" formation, also is well adapted for rock building, its rich warm colour contrasting effectively with the verdure of the plants.

When stratified rocks are used for the rock garden, it will, of course, be necessary to imitate the natural strata, and for this purpose it will be well to select mostly flat stones of various sizes. Not only will these be found most useful for building apparently large blocks of rock, but they

A WINTER PICTURE (THE WHITE STEMMED BRAMBLE, *RUBUS BIFLORUS*.)

are also useful for a variety of other purposes, such as bridges across a streamlet, rocky steps, or even for forming narrow crevices below the ground surface, to be specially prepared for choice alpine plants.

The actual way of building such rocks without making them monotonous will be fully described in subsequent chapters.

*Elmside, Exeter.*

F. W. MEYER.

(To be continued.)

## TREES AND SHRUBS.

### RUBUS BIFLORUS.

FOR horticultural purposes the hardy Brambles may be readily divided into three well-defined groups—firstly, those grown for their fruits; secondly, those which are valuable on account of their flowers; and, thirdly, those having coloured stems. In the latter group some ten or a dozen species can be included, the one under notice—which is commonly called the White Stemmed Bramble—being possibly the best known. It is a native of the Temperate Himalaya, and has been known for many years, though it is only recently that it has been cultivated to any great extent. When planted in good rich loam it grows to a height of from 9 feet to 12 feet, the stronger shoots being 1 inch in diameter. The flowers, which are produced during summer, are white and rather inconspicuous. The leaves which are composed of from

three to five leaflets, are fairly large, green above and white beneath. The stems are armed with stout hooked prickles, and are densely covered with a thick glaucous bloom, which, seen in winter after the leaves have fallen, gives the plant a quaint and picturesque appearance, especially when the sun is shining on it, or on a bright moonlight night. After the flowers are over it is a good plan to cut away all the old wood, as is done with Raspberries, the young shoots being much better coloured than the old. For a small garden it is hardly a plant that can be recommended, it is such a rampant grower. For a large garden or park, however, especially if it can be allowed to grow in a semi-wild state, it is distinctly valuable. When growing vigorously in rich soil some shelter from high winds should be given, for as the tops are heavy they are liable to break during a gale. *Rubus biflorus* is easily raised from seeds, and the stems of one year old plants are usually well coloured.

W. DALLIMORE.

#### FLOWERING SHRUBS BY WATERSIDE.

WHEN planting the margin of a lake or stream in the garden the great value of flowering shrubs for this purpose is often overlooked. The charms of water gardening lie hardly less in the selection and arrangement of plants for the margin than of those in the water itself, for

unless the bank is clothed with a suitable collection of plants there will be no reflection of their flowers and foliage, as in different seasons they exhibit their fullest beauty. The delightful effect that the Rhododendron by the waterside produces when in flower is well shown in the accompanying illustration, and there are other hardy flowering shrubs equally as suitable and as beautiful that might with great advantage frequently be planted in a similar position.

H. T.

#### NOTES ON LILIES IN 1902.

**I**NTEREST in the Lily family has not received the stimulus it did in 1901, when the conference at Chiswick drew together so many admirers of this beautiful class of plants, who were not only delighted at the display then afforded, but were also supplied in the autumn, through the Journal of the Royal Horticultural Society, with the numerous and most interesting papers read at the conference. New Lilies, too, have this year been conspicuous by their absence, and throughout the season only one has been given an award by the Royal Horticultural Society. This is

LILUM BROWNII CHLORASTER,  
which was given an award of merit when shown by Messrs. Veitch on September 23. It is by no means a new, though still a scarce, Lily, for it first flowered at Kew in 1891, when it was named as above by Mr. Baker. This Lily was sent by

Dr. Henry in 1889 in the same box as *Lilium Henryi* and also *L. Brownii leucanthum*, a trio of most valuable Lilies. Two of them—*L. Brownii Chloraster* and *L. Henryi*—have in conjunction given us that most interesting hybrid *L. kewense*, which has been illustrated and several times noted in THE GARDEN. Strange to say, it resembles nothing so much as a small spotless flower of *L. auratum*. Of the rarer Lilies, we have made the acquaintance of

L. KELLOGGI.

a pretty Turk's-cap-like flower of a pale lilac tint, spotted with purple. It is a native of California, and, like many species from that district, it is doubtful if it will prove very amenable to cultivation. *Lilium sulphureum* continues to gain ground in popular favour year after year, and it is certainly the most valuable Lily that we have for autumn and early winter-flowering. In reference to this last sentence exception must be taken to those popular kinds such as *L. auratum*, *L. longiflorum*, and *L. speciosum*, the bulbs of which have been kept in a dormant state by means of refrigerators, which, of course, upset all our preconceived notions by flowering at almost any season.

Concerning what may be regarded as the rank and file of the Lily family, the year 1902 has been on the whole by no means a favourable season for them, the cold damp spring and late frosts playing considerable havoc in many cases, while the more robust kinds have been particularly late in expanding their flowers; thus in many cases June was well advanced before such early-flowering kinds as *L. pyrenaicum*, *L. davuricum* or *umbellatum*, and *L. elegans* were at their best. With regard to these species, and also the early summer-flowering

RHODODENDRONS BY WATERSIDE.

kinds, this was of little account, but with *Lilium speciosum*, whose late summer and early autumn display out of doors is usually so valuable, the result was entirely different, for, being a fortnight or more later than usual, the cold autumnal nights and heavy dews prevented the buds from opening properly, hence in many places the display was greatly inferior to what had been reasonably anticipated. This was especially the case with imported bulbs, which flower from ten to fourteen days later than established ones, a fact that is often not sufficiently recognised. Under glass *L. speciosum*, represented by its several different forms, is as valuable as ever for bridging over the period between the summer-flowering plants and the Chrysanthemums, the fact that it is rarely attacked by insect pests being a great point in its favour. Of the

## DIFFERENT LILY DISEASES

that give so much trouble the fungus that attacks *Lilium candidum* has been in many instances unusually prevalent, so much so as in several districts entirely to rob this charming plant of its beauty. I read in THE GARDEN a short time since that the bulbs of this Lily sent from France were a source of great trouble, as they were reeking with disease, and this is also my experience. Another cause is, I think, that it is impossible to get the fact generally recognised that this Lily should at the latest be planted by the end of August, hence large quantities of bulbs are sold two or three months later than this, and to keep them even partially dormant up to then they have been dried in warehouses or so treated that a good deal of their vitality is lost, and they then readily fall a prey to disease. In my opinion a golden rule to be observed in the case of *L. candidum* is if they do well by all means leave the bulbs undisturbed.

*Lilium auratum*, too, has in many places failed again, this year the bulbs in some instances being attacked, while in others what is generally regarded as a kind of sun-stroke has been very fatal. At all events so prone is this Lily to disease that in many districts it is quite useless. Another point very marked within the last few years is that we do not get such good bulbs from Japan as was at one time the case; indeed, judging by the state in which many of them reach here, one is forced to the conclusion that the disease prevails in that country to a considerable extent.

Of *L. longiflorum*, which vies with *L. speciosum* in being the most popular Lily that we have, enormous quantities of splendid bulbs are sent from Japan, but in their case the season would appear to be considerably later than last year, for in 1901 large quantities were disposed of at the London auction rooms on October 7, whereas the first instalment (and that a small one) this year was not till October 27, and after that it was necessary to wait till the 17th and 19th inst.

H. P.

## AYRSHIRE AND EVERGREEN ROSES.

THE graceful habit of growth and wealth of blossom of the Ayrshire and evergreen Roses cannot be better displayed than when clambering over porch and house front, as shown in the accompanying illustration. One could wish their beauty were not so fleeting. Without a doubt the old Félicité Perpétue and its

pretty companion Alice Gray are the best representatives of the two groups, although there are several others, such as Ruba, Bennett's Seedling, Flora, and Myrianthes Renoncule, that are also valuable. I would suggest that a vigorous growing Tea or Noisette Rose be planted wherever practicable to mingle with the summer bloomers, so that the house front and porch be not entirely devoid of bloom in the autumn. What could be more lovely than the ruby foliage and golden blossom of Rêve d'Or or the cheerful red of Longworth Rambler peering out among the white clusters of Félicité Perpétue?

ROSES ALICE GRAY AND FELICITE PERPETUE OVER PORCH.

The Ayrshire and evergreen Roses should be left severely alone as regards pruning, all that is necessary being to thin out a few of the older growths now and then. Do not forget to give them stimulants in the summer, for they prove of inestimable value. It must not be supposed that these pretty Roses have no other uses than for lofty climbing. I love to see them running over a heap of tree stumps or a mound of earth. I am not sure I care to see Roses on a covered pergola, for much of their beauty is lost to view, but for arches or a series of arches no Roses can be more delightful than these.

PHILOMEL.

## KEW NOTES.

## INTERESTING PLANTS IN FLOWER.

## Temperate House.

*ACACIA UROPHYLLA*, *Begonia coccinea*, *Cytisus filipes*, *Podophyllum pleianthum*, and *Rhododendrons* (various Malayan varieties).

## Palm House.

*Acokanthera spectabilis* and *Sterculia mexicana*.

## Orchid Houses.

*Angraecum pertusum*, *Bifrenaria Charlesworthii*, *Bulbophyllum auricomum*, *B. lilacinum*, *B. Pechei*, *B. rufinum*, *Calanthe Veitchii*, *C. vestita* var. *luteo-oculata*, *Catasetum chlorochilum*, *C. christyanum*, *Cattleya labiata* var. *dowiana*, *Cirrho-petalum makoyanum*, *Cymbidium dayanum*, *C. giganteum*, *C. traceyanum*, *Cynorkis lowiana*, *Cypripedium concolor*, *C. fitchianum*, *C. insigne*, *C. insigne* var. *Sanderiae*, *C. leeanum*, *C. Morganiae*, *C. pitcherianum*, *C. Sallieri*, *C. spicerianum*, *C. venustum*, *C. virens*, *Dendrobium aureum*, *Laelia anceps*, *Laelio-Cattleya Decia*, *Listrostachys (Angraecum) pellucidum*, *Lycaste xylophora*, *Masdevallia Chelsoni*, *M. Chimera*, *M. ignea*, *M. nidifica*, *M. wageneriana*, *Maxillaria nigrescens*, *M. rufescens*, *Odontoglossum crispum*, *O. gloriosum*, *Oncidium bracteatum*, *O. carthaginense*, *O. monachicum*, *O. raniferum*, *O. tigrinum*, *O. varicosum*, *Pleurothallis cardiocrepis*, *P. longissima*, *P. velutina*, *Selenipedium calurum*, *S. grande*, and *S. Roezlii*.

## T Range.

*Echmea coelestis*, *Allamanda purpurea*, *Arisaema Wrayi*, *Begonia baageana* and various winter-flowering hybrids, including the new tuberous-rooted varieties *Adonis*, *Ensign*, *John Heal*, *Julius*, *Mrs. Heal*, and *Venus*, also *Gloire de Lorraine* and *Turnford Hall*; *Clerodendron speciosum*, *C. splendens*, *C. umbellatum*, *Clivia Gardoni*, *Hippeastrum aulicum*, *Ipomoea Horsfalliae* var. *Briggsii*, *I. ternata*, *Jacobinia chrysostephana*, *Justicia calycotricha*, *Lindenbergia grandiflora*, *Nerine Manselli*, *Pitcairnia alta*, *P. muscosa*, *Plumbago rosea*, *Spathiphyllum floribundum*, and *S. Minahassae*.

## Succulent House.

*Cotyledon fulgens*.

## Greenhouse.

Among other things the following are conspicuous: *Acacia platyptera*, *Begonia glaucocephala*, *B. Gloire de Lorraine*, *Centropogon lucyanus*, *Cestrum aurantiacum*, *Chrysanthemums* in variety, *Cyclamen*, *Epacris* in variety, *Erica melanthera*, *Hidalgoa Wercklei*, *Jasminum grandiflorum*, *Luculia gratissima*, *Peristrophe speciosa*, and various *Primulas*.

## Outdoors.

*Escallonia exoniensis*, *Galanthus nivalis* var. *octoberensis*, and *Iris unguicularis (stylosa)* are conspicuous.

## IN A KENTISH GARDEN.—1902.

Now that the much-abused year 1902 is drawing to a close, and we gardeners have almost ceased to care what further disagreeable surprises it may have in store for us, I

venture to send a few notes on the behaviour of my shrubs and plants, under what may, I think, be considered most trying conditions up to the middle of October.

The winter was certainly a mild one, taken as a whole, though we had a very sharp spell of frost in February, culminating in the fall of the thermometer to 5° Fahr. on the 16th, which undoubtedly did considerable damage, while the drought in April and general want of genial weather throughout the spring did not help matters. Then came the memorable and malignant frost of May 14, the thermometer here falling to 22°, and, by way of a climax to our troubles, we had a most terrible hailstorm in this district on September 10, the effect of which, especially on the Hops and fruit crops, was indeed disastrous, gardens suffering also most cruelly. But there is always the proverbial silver lining to the darkest cloud, and as far as the garden is concerned it is comforting to record that never were Roses as glorious as they have been this year. I say "have been," but even now (October 20) there are many lovely blooms on the plants and countless buds, needing only a little more sunshine to develop them. The first blooms, though a bit late, were truly magnificent, hardly any trees here (dwarfs on seedling Briar and on their own roots) failing to contribute to the feast of colour and sweetness, many of the individual flowers being of superb form and brilliance.

Among my own Roses I consider the best to have been La France (finer than ever I saw it before), Caroline Testout, Mrs. Sharman Crawford, George Nabonnand, Viscountess Folkestone, Clara Watson, White Maman Cochet, Beauté Inéstante (better than usual), Mme. Pernet Ducher, Mrs. W. J. Grant, Mme. Falcot, Anna Olivier, and climbing Perle des Jardins (on wall). L'Ideale was very fine on a wall, but Fortune's Yellow, which last year had about 500 blooms, produced only twenty or so this season. Altogether the Roses have, as it were, saved the situation, and instead of converting one of my small beds into another bit of rockery (as I had thought of doing) I shall have to reverse the process perhaps and go in for more Roses.

Spring bulbs were decidedly good all round. I will mention no names except Anemone blanda, which grows like a weed here in my stiff loam in all its lovely shades, and which, to my mind, is not sufficiently grown by lovers of spring flowers. The last Narcissus flower had hardly withered, however, when the frost of May 14 came upon us and worked such fearful mischief. The orchards in this district suffered cruelly, the Cherry crop being practically destroyed. Last year (a phenomenal one certainly for Cherries) we picked about 400 bushels in my small orchard; this year we managed with difficulty to gather 3 bushels! Pears were nearly all ruined, and the Apple crop reduced to about one-third of its normal amount. Bush fruits and Strawberries came out of the ordeal better, the latter quite recovering themselves and producing a good crop.

The damage done by this frost, in conjunction with the severe one in February, to my garden was considerable, though the list of things killed outright may seem to disprove this statement. Ceanothus Gloire de Versailles, White Tree Lupins (nearly all), Salvia patens (left out for four years previously with impunity), Ostrowskia magnifica, and a few Tea Roses were absolutely wiped out, but I may be wrong in attributing the loss of the Ostrowskia to the severe weather, as it was by no means doing well before.

Among the severely wounded, but since recovered, were the common Myrtle, Oleariastellulata (*Eurybia gunniana*), Arundinaria Falconeri (harder hit than usual). *Phyllostachys mitis*, *P. sulphurea*, and *P. Illemonis* were quite untouched), and *Dracena australis*. The Walnut trees all dropped their first crop of leaves (and of course their fruit) and took a long time to reclothe themselves. Hardy Ferns were browned or "burnt" a good deal, but soon got over it. *Olearia Haasti* was uninjured, but *Solanum jasminoides* was much affected, and has since refused to flower, while *Berberis nepalensis*, Yellow Tree Lupins, and one or two white ones were badly crippled.

In the case of *Dracena australis* an interesting recovery has taken place. I have grown several out of doors for some years, and two of them had done exceedingly well in semi-shade, and were of considerable height. I also put out two more small ones last autumn. After the frost the larger of the old ones, which got a trifle browned, soon went ahead again, but I fancied the rest were all dead. Not so, however, for the small ones have both sent up suckers from their roots, while the other old one has not only done this, but has thrown out a perfect chaplet or circle of healthy shoots round the trunk 4 feet from the ground. The effect of this, with the dead stem above looking wonderfully like a "tip-tilted" elephant's trunk, is very peculiar. I hope the new crown may eventually form a good leafy head.

I fear my two New Zealand pink Brooms (*Notospartium Carmichaeliae*) are mortally wounded—they are alive, but that is all I can say. Other Brooms did well, especially *Genista virgata*, every spray of which was gloriously laden with its golden burden; it is, indeed, a lovely thing, and apparently quite hardy. *Carpenteria californica* (against a wall) was not damaged, but it did not flower so well as last year. *Lilacs* flowered well; but the Laburnums were a complete failure with me. Rhododendrons were better than usual in spite of the April drought. My *Calochortus* bloomed magnificently, both Spanish and English Iris were very fine; the various forms of *Iris germanica* not so good. Herbaceous Phloxes were late and rather weak, the only exception being Avalanche, a splendid success; it was far and away the best white of the lot. Delphiniums were good, and by cutting down the old flower-stems I have prolonged the blooming period until the present time, when I have many fine spikes still going. This may be a reprehensible practice and likely to weaken the plants, but surely it is worth the risk when seedlings are so easily raised to fill blanks.

Generally speaking bedding plants and half-hardy things put out for the summer have done well, though *Browallia elata grandiflora* was a miserable failure. Sweet Peas were better than I ever had them before, and are still flowering, though rather feebly. I regret to say the Lilies were, with one or two exceptions, very poor and seraggy. *L. candidum* threw up a good few spikes, but with me the flowers were small both in number and size. At one time I feared the foul disease was among them, as the foliage decayed and turned brown, but the blooms came to maturity, so I trust it was only the effect of the weather, or it may be that the exceptionally strong blooming of the previous summer had somewhat exhausted the bulbs. *L. szovitzianum* was again very fine, one spike having twenty-two flowers. *L. excelsum*, *L. speciosum* *Melpomene*, *L. Grayi*, and *L. longiflorum insulare* (Wallace's new form) were also very good, the latter being

most attractive with its glossy dark foliage. *L. giganteum*, the only bulb I possessed, flowered fairly well, though the spike was barely 5 feet high. The stem is still green and is crowned with a group of promising-looking seed-pods, but I take it, from what I have recently seen in print in the gardening papers, that no seed is ever produced in this country. I shall presently cut the top of the stem off and place it in water or damp sand in the greenhouse and hope against hope. I do not think the seed can possibly ripen in its present position.

*L. rubellum* was about the same as last year, decidedly good, but with a maximum of two flowers to a stem. I wonder if this is the rule with the species. Without going into wearisome detail I may say that the rest of my Lilies were conspicuous failures, with the exception of my old and valued friend *L. Parryi*, who came up smiling as if to show the others how it could be done. In all he decorated himself with twenty-one spikes (assorted sizes) ornamented with 159 flowers; not a good average, but a commendable total considering the fact that only six bulbs were originally planted. The best spike consisted of only seventeen blooms, not to be compared with my thirty-nine of past years, but the grand total is the best I have ever had, and the effect of such a group was very striking.

It may be worthy of record that two years ago I planted a bulb of *L. sulphureum* (*wallachianum superbum*) and also another bulb this year. The older one made no show last year, but this summer sent up two weak and flowerless, but healthy, spikes, while the new one quite lately has developed a fairly promising spike, which cannot possibly come to any good now. Two bulbs of *Alexandræ* carefully planted in early spring never came up at all; but I am getting used to the vagaries of these capricious things.

A few words as to the present state of the garden and I will make an end of this long rigmarole. The mild wet weather during the autumn has undoubtedly suited the constitution of many late-flowering plants, though it has by no means agreed with that of *Zauschneria* and *Plumbago Larpetæ*; these are very poor here. On the other hand, *Salvia splendens Bruanti* is a fiery blaze of scarlet; hardy Heaths, notably the *Menziesias*, are still in fine bloom; the purple-topped Clary (*Salvia Horminum*) is yet a mass of welcome colour; while Stoeks, Dahlias, Michaelmas Daisies, Cannas, Begonias, and Marguerites are at their best. How long this desirable state of things will last is uncertain; the first sharp frost will pretty well do for them all.

The rain and the wind have utterly spoilt the *Crocus speciosus*, *Colchicums*, and the few blooms of *Sternbergia* that descended to appear, but hardy *Cyclamens* are doing grandly, the autumn species flowering nicely, and the others promising well for the early spring. *Gladioli* have not done well; I left nearly all of them out through the winter. Among those that have succeeded I may mention a very handsome dark violet one, Baron J. Hulot; this was planted in the spring. Another of the so-called "blue" forms, the name of which I do not know, is of a pale mauve colour and rather pretty, but not to be mentioned in the same breath as the Baron.

And now, though I can hardly say I have exhausted my subject, I will conclude by expressing the fervent wish that we may never again have to pass through such a trying and unkindly gardening season as that of 1902.

Yalding, Kent, October 20. S. G. REID.

**SUCCESSFUL GRAPE GROWING**

By this post I send you a photograph for reproduction in the columns of THE GARDEN should you think it suitable for that purpose. It is a view of a remarkably fine crop of Grapes grown this year in a private viney at Marpool, Exmouth ; it was taken before any Grapes had been gathered. The house consists of seven separate Vine stocks, carrying on the average two rods apiece, and bearing altogether 281 large well-grown bunches of Grapes.

Thus each Vine on the average produced 40 bunches and each rod 20. It should be added that five of the Vines are Black Hamburg, one is an uncertain variety of Black Hamburg, and the other is an Alnwick Seedling. All have their roots in an outside border. Three of the Black Hamburgs are believed to be at least 70 years of age, and have the merit of being uniformly the best croppers in the house. The other four Vines, inclusive of the Alnwick Seedling, are to my knowledge more than 20 years old.

*Marpool, near Exmouth.* J. P. PHEAR.

**CORRESPONDENCE.**

(*The Editor is not responsible for the opinions expressed by correspondents.*)

**PEAR DIRECTEUR HARDY.**

[To the EDITOR OF "THE GARDEN."]

**S**IR,—The note on page 312 by the Rev. W. Wilks was most opportune, as it will bring to the notice of fruit growers and those who like really good Pears this excellent variety. My reason for sending this note is that I have Pear Directeur Hardy both as bush and cordon trees ; the latter may not be the best test as to its fruiting qualities, but there can be question that cordon fruits are valuable for their size, colour, and appearance. Grown as a bush Directeur Hardy promises well,

and, what is better, I thought the fruits grown thus, though smaller, were of finer flavour than the larger ones. This variety is given as a November fruit in catalogues, but ours were ready early in October, and the quality was very fine indeed. I think Directeur Hardy will prove a first-rate cropper, as the trees, though small, are very free, and the wood made is well furnished with fruit buds. Of course my note refers to this part of the country (Syon), but it should thrive well on a wall in the northern counties.

G. WYTHES.

**CINERARIA STELLATA IN THE FLOWER GARDEN.**

[To the EDITOR OF "THE GARDEN."]

SIR,—There can be little doubt that this type of Cineraria will, in the near future, play an important part in the flower garden for autumn display. I gave the beautiful variety called Sky-blue, sent out by Vilmorin, a trial this year, and at the present moment it is one mass of the most lovely blue one could wish for. It was quite an experiment. But I observed that the stellata type comes into flower much earlier than the large-flowered kinds, and it occurred to me that with careful management it may be induced to flower early in the autumn, which idea has been fulfilled. Of course early sowing is essential. I sowed the seed from which the plants now in flower were raised last Christmas. They were kept steadily moving and early pricked off into boxes, keeping them quite cool during the winter ; in the spring they were again given a little more room, transferring them to larger boxes, and from these they were planted out into beds in June. The beds are shaded by trees and shrubs, and it is naturally a cool place—both soil and position—and this of course just suits these plants.

It would be unwise to plant Cinerarias in full sun; even in the present situation it was found necessary to place a few boughs between them during those few warm days we experienced in July. Of course I do not overlook the fact that the past season has been one admirably suited to such plants. But I also see a future for these plants in shady parts

of the garden, and how well they will associate with Michaelmas Daisies, Chrysanthemums, Marquerites, and autumn-flowering plants. I believe there is no question about success if the seed is sown early enough and proper places are chosen for the plants. What a fine autumn bed may be created by planting these with Aster sinensis (the single mauve or pale blue annual Aster), Aster Amellus bessarabicus, A. Orion, or indeed any of the dwarf Aster.

I trust that this note will be the means of inducing gardeners to give Cineraria stellata a trial in the open. I find they like really rich soil. Another matter worth mentioning is that these plants lift splendidly. Some of the later ones I lifted and potted : they are now large spreading dwarf bushes and masses of lovely bloom.

*Cirencester.*

T. ARNOLD.

**GRAPES—NEW AND OLD.**

[To the EDITOR OF "THE GARDEN."]

SIR,—While there can be no doubt that Lady Hastings is a very good black Grape, it was a matter for surprise that the originator of the variety—Mr. Shingler—should have mated it to such an inferior variety as Gros Colman in the hope of getting from the cross something good. The seedling Melton Constable, obtained from these parents and shown to the fruit committee the other day at the Drill Hall, was almost in appearance and taste the same as Gros Maroc, one of the noblest-looking Grapes we have, yet in flavour most worthless. With Grapes of such noble appearance as we now have, generally easy to grow and fine in bunch and berry, it is to be deplored that efforts in seedling raising should not be more devoted to the production of flavour than is apparently at present the case. Better results might have been looked for by mating Lady Hastings with Madresfield Court or Mrs. Pince, especially as Lady Hastings, having come as a sport from Muscat Hamburg, high-class quality should be her dominating feature. Very recently, when two named Grapes were shown from one grower at the Drill Hall, one, an old variety, was much the better flavoured, although least ripe. Happily, few new Grapes are put into commerce or come to the Drill Hall, and it is well that it should be so whilst growers make appearance and size of berry their primary aim rather than first-class flavour. Our very best-flavoured and most admired of table Grapes are all old—Black Hamburg, Madresfield Court, Mrs. Pince, Muscat Hamburg, and Muscat of Alexandria. Such varieties as Gros Colman, Black Alicante, and Lady Downe's are popular because they are easily grown, great croppers, keep late, and can be sold very cheaply in the market, but they have no place amongst best flavoured Grapes.

It may appear to be a grave indictment of exhibitions, but it does seem as if these, by specially encouraging the culture of large-bunched Grapes, even if of low quality, put a premium on the culture of inferior varieties. At the great show at Shrewsbury it was not pleasant to find such inferior varieties as Alicante, Alnwick Seedling, and Gros Maroc, all certainly finely berried and finished, though generally the bunches were ugly, placed before collections which included Black Hamburg, Madresfield Court, Mrs. Pince, Muscat Hamburg, &c. But, so long as at exhibitions appearance is almost everything in Grapes, and quality or flavour is of minor importance, so long will this thing be. Grape raising is yet of far too haphazard a kind. Some seedlings that have names given them are probably mere natural productions. Some are probably artificially produced, yet with no definite aim or purpose. Is it not possible for someone having youth and opportunities on their side—such as

AN AMATEUR'S VINEY. (From a photograph kindly sent by Sir J. P. Phear.)

Messrs. Rivers to do for Grapes what their talented progenitors have done for Peaches and Nectarines—to undertake systematic fertilising and breeding for quality? To do that well it is needful to understand in what respect high-class Grapes may be deficient in cultural, cropping, or setting requirements, and seek to amend them, just as inferior, yet easily-grown, free-setting Grapes need to have good flavour put into them. Large berries, however much they may be admired on the show boards, are far from being essential. Certainly, except to gratify vulgar, ostentatious wealth, they are not wanted on the dessert table. Of Apples every one prefers delicious Cox's Orange Pippin, even if small, to huge, tasteless Peasgood's Nonsuch, or Winter Nelis Pears to Beurré Clairgeau, and the same taste should apply to consumers of Grapes. But we must begin by reforming our exhibition requirements.

A. DEAN.

## THE UBIQUITOUS AMPELOPSIS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The suggestion made by "F. H. C." on page 340 of THE GARDEN of the 15th inst., that in reference to the very general use of Ampelopsis Veitchii, it is possible to have too much of a good thing, I have heard repeated more than once lately. While agreeing with all that "F. H. C." says as to the desirability of introducing flowering plants with the well known creeper in such a manner that as they grow the creeper may be partially withdrawn to make room for their further development, it seems that the selection of plants must be carefully considered in relation to the character of the building itself. "F. H. C." is not unmindful of this very important part of the subject, for he observes that in "a quaint old country town" known to him there is no doubt that the Ampelopsis "is smothering by rapid strides the architectural beauties of some of the old houses." The advantages of the Ampelopsis over other climbing plants, notably Ivy, have been well shown in a paper read some time ago by a well known modern architect, who pointed out that while Ivy permanently covered all architectural detail and even destroyed it, the thread-like stems did no harm and could be easily removed. This could not be the case with such woody stemmed plants as Wistaria and Magnolia. In the case of a mansion where the lower walls are quite plain, such plants could well be used, and as an illustration of this I may perhaps say that I recently saw on the front of a mansion near Kingsbridge Magnolias and Myrtles some 15 feet to 20 feet high, splendidly in flower at the same time. These were a great relief to the monotony of even the Ampelopsis beautiful as it is.

## CUTTING DOWN HARDY PLANTS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In reference to the discussion in THE GARDEN on cutting the foliage of hardy plants, may I be permitted to offer a few remarks, not to the great army of my professional brethren, but to those who are in doubt on the subject. As the simplest example, almost everyone knows that to cut off the spikes and leaves of bulbous plants in a green state, instead of allowing the sap to go back to the bulbs naturally and build up fresh tissue for another season's growth, is to weaken them for one or more years at least. Now I feel sure that what holds good with bulbs is equally as important in regard to hardy plants, the only difference being, the latter have crowns to build up with the returning sap in place of bulbs. Plants of the nature of Delphiniums, Paeonies, Dictamnus, and those having a fleshy root-stock generally are a good example of my meaning.

Why the great hurry to cut or even partially cut down a plant? My rule is, immediately a plant goes out of flower cut it neatly across just below the seed pods; leaving them on would only weaken the plant unless one wants to save seed, then a few pods may be left to mature.

There is nothing unsightly about the great majority of hardy plants although out of flower; in fact, most of them make very handsome and attractive bushes for a long time after flowering. As the tops die down they are gradually cut off. Finally, to those in doubt, it will be found a good safe rule when cutting hardy plants to put the knife through nothing in which a vestige of green remains.

F. M. U.

## ORCHIDS.

## NOTES FROM THE DELL.

## TRICHOPIA BREVIS.

A REMARKABLY well-cultivated specimen of this beautiful, but, unfortunately, very scarce, plant is now in bloom in The Dell gardens, and both from its beauty and rarity claims notice. The species was first imported from Peru in 1894 by Messrs. Sander, of St. Albans, and flowered in 1895, the plant being figured in the *Gardener's Chronicle* of that year. Botanically, the nearest relative of this species appears to be *T. sanguinolenta*, better known as *Helcia sanguinolenta*, but is widely separated from that plant, as from the other known members of the genus, by its cone-like, nearly cylindrical pseudo-bulbs—so different to the compressed pseudo-bulbs of the *coccinea* section—the colouring of the flowers, and the campanulate shape of the labellum. A coloured plate of the plant was also given in THE GARDEN five years ago, and reference to that shows a good typical form, inferior in colour and size, however, to the one in The Dell collection. The clear colouring present in this form is as remarkable as the perfect cultivation, for the general opinion of growers is that *Trichopilia brevis* is not particularly amenable to culture. The spikes are produced laterally from the base of the pseudo-bulbs, and the flowers at first sight remind one of a glorified *Miltonia candida*. The sepals and petals are rich yellow, heavily marked with confluent blotches of polished chestnut; the lip, the edges of which are beautifully frilled, is glistening white, with a few purplish marks on the base and a slight yellow tinge present in the throat; the leaves are decidedly petiolate, pointed, dull green in colour, but still retaining the stout consistency common to the genus.

## LYCASTE BALLIE.

A very handsome hybrid Lycaste, also in flower, attracted attention. Obtained from Lycaste Skinneri crossed with Lycaste macrophylla (*plana*) *measuresiana*. It was originally named by Messrs. Sander and Sons as *Lycaste G. S. Ball*, but the name was altered to the present form, Ballie. The bold, clearly-defined flowers are fully as large as those of a good *Lycaste Skinneri*, but quite different in colour. The broad sepals are a soft plum-red; the petals project forward, the edges being slightly reflexed and wholly of a bright rose-red, with still brighter red-rose spots. The same colouring is present on the outer surfaces, but in a less degree. The lip has a ground colour of creamy yellow, but thickly covered, in some places so much so as to be quite hidden by sanguineous red. Hybrids such as these form welcome additions to our Orchid collections. While quite as beautiful, judging by this example, they are the more interesting as varying so much from the numerous Cattleya and Cypripedium hybrids which form such a deservedly prominent feature in the best Orchid collections of the present day.

## CATTLEYA LABIATA.

Reference must also be made in these notes to the grand show made by that most useful of the autumn-flowering Orchids, *Cattleya labiata*. At The Dell, in spite of the number of plants in flower, no two varieties are alike and no poor forms are visible. The plants are pictures of vigour and health, evidenced by the number of flowers on the stout, strong spikes. A white variety is conspicuous from its chaste whiteness, broken only by a shade of pink on the segments and crimson lines and purplish markings on the labellum. Near it are other forms of this beautiful *Cattleya* in many shades and shapes, but all of them excellent.

In the same house, among a host of other incomparable species and varieties, is a grand specimen of that truly wonderful form of *Cattleya bowringiana* known as The Dell variety. This is by far the finest *bowringiana* known, surpassing all others in the size of its blossoms, the depth of their purple colouring, and the number produced in a single inflorescence.

ARCTUS.

## THE RESTING OF ORCHIDS.

THIS very important operation, the resting of Orchids, is one which is often misunderstood. It is an operation too often carried out indiscriminately by novices and others. Many persons imagine that resting simply means the withdrawing of water for a definite period after growth is completed, but to the ardent cultivator the term means something more, for the same treatment does not suit all species. For instance, although *Odontoglossums* require a certain amount of rest, yet it is disastrous to withhold water as you would in the case of *Dendrobiums*. Or take again *Cypripediums* and certain species of *Cattleya* it is obvious that the former do not need a drastic drying off to the same extent as the latter. These will serve as examples. Before we proceed it will be well to find out what the term "rest" does really signify. Briefly it may be said to be a cessation of growth for a short period, commencing when the growth is completed and thoroughly ripened until it commences flowering. As soon as the plants show their flower-spikes their rest is over and their growing season has commenced, though it must be borne in mind that until the growths have actually started water must be sparingly administered. *Pseudo-bulbous* species of Orchids mostly require a dry rest, whilst the ever-green bulbous species require a rest, but that in a limited form, inasmuch as they require to be kept moist at the roots throughout the year.

The resting of Orchids requires more attention on the part of the cultivator than when the plants are in full growth, and experience alone will show to what extent the operation may be carried out. *Dendrobiums* require very careful attention as regards their resting period. The growth must be quite completed before the water supply is gradually withdrawn, and great care must be exercised after the deciduous species have shed their foliage so to supply them with water that the shrivelling of the pseudo-bulbs is prevented. A necessary item when resting Orchids is that of fresh air. This may be supplied on all favourable occasions, great care being taken to avoid draughts, which are disastrous.

J. DENMAN.

*The Laurels, Cains Cross, Stroud, Gloucester.*

## NEWLY IMPORTED ORCHIDS.

THE season of Orchid importation being now in full swing a few words as regards the treatment of the same may not be altogether superfluous. The plants as bought from the auction or sale-rooms are invariably in a dormant state, and often they are found to be shrivelled up and in an unsatisfactory condition owing to the long journeys by land and sea which they have travelled. It is obvious then that these Orchids require careful treatment and nursing to bring them back to health and vigour. The first thing to be done

when an importation is received is carefully to unpack them, and afterwards place each individual plant upon a bed of damp moss, in a temperature of about 60°, and keep them and the surroundings constantly moist. Provided these conditions are constantly provided the young growths will soon start, but before they do so a thorough cleaning of every part of the plants is essential. This fact should always be borne in mind, because if neglected the result will be a rapid spread of scale and maybe thrip, which when once established will be hard to exterminate. Each plant should be dipped in a solution of soft soap, which tends to soak the dirt, &c., and will be easily removed afterwards by the use of a soft sponge. During the sponging operations great care should be exercised so as not to damage or rub out the eyes at the base of the pseudo-bulbs, as should this happen the growths may be weakened. When the plants have fairly started into growth they should be placed in a higher temperature, as a matter of fact they may be grown for a time in a temperature 5° or 10° above that they receive when established; they should be constantly kept moist by a frequent use of the syringe and tepid water. If preferred the plants may be suspended from the roof of a warm house, the same conditions being provided as otherwise.

Directly the young growths begin to make headway or roots begin to form the plants should be potted up in pots corresponding to the size of the plants. On no account should they be overpotted. For the first season they may be grown in pots almost filled with crocks, a little peat and sphagnum only being used to keep them in position. Such Orchids as Cypripediums, Vandals, &c., may be potted up as soon as received, but Cattleyas, Odontoglossums, Dendrobiums, &c., are best treated as advised above. If the plants become established they may in the following year be potted up in small pots, using a compost of peat, leaf-mould, and sphagnum, an abundance of moisture being constantly maintained.

J. DENMAN.  
The Laurels, Cains Cross, Stroud, Gloucestershire.

*Little Marvel* (Sutton), an excellent early Pea of really dwarf habit, not being above 15 inches high, carries a very good crop of square-ended pods in pairs, tightly packed with dark green Peas of excellent flavour.

Of course any number more of dwarfs might be mentioned, but my aim is not to describe all the varieties in cultivation, but to bring into prominence the most worthy. Among the

TALLER-GROWING EARLIES,  
*Grulus* (Laxton) takes a leading place; there is no early wrinkled Pea to beat it, if a good stock is obtained.

*Thomas Laxton* (Laxton) is quite an acquisition; perhaps it may be best described as an early and dwarfer form of *Ne Plus Ultra*. Good crop of dark green square-ended pods, containing an average of about eight large Peas; flavour XXX. The crop continues fit for use for a long time; 4½ feet; July 18.

*Empress of India* (Sutton), an excellent variety to follow the very earliest, a very heavy cropper, and the pods are very well filled; grand flavour for an early Pea; height 4 feet.

*Magnificent* (Johnson).—This is a very fine second early, carrying an exceptional crop, pods nearly always in pairs, square-ended, dark green; flavour excellent; 3 feet.

*Boston Unrivalled* (Johnson) bore an immense crop of long-pointed pods, in shape just like *Duke of Albany* but lighter in colour; very good flavour when cooked, the best of this class of Pea; 4½ feet; ready July 29.

*Alderman* (Laxton).—Very good crop of long, dark green pods like *Duke of Albany*, but a few days later; excellent flavour; 5 feet to 6 feet.

*Kelvedonian* (Hurst and Son).—This Pea carried a tremendous crop of square-ended pods, longer than *Ne Plus Ultra*, containing very large Peas of good flavour; height 4 feet; ready July 30.

*The British Empire* (Johnson).—Very good crop, pods in pairs, pointed, well filled with deep green Peas of excellent flavour. The haulm of this variety might appear objectionable to some growers, as it has a peculiar shiny appearance, looking as if it had been

syringed with insecticide, but after all we do not boil the leaves but the Peas, and they are really excellent and remain fit for use perhaps longer than any other variety; 2½ feet; August 1.

*Prizewinner* (Sutton).—This must be placed among the "best six Peas"; good crop of exceptionally long, dark green, pointed pods, well filled with large Peas of the finest Marrow flavour; good alike for exhibition or table; very robust growth; 3½ feet; ready August 10.

*The Gladstone* (Holmes).—I find this cata-

PEA PRIZEWINNER.

logged as a second early and described in the Journal of the Royal Horticultural Society as having nearly straight pods, neither of which points agree with our trials. I have always found it a decidedly late Pea, with very curved pods; very good crop of long pods, well filled with dark green Peas of good, but not best, flavour; a sturdy Pea, which seems to have a good constitution, and would probably succeed where many others would fail; 4½ feet; August 15.

## THE KITCHEN GARDEN.

### PEAS IN 1902.

#### DWARF PEAS.

HERE at Lowdham the past season has been a particularly good one for culinary Peas. Never have I seen finer rows in our trial ground, and never have they lasted longer in bearing, some varieties having been in eatable condition for quite three weeks. I think a few notes on this most useful vegetable may be of interest to readers of THE GARDEN. Of first early dwarfs I give the palm to

*Harbinger* (Sutton). It proved itself the earliest wrinkled Pea on trial; in fact, came in to the day with *William I*. It is a very good cropper, and the flavour is excellent, quite as good as many of the later Marrow Peas.

*Chelsea Gem* (Veitch), which grew this season 2½ feet, bore a fine crop of moderate-sized well-filled pods four days later than *Harbinger*. This is a really good variety and is now very well known.

For my own part I think we could dispense with *American Wonder* and perhaps *William Hurst*. Neither of them are so early or so good as *Harbinger*, but of course the question of soil must be taken into account, for a variety which succeeds on one soil will often turn out poorly on other soil.

*Pierremont Gem* (Barr) stands out as an extra good dwarf Pea to follow the earliest ones; good crop of rather long square-ended pods, well filled with dark green Peas of excellent flavour; ready nine days after *Harbinger*; 2 feet.

*Late Queen* (Sutton).—An excellent variety, one of the latest; good crop of dark, square-ended pods; large Peas of finest Marrow flavour. This, along with several of Messrs. Sutton's highly-bred Peas requires good soil and cultivation to do it justice.

*Autocrat* (Veitch).—With us the latest and quite one of the best; habit robust in the extreme; good crop of the best quality; should be tried by everyone.

One point has been very much impressed upon my mind of late, namely, the way in which a race of hardy wrinkled Peas has sprung up to take the place of the little round-seeded varieties of ten to twenty years ago. Really there is now no place at all for round-seeded Peas unless it be for autumn sowing. Of the round-seeded I think old William I. is still the best in quality and as early as any.

There has been a great increase of late in the popularity of the dwarfs, and it is not to be wondered at. Firstly, sticks are getting scarce and dear, especially near large towns; and, secondly, the dwarf varieties have been so much improved. Many people contend that the dwarfs do not bear so well as the taller ones, but when one considers that twice as many rows may be grown on a given space, it is easily seen that as good returns may be had from the dwarfs as from their taller brethren. Again, there is saving in time in the sticking, though I think it well worth while to give even the dwarfest of Peas a little support either in the way of brushwood or sticks and strings.

There is no need to grow Peas of inferior quality while we have such a host of really fine ones of equal or superior cropping capacity. As before hinted, some Peas will succeed on land which will not grow others. The best plan is to try a good number and select a few which suit the land best. Many gardeners will order nearly every Pea one has in one's catalogue, in which cases there must be many sorts coming into use at the same time. It would be far better to have fewer varieties, more of each, and make successional sowings.

Rows of Peas are generally—indeed, almost always—placed too near together, so that little sun and air reaches the lower parts, the consequence being little or no crop on the lower part of the haulm. I am perfectly sure that if cultivators would only give their Peas more space they would get heavier and better crops. In our trial grounds we always allow 6 feet between all the tall Peas and proportionate space for the dwarfs.

In these notes there will be missing many a good Pea worthy of mention, but I have purposely avoided the very old friends, such as Prince of Wales, Ne Plus Ultra, &c., as being too well known to need description or comment, while of the newer varieties I have only written of such as have come under my personal observation.

J. D. PEARSON.

*Chilwell Nurseries, Lowdham, Notts.*

#### VEGETABLES IN SEASON.

##### DWARF FRENCH BEAN CARTER'S NEW HOLLOW WONDER.

This class of dwarf Bean, of which the above is one of the best of the type, is somewhat forgotten. I allude to the stringless green-podded Bean, that previous to cooking needs little preparation. The pods should not be cut at all but cooked whole in a young state. If not liked in this way they may be broken, not cut. This new Bean is also valuable for its heavy cropping, and, I may add, it forces well. On the Continent this kind of Bean and the Butter Beans are more valued than the ordinary ones grown in this country. This new

variety is not unlike the Butter Bean, except that the colour is different, Carter's being a green-podded variety. I have in a previous note last year alluded to the Butter Beans, so I only briefly allude to the type on account of its stringent character.

##### CAULIFLOWER EARLY EMPEROR.

As there are several excellent Cauliflowers for summer use any new introduction must have specially good qualities to prove better than those already in existence. Last season the new Early Emperor of Messrs. Carter and Co. was sent to me for trial, and it is certainly a grand acquisition for earliness, as, though an early summer Cauliflower, it is quite as valuable for sowing in heat early in the year and growing on for first supplies afterwards. Last season this variety sown the first month in the year in a frame was fit for use the same time as plants sown in the open in August. Given frame protection through the winter I can strongly advise this variety for planting in the open, say, the end of February or early in March for summer supplies. It is certainly a most choice vegetable: the heads are very white and close, and, though large, they are of first-rate quality. The growth is compact, the latter being a great gain in a private garden, and, having such a delicious flavour, makes it doubly valuable. It is the earliest spring Cauliflower I have grown, and this season I hope to give it a much larger space, as it is so much liked.

##### EARLY TOMATO WINTER BEAUTY.

To recommend the culture of Tomatoes at this dull time of the year may appear out of place, but it is necessary to sow seed in the early autumn to get a supply in early spring. For the past two seasons Winter Beauty has proved invaluable for its free setting and good cropping; it also matures earlier than many other kinds, and early in the season the latter point is a great gain. At that date Tomatoes are very scarce and a choice vegetable is much prized. There are other so-called winter Tomatoes, but the Winter Beauty is a splendid addition on account of its free setting qualities. Another point well worth attention is that the fruits are of good quality, nearly smooth, of medium size, and a rich colour. For early spring supplies I advise pot culture. Sow the seeds thinly in October, and if sown later it is well to raise in heat and place the seedlings close to the glass from the start. I have never grown any winter plants that gave so good a return as Winter Beauty. Grown in 8-inch or 10-inch pots for fruiting, the plants crop heavily, equal to the best summer Tomatoes.

##### PEA SUTTON'S LATE QUEEN IN NOVEMBER.

In November lovers of good vegetables do not expect to get Marrow Peas of the best quality, but the above variety is good all through October, and later if the season is mild. For many years one of our best late Peas was Sutton's Latest of All, and I considered it a very fine variety, but certainly the older variety is eclipsed by the introduction of Late Queen. Its height is from 3 feet to 4 feet, and these medium-growing stony haulm varieties are of greater value than the tall ones. I have referred to the flavour, and in this respect it equals the well known Ne Plus Ultra; the pods are dark green, densely covered with bloom, and the Peas large and remarkably sweet for this time of year. Another strong point in the culture of this late Pea is its freedom from mildew and the way the flowers set so late in the season; the pods fill well and are of splendid quality at the season noted. Being a strong grower the plant to do it justice needs ample space, and, given a good root run, it is enormously productive.

G. WYTHES.

**Mr. Richardson**, late of the Edinburgh Botanic Gardens, who has started business as a landscape gardener was the recipient the other day of a handsome album containing the names of his well-wishers in his new start and a cheque for £55. Mr. A. D. Mackenzie, of Messrs. Mackenzie and Moneur, Limited, made the presentation. Mr. Richardson, it may be added, has been engaged for several years in carrying out the improvements in the botanic gardens.

#### GARDENING OF THE WEEK.

##### INDOOR GARDEN.

###### CHRYSANTHEMUMS.

**C**UTTINGS for trained specimen plants should now be put in. An important point is to have good strong cuttings about 3 inches long cut across below a joint. For large trained plants I prefer stout sucker growths taken off with roots attached. These start freely and will not require any fire-heat, only protection from frost. The cuttings should be inserted in small pots well drained, and filled with a compost consisting of loam and leaf-soil in equal parts, with enough sharp sand to make it porous. On the top sprinkle sand, press the soil firmly round the cuttings, and water with a fine rose water-pot, place the pots in a frame and keep close until rooted. A little air should be admitted for about an hour in the morning to dry up excessive moisture. Many of the late and weak varieties for large blooms may now be struck, but for the general collection I prefer the end of December and early January. In any case the old stools should be placed in a cool airy house, kept as near the glass as possible, and the weakest shoots thinned out in order to afford short stout cuttings.

###### PLUMBAGO ROSEA.

This is a splendid plant to grow where quantities of winter flowers are required for cutting. It also forms a useful pot plant, and the lovely rosy scarlet flowers are very striking when arranged among foliage plants in the stove house. This plant resents moisture overhead when in flower.

###### LILIUMS.

Imported bulbs should be potted as soon as they arrive. Fibrous loam and peat in equal parts with a free admixture of crushed charcoal and silver sand will form a suitable compost. Good drainage is indispensable. Dry powdered charcoal should be shaken over and underneath the bulbs. In potting the bulbs should only be partially covered until growth commences, after which the pots should be filled, as it is very important that the upper roots should be well covered with soil. After potting place them in a cool pit or frame protected from frost. Water should be given very sparingly at first, and the quantity gradually increased as growth progresses.

*Wixham Park, Slough.*

JOHN FLEMING.

#### THE FRUIT GARDEN.

##### EARLY VINYERY.

REFERENCE has been made respecting the starting of a house of pot Vines and a permanently planted house, containing such early varieties as the Black Hamburg, Foster's Seedling, and Madresfield Court, having been previously prepared, should now, or at an early date, be closed. A moderately small and comparatively low house, provided with inside borders, is suitable for early forcing, but should there be outside borders they should be covered with a bed of warm leaves sufficient to keep them warm—a protector sufficient to exclude rain being necessary to ensure this. In the case of an inside border see that it is moist throughout by watering, if it is necessary, with tepid liquid manure. Should the Vines have young rods bring their points near the surface of the border in order to equalise the flow of sap and cause their buds to break regularly. Afford sufficient artificial warmth after the house has been closed a fortnight to keep a night temperature of about 50°, that for the day being about 55°.

###### EARLY PEACHES AND NECTARINES.

A house for an early supply of fruit should be closed early in December. In commencing forcing at this date it is necessary, in order to avoid failure, that a house possessed of trees that have been accustomed to being forced early should be made use of, and even in taking precautions of this kind it is essential to take great care not to excite the trees into growth by the excessive

employment of artificial warmth. Commence forcing with a night temperature of from 40° to 45°, with an increase, according to the weather, of from 5° to 10° by day, allowing it to reach 65° from sun-heat, but once the buds begin to move a general increase of a few degrees may be safely allowed.

## STRAWBERRIES.

The mild condition of the weather has caused pot plants to continue growing late; there must, however, be no further delay in placing them in their winter quarters. We find space for those to be early forced in cool frames, and firmly plunge the remainder in beds of fine ashes, protecting them in severe frost with clean litter or Bracken. The most successful results usually attend plants that are not forced until the new year, but for giving early gatherings of fruit a batch of plants should be introduced into warmth early in December. These may consist of such early varieties as Vicomtesse H. de Thury, La Grosse Sucrée, and Royal Sovereign, leaving the later kinds for subsequent use. Remove old and decayed leaves and the immediate surface soil, replacing it with a compost of good loam made quite firm mixed with fine stable manure and a suitable artificial fertiliser.

Monmouth.

T. COOMBER.

## THE FRUIT GARDEN.

## APPLE RIVAL.

MESSRS. W. CLIBRAN AND SONS, Oldfield Nurseries, Altringham, Cheshire, are the raisers of this new Apple, which was given an award of merit by the fruit committee of the Royal Horticultural Society on October 9, 1900. It resulted from a cross between Cox's Orange Pippin and Peasgood's Nonsuch. Apple Rival is a large, handsome, and beautifully coloured fruit; even this season, when hardy fruit has been unusually colourless generally, this variety, as we recently saw it, was of remarkably good colour. The fruit is considerably larger than Cox's Orange Pippin, and the rich flavour is very similar to that of the latter, while the flesh is very firm. We should say it is an Apple that would keep well. The tree is described as "a free grower, with upright habit, a good cropper, and well adapted to orchard culture." With such characteristics and an appearance that strongly recommends it Apple Rival should become a favourite.

## HARDY FRUITS IN SEASON.

## PEARS.

BARON LEROY.—This new fruit is well worth attention on account of its good quality. It much resembles a well-grown Chaumontel in appearance, and when grown in bush or pyramid form on the Quince stock it is valuable in November. In Belgium and on the Continent it is a great favourite, and this season our fruits grown on cordon trees have been very good, both as regards quality and size, and young trees are very productive. Of course quality is the test, and it may be stated that in this respect Baron Leroy much resembles the well-known Passe Colmar, a beautiful fruit and a great bearer in a warm soil. In this country the Chaumontel is not a great success in many gardens. In Jersey it is excellent, and my reference to its similarity to the new variety only refers to the appearance and size of the fruits.

Doyenné du Comice.—At this season no note would be complete that did not include the Queen of Pears Doyenné du Comice. Though I fear in many districts this variety is past,

they are at their best in the southern parts of the kingdom. My note more refers to the east and northern portion, as the fruits are good well into December. It is very strange how well Comice thrives in apparently unsuitable positions, as this season I have seen some grand fruits in the eastern and northern counties, and there should be no hesitation about planting this good kind in different positions, as by so doing a long supply is maintained. In the south the trees do well in the open. I need not describe the fruit; it is well known, but at the same time many amateurs hesitate to plant some of the best varieties, thinking they are poor croppers. Though Doyenné du Comice is not always a sure bearer, I find by having trees in different positions we get quite as good crops as from other varieties, and in the north and eastern counties the trees bloom later and often escape frost, which cripples those in earlier districts.

*Beurré Baltet Père.*—A very fine fruit when grown on a wall, and most suitable for cordon culture. It is in season at the end of November and the early part of December. Of course as regards quality Beurré Baltet is not equal to Doyenné du Comice, but it is a grand bearer and a Pear of excellent quality. It thrives well as pyramid or bush in the south, but in the north should be given wall culture. We place it in the list as one of our most useful varieties for the season named, and it is excellent for market. For some years I have grown this in place of the softer and inferior Beurré Bachelier, as the latter decays so quickly when ripe, travels badly, and soon shows signs of rough packing. Baltet Père is a firm fruit and freely produced.

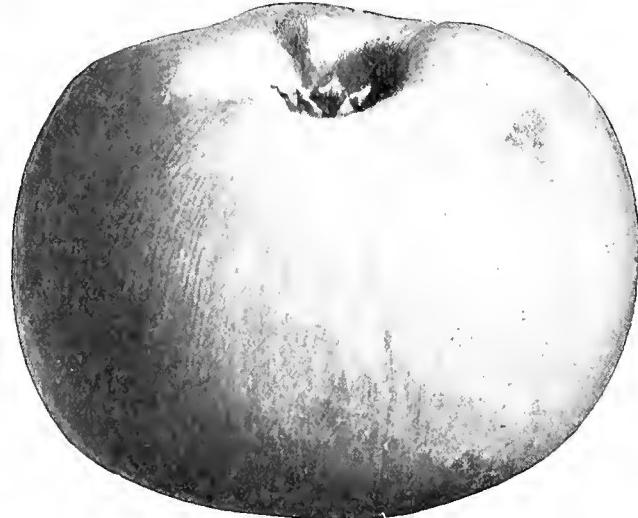

## THE BANANA.

An illustration of *Musa Cavendishii* that I send you in fruit—[unfortunately this cannot be reproduced.—ED.]—reminds one that the delicious Banana can be successfully produced in our hot houses at home; indeed, the flavour of fruits thus obtained is generally far superior to that of imported ones, doubtless chiefly owing to the fact that the ripening period of the former is passed under more natural [if one may here use the term] and suitable conditions than are enjoyed by the latter, the majority of which must necessarily be gathered while still in a green state. The number of gardens where Musas are cultivated for the value of their fruits appears to be very limited, though as ornamental foliage plants they are in much more general request. Summer visitors to the London parks cannot have failed to notice the beauty and effectiveness of them planted out, or plunged below the surface of the ground in some of the more sheltered parts. Many of our warm greenhouses, too, are the richer and more attractive by the presence of these handsome plants. Those of us who have had the pleasure of visiting the sunny south of France will call to mind how the Musas play no insignificant part in the adornment of the unique gardens to be seen there.

Though the large and striking foliage is a most pleasing addition to any sub-tropical bit of garden, it is also tender, and very easily torn and disfigured by cold winds or slight frost. Probably one general reason of the unpopularity of the Musa as a fruit-bearing plant is because of the comparatively large amount of space required to allow of its proper development. With *M. Cavendishii*—the most suitable for this purpose—however, the

above evil is to a large extent disposed of, for the plant shown in the illustration was but rather more than 5 feet high. In a house whose dimensions are 40 feet long by 20 feet wide the centre is occupied by a bed measuring in length 34 feet and in width 7 feet. This is filled with loam well enriched with manure, in which two rows of plants were placed. The side stages of this house are utilised for the cultivation of small plants in variety, and the trellis overhead is partially covered with *Passiflora edulis* and *P. quadrangularis*, both of whose fruits are used for dessert. Night temperatures of 70° to 75° Fahr. during the warmer and 60° to 65° in the colder months are maintained.

The *Musa* grows rapidly when once it becomes established, and delights in a rich vegetable soil. In about twelve months from the time of planting (presuming that the Banana plant then is from 2 feet to 3 feet high) it should be sufficiently vigorous to produce a bunch of flowers. A great deal depends upon the period at which the flower spike appears as to when the fruit may be expected to ripen. If in the spring of the year the fruit would, under favourable conditions, be mature by the autumn. If, however, the spikes were not produced until late in the year, thus having to develop during the dull and sunless winter months, the Bananas most probably would be small and deficient in flavour when ripe in early spring. A

APPLE RIVAL.

plantation of *Musa Cavendishii*, if given a liberal top-dressing of rich soil annually, will remain in bearing for many years. After having borne fruit the plant dies down, and suckers grow from around the base of it. Unless a large amount of space is available, only one of these should be allowed to develop, which, if vigorous and healthy, may be expected to flower and fruit the following season; some plants, however, need a longer time before they are capable of producing flower-spikes.

A. P. H.

## AMERICAN NOTES.

## SOME PLANTS OF NEW JERSEY.

THE coast region of New Jersey is not specially notable for landscape beauty, being rather flat, sandy, and uninteresting from a scenic point of view, but botanically it possesses much that is interesting and some things that are out of the common.

This section of country seems to be a sort of meeting place between the flora of the Southern States and those that are looked upon as belonging to the North, and in consequence one who is familiar with these things may often make discoveries. One of the most striking features of the

marsh land near the ocean is found in great fields of the Rose Mallow (*Hibiscus Moscheutos*), one such field that I recall with much pleasure being found in the vicinity of Wildwood, New Jersey (a summer resort in the southern part of the State), and covering fully 5 acres and possibly more, the growth of the Hibiscus being from 3 feet to 5 feet high, and in the early part of August being a mass of flowers.

The flowers of this Hibiscus are large, frequently 5 inches or 6 inches in diameter, and while the predominating colour is pink, there are several distinct varieties, among them being a pure white one, and also a white one with a crimson centre, all of which seem to grow with equal vigour in this natural flower garden.

The Rose Mallow may be readily grown from seeds, and is by no means difficult to cultivate, but the finest specimens are those found in these more or less saline marshes near the coast. And right along the beach, perhaps not more than 100 feet beyond the reach of the tides, we often find the Sea Rocket (*Cakile maritima*), a plant that reminds one of a strong growing white Candytuft, having rather succulent leaves and freely branching in habit.

One reminder of the flora of the more Southern States that is much in evidence in a certain locality on the coast of southern New Jersey is a great number of Holly trees, many of which are wonderfully prolific in berry-bearing, a condition that is probably to be accounted for by their environment, the soil being poor and thin, and the trees so much exposed to strong winds from the ocean that many of them present a singularly stunted appearance. Many of these Holly trees are not more than 15 feet in height, flat topped, with long horizontal branches on the land side of the tree, and much shorter growth on the side toward the ocean, the annual growth being very short and twiggy and the leaves small.

The Hollies in question are mostly located within half a mile of the ocean, and so plentiful are they in that particular strip of woodland that a resort near by has been named Holly Beach. Another somewhat unusual feature among the plants of that latitude is found in the form of a considerable number of specimens of the Trumpet Vine (*Bignonia* or *Tecoma radicans*), a vine that is much more common in the south, and one that is valuable for covering a rustic arbour or to gracefully drape a dead tree, its foliage being but little troubled by insects, while its clusters of orange flowers are very attractive. Then in the swamps, but a few miles back from the shore, there is a wealth of botanical treasures, among them being the Huntsman's Cup (*Sarracenia purpurea*), the most northern representative of the Pitcher plants, the leaves or pitchers of which are beautifully marked with purplish crimson. The Sarracenia in question is found growing in a peaty bog usually surrounded with a bed of sphagnum, and is thoroughly hardy, those plants that are much exposed to the sun generally displaying the most colour in their pitchers, though there are doubtless variations in this plant as there are in the other species of Sarracenia that are found growing in the South Atlantic States. Among the minor growths in the same swamps may be found some two or three very pretty Sundews, *Drosera rotundifolia* being the most common, while *Drosera longifolia* and *D. filiformis* are also found occasionally, all of which may readily be naturalised in the bog garden with the Sarracenia. In swampy woodland we also find the Rattlesnake Plantain (*Goodyera pubescens*), a charming member of the Orchid family, with leaves well reticulated with white, and though the flowers of this plant are not very striking, yet it is well worth growing for its foliage alone. This *Goodyera* is not very plentiful, and I have never found it growing in colonies, but only as single specimens, and usually located at the base of a tree.

On the outskirts of the swamps several other Orchids are to be found, and some of them are remarkably pretty ones, too. The White Fringed Orchis (*Habenaria blepharoglossa*) and the Yellow Fringed Orchis (*H. ciliaris*) are both found sparingly, and are decidedly worth hunting for, while *Arethusa bulbosa*, with its usually solitary

large purplish pink flower, and *Pogonia ophioglossoides*, that throws up a slender spike bearing one to three pink flowers, are both found quite frequently among the grasses in the low ground, the latter species being variable in colour, occasional specimens appearing that are either bluish or white. And on higher ground, frequently in Chestnut woods, the Stemless Lady's Slipper (*Cypripedium acaule*) is quite common, some of the flowers of this species being very large and beautifully coloured, deep pink being its most common colour, though varieties that are almost white are sometimes found.

In the same locality, or in woods of a similar character, in the month of June, that most singular root parasite known as Indian Pipe (*Monotropa uniflora*) is often found in bloom. This oddity grows from 4 inches to 6 inches in height, and is usually found in clusters, the stem, scale-like leaves, and strange-looking flowers being white and waxy, and altogether uncanny in appearance. The Indian Pipe does not last long, but after forming seeds soon turns black and shrivels up, and a few weeks after its usual season of blooming it would be rather a difficult matter to locate it. I have never seen the *Monotropa* in cultivation, and do not know whether one would be likely to succeed in raising it from seed, nor would it be of any special value unless it were to the managers of some botanical garden who were desirous of making a complete collection of ericaceous plants, to a sub-order of which *Monotropa* belongs. And in the autumn and late summer there are hosts of other and more showy species to be found in the woods and swamps, for example, *Lobelia cardinalis*, *Liatris* or *Blazing Star*, *Empetrum purpureum*, and others of the same family, the Meadow Beauty (*Rhexia virginica*), all of which may be found before the grand display of Golden Rod and Asters lights up the woodland toward the close of the season.

Holmesbury, Philadelphia, Pa.

## MISCELLANEOUS.

### NOTES FROM THE EDINBURGH SHOW.

**M**UCH interest is always excited by the contest for the City of Edinburgh Cup, now called "The Victoria Memorial," value £20, with £10 added, for twenty varieties of Chrysanthemums, three blooms of each, arranged in vases. There were seven competitors this year, two of whom were from England, one from Ireland, the rest being Scottish growers. Between one of the latter, Mr. Lunt, Keir House, Stirling, and Mr. Kenyon, Woodford Green, Essex, the real struggle for the cup lay. The blooms of the latter were somewhat wanting in finish, while those of the Scottish grower were remarkable for their high finish and the care with which they were staged, no point being neglected. The result of the judges' deliberations was that Mr. Lunt for the fifth time secured the cup, and Mr. Kenyon had the second prize of £20. In the first prize lot Princess B. de Brancova, a lovely white variety with very long petals, was awarded the silver medal for the best Japanese bloom in the show.

#### MR. GODFREY'S EXHIBIT.

All the way from Exmouth Mr. Godfrey had brought a magnificent lot of blooms, to which the only gold medal given to non-competitive groups was awarded. This contained many of the finest sorts raised by Mr. Godfrey, as well as those of other growers. Apart from the Chrysanthemums, Messrs. Todd and Co., florists, Shandwich Place, arranged the most attractive exhibit. It consisted of a floral display in great variety, such as wedding bouquets, harps, &c., and was, perhaps, most remarkable for the good taste displayed in the choice of colours and their arrangement. It was worthily awarded a prize of £20. A feature of this show consisted of the large number of bunches of Grapes that were staged for a few prizes. Given

a little more encouragement and this late exhibition would rival the September meeting in this respect. Mr. Leslie, Pitcullen House, Perth, carried off some of the chief prizes with the veteran grower Mr. Kirk, of Norwood House, Alloa, who exhibited the finest Muscats seen at Edinburgh this year. Apples were fairly well shown, but the fruit generally was below the average in size, and the chief prizes went to English growers. In Pears, however, the Scotch growers were more successful, fine fruits in the best varieties being staged by Mr. Moir, Rosehaugh, Avoch, and others. Doyenné du Comice, Pitmaston Duchess, Princess, Marie Benoist, and Balbet Père being the best.

Vegetables, too, were wonderfully fine. Such Leeks can only be produced in Scotland, and in what quantities they were beamed on the tables, the collections with which Mr. John Waldie, Dollar-beg, Dollar, secured both first prizes being particularly fine. Messrs. Laing and Mather, Kelso, had on view the winning lots of Lym Leek, for which the firm offer prizes, and by Messrs. Dobbie and Co. a large and interesting collection of Potatoes was shown. Samples of a new Scotch variety, said to be the Potato of the future, were exhibited under a protected case by Mr. Scarlett, Inveresk. It is named Northern Star, and along with King Edward VII., another new variety, may be worth the attention of growers. The exhibition was open on the 13th, 14th, and 15th inst., the receipts at the doors being larger by £60 than last year, the total amount taken being about £960.

## SOCIETIES.

### BOLTON CHRYSANTHEMUM SHOW.

THE sixteenth exhibition of this society was held on the 7th and 8th inst., in the Albert Hall. The exhibits throughout were of the usual excellence as generally staged at this show, and the committee to give more room and increased comfort very wisely utilised the spacious upper corridor for the vegetables and other amateur exhibits. On entering the hall the visitor was at once charmed by the fine group arranged for competition which was fully up to the high position gained by Bolton in this particular sphere. For the group 12 feet square, the silver challenge cup, presented by E. T. Crook, Esq., in addition to the first prize, was won by J. W. Makant, Esq. (gardener, Mr. H. Shone), with a combination of much elegance; E. T. Crook, Esq. (gardener, Mr. J. Wainwright), followed with a very bright lot.

For group of Chrysanthemums and foliage plants, the first prize, which included the handsome silver challenge cup given by J. H. Hargreaves, Esq., was secured by J. Harwood, Esq. (gardener, Mr. W. Burgess), with a meritorious lot of blooms; second, Mrs. Tillotson (gardener, Mr. T. Horrocks). For an artistic arrangement with mirror at back, with a height of 8 feet and depth of 5 feet, the first prize was well won by James Musgrave, Esq. (gardener, Mr. J. Abbott), with a charming display; Mrs. E. Ainsworth (gardener, Mr. T. Travena) was second.

#### CUT BLOOMS.

For twelve incurved and twelve Japanese, distinct, the first prize (accompanied with a ten guinea silver challenge cup presented by J. Edge, Esq.) was won by E. Ellis, Esq. (gardener, Mr. J. Davis), with a fine stand, Japanese especially being good; W. Holland, Esq. (gardener, Mr. W. Barber), Liverpool, was a good second. For twenty-four Japanese not less than eighteen varieties, Edward Evans, Esq. (gardener, Mr. C. Jones), Spital, led with a good stand; Mr. W. Barber was again in the second place.

For twelve vases of flowers with stems not less than 15 inches long, Mr. H. Shone was the winner. For six vases, Mr. T. Horrocks was successful, and for one basket Mr. J. Mosley was the victor.

For six large flowering Chrysanthemums (the silver challenge cup presented by W. Grierson, Esq., being added to the first prize), T. Walker, Esq., had the premier lot, followed by Mr. H. Shone.

In the local classes for twenty-four cut blooms, twelve incurved and twelve Japanese, first prize (with a silver cup presented by the president, W. H. Lever, Esq.), was secured by W. Echersley, Esq., with a fair exhibit. For twelve incurves, E. T. Crook, Esq., was the winner, and for twelve Japanese, G. Shaw, Esq. Other first prize winners in this section were Messrs. W. Grierson and J. Musgrave.

The leading prize winners in the vegetable classes were Messrs. R. Fairhurst (who secured the bronze medal of the Royal Horticultural Society), W. Barnes, B. Barlow, and J. Bromilow.

Amongst the miscellaneous exhibits was a fine exhibit of cut blooms by Mr. Norman Davis; Messrs. W. Wells and Co. contributed an excellent stand; Mr. W. Westwell, Bolton, sent a collection of greenhouse, flowering, and foliage plants; Mr. Peter Leigh, Eury, Palma, &c.; Messrs. Caldwell and Sons, Knutsford, Palms, Heatha, Begonias, &c.; Mr. John Rolston, Altringham, Cattleya labiate, Cypripediums, Bovariads, &c.; and Mr. House, Bristol, his well-known types of Violets. The arrangements, as usual, were most satisfactory under the supervision of Mr. R. Smith, chairman; Mr. H. Shone, treasurer; and Mr. Herbert Makin, secretary.

# THE GARDEN

No. 1620.—VOL. LXII.]

[DECEMBER 6, 1902.

## A GENERAL LETTER.

"VIATOR" writes the following interesting letter :—

### ROSES IN AUTUMN.

It was with pleasure that I read your refreshing remarks about

Roses in autumn in THE GARDEN of last week, and I hope they will wake up secretaries of exhibitions without original ideas to a sense of their duty towards the long-suffering patronisers of their displays. The National Rose Society I have always regarded as a pleasant body of devoted amateurs, actuated, not so much with a desire to make Rose exhibiting popular, as to teach a much-to-be-pitied public that lovely varieties are waiting to be planted in their hungry-looking plots. Why this beneficent society, with a hallowed past, and a delightful future—for anything connected with Roses must be delightful—has not instituted an exhibition in autumn passes even my somewhat dull comprehension. I will therefore tell the readers of THE GARDEN, a journal that has done so much to foster a love for garden flowers of all kinds, about my Rose garden this autumn. It has shed its sweetness over the whole village, and the Rose garden of so-and-so has become a kind of Mecca to the surrounding inhabitants, not without a strain, let me tell you, on the patience of the proprietor.

It is one thing to own a garden and another to keep in remembrance the fact that it really is a private possession. When the sun of early spring steals across the garden, and the Daffodils open their golden chalices to drink in the warm rays, then the neighbours and those who are not neighbours ask to see the flowers, sometimes with good intentions, but also sometimes to pass away an idle hour, till one loses patience, and exclusion becomes a dire necessity, except to those who are welcome because they wish to learn and spread abroad in their own villages the sweetness they have discovered in my, as they say, and I suppose it is true, "interesting retreat." So ye who own small gardens where the visitors cannot lose themselves be wary of the idler and the lady who declares in one's very presence "that all is perfectly charming. Thanks so much for a pleasant afternoon." I have heard that said of a girl's tea-party.

This is a sad digression, because I am going to write about autumn Roses, a letter from a Berkshire garden near the river, so I hope the editor will pardon its length, as the subject

of Roses is enticing, and once entered upon the pen runs away with all proper restraint. The leading article last week was about Roses in autumn, an excellent heading, and one that emphasises the great beauty of our national flower in the month of Starworts and Flame flowers of Golden Rods and ruddy leaf tints.

Sometimes, alas! after the first breath of frost comes the smell of putrid vegetation. I have an honest love for the Geranium. Its dashing sunny colouring appeals to me, and if it would only behave itself when winter touches its leaves all would be well, but it gives in at once, leaving the Roses fresh and smiling as if the frost were merely the low temperature of a summer night. It is foolish for those readers who only grow a few July Roses to declare this to be exaggerated talk, for I have gathered flowers in December as sweet and dainty as anything seen in the garden in the fulness of summer. Till late in October the following varieties were not only in flower, but with countless buds to open, their future life depending of course upon the climate. As I notice several of your correspondents desire a small list I will give the names of what I consider the

### BEST TWELVE DWARF ROSES.

*Marie van Houtte* must head the list. I have it in all corners, but it never behaves badly anywhere, and its big, delicate flowers poised on strong stems are a joy in early morn when dewed with moisture and in the cool of the evening when distilling their sweetest perfumes. *Marie van Houtte* is sometimes dyed crimson almost with hot suns. Her cheeks then lose their delicacy, and it is only in autumn when the air is cooler and the growth less forced that the petals get firm and the colouring creamy white, with that margin of rose so characteristic of the flower. If I were asked to name one Rose, I mean a dwarf one, for the garden I should vote for *Marie van Houtte*.

*Caroline Testout*.—The more I see of this superb Rose the more devoted I become to its rare qualities. It has been the flower of flowers this year, and in my sunny garden the individual blossoms have surprised those who are accustomed to the giants of a show-board. It has a certain dash about it that charms one, and the big pinkish flowers hang so heavily on the stems that the burden is almost too great. But the stem makes a brave effort to hold up the fragrant burden, and therefore it is not a flower to flop about as if it were ashamed to

show its face. I have just come in from the garden, where I have planted eighteen more of this variety on an upper and very conspicuous border where failures are quickly apparent. There are always certain positions in a garden where failure *must not be*, else the whole place is affected.

*George Nabonnand*.—When Nabonnand gave to the world this Rose he brought joy and comfort to flower lovers in many lands. It is "unsurpassed as a bedding Rose," to quote a well-known catalogue, and its peerless rose colouring, mingled with yellow, and painted on large and beautifully shaped petals, is so beautiful that not a day passes without I pay my respects to a flower so lovely in all its attributes. It is strong, free, sweetly perfumed, and in my estimation should stand next to *Marie van Houtte*.

*Anne Olivier*, *Edith Gifford*, *Mme. Hoste*, *Maman Cochet*, and *White Maman Cochet* I shall not describe, because they are all so well known or should be. They all have those excellent qualities, vigour of growth and freedom of flowering, not during one month, but from June till late autumn.

*Viscountess Folkestone* must be named in my select twelve, but all Rose growers even on a small scale must favour this famous hybrid raised by Bennett, whose comparatively early death was a loss to the world of flowers. His great work of raising Hybrid Roses was in its infancy. I am mixing this with

*Princesse de Sagan*, which is a crimson Tea Rose, and not one spoilt by a magenta or purple shading. Its flowers are somewhat pointed, but their colouring is so intense and clear that from a distance the Rose is as conspicuous almost as a group of Henry Jacoby Geranium.

*Souvenir de Catherine Guillot*.—This has proved a thoroughly good Rose in my Thames Valley garden. Its flowers are given ungrudgingly, and their colouring is very rich—a coppery orange shade, with a touch of carmine.

*Mme. Chedane Guinoisseau*.—I esteem this for its canary-yellow colour, its handsome bud, and wealth of blossom. A bed of it has been exceptionally beautiful through the past autumn.

I give this list of twelve Roses because the Editor is asking for Rose experiences during the year that is fast passing away, and friends and acquaintances are perpetually asking the same question, so in the hope of saving labour, time, and stamps I send my note to you.

As I have headed this "A General Letter"

I may be permitted, I hope, to wander to other topics, and one is the

#### HORTICULTURAL HALL PLANS.

I suppose I must not criticise too freely, as the Editor does not desire any controversy. I agree with him in a measure, but I must express my feelings in respect to the building itself. I have already given as much as I can afford to the fund, and shall perhaps send another contribution, but the building as shown in the plans I can never admire. You likened the glass erection to the barrel of a railway station, but this is hard upon the station. Many a glass roof of a railway station is more beautiful in its proportions than the forthcoming exhibition hall of the society. A grand opportunity has been lost. An elaborate design with sculptured Floras and Pomonas pouring out the flowers and fruits over the earth is not to my liking, but many of the most beautiful and dignified buildings in the land are the simplest.

#### THE WHITE-STEMMED BRAMBLE.

I hope readers of THE GARDEN, and I am sure every subscriber diligently studies this weekly horticultural journal, will take note of the illustration and description of the White-stemmed Bramble (*Rubus biflorus*) given on page 379. It is, as you say, "A Winter Picture," and winter is not a season of desolation when the trees and shrubs that colour the woodland then are planted in variety and in groups. This Winter Bramble is a revelation. I have a small colony of it, and the white stems have just the effect in the grey light of a winter day as the waving flowers of Moon Daisy in late September. I notice your correspondent W. Dallimore writes of its beauty on a moonlight night, when its effect is strange and perhaps to certain minds "weird." Then in winter the crimson and yellow-barked Willows and the Dogwood add a ruddy colour note to the landscape. The stems reflect the cool light of the sun, and in the distance a crimson and yellow haze seems to have settled over the plantation. Those to whom winter is a season of gloom and sadness cannot know the trees and shrubs that are its chief glory. I speak not of the fretting of bare branches against the grey sky, but of the things that are full of colour and beauty, and that even flower and smell sweetly.

I am afraid this letter has exceeded all reasonable limits. I have never written to THE GARDEN before, but I feel guilty of selfishness. Are not all your readers workers in the garden, and is it not one's duty to try and help others to gain their gardening experience with a minimum of failures?

[We shall always welcome "Viator's" notes. It is of course our desire to make THE GARDEN as helpful as possible to all interested in horticulture, and the experience of amateurs is frequently of as much interest to the scientist as to the beginner.—ED.]

#### EDITOR'S TABLE.

##### CHRYSANTHEMUM GOLDEN SHEAF.

From Hampton, Mr. E. H. Jenkins writes: "The enclosed spray of Chrysanthemum is one of the hardest kinds I know; each year it flowers in mid-November. The variety was raised by myself some five years or so ago, and is the result of crossing the yellow variety of Mme. Desgrange and Admiral Symonds. The latter was the pollen parent, and this is also responsible for the excellent habit of Golden Sheaf. The height is rather less than 3 feet, and the plant has never been grown

anywhere but in the garden, save in its first year. As an effective garden plant the variety is extremely showy."

The flowers are a rich bright yellow, and very freely produced.

##### LAPAGERIA ALBA OUT OF DOORS.

From Oaklands, Dawlish, Devon, Mrs. A. Bayldon sends us a flower of *Lapageria alba* gathered out of doors. Mrs. Bayldon writes: "Among the flowers gathered to-day (November 20) was the enclosed *Lapageria*, gathered from a north wall, outside. Roses, Christmas Roses, Violets, and many varieties of Primroses and Chrysanthemums are fairly abundant, though we have had a terrible gale from the east for four days."

##### NOVEMBER FLOWERS IN SOMERSET.

Mr. J. Crook, Forde Abbey Gardens, Chard, sends an excellent gathering of bright flowers, including blooms of his strain of Border Polyanthus. During the mild weather and mid-November Mr. Crook could gather them in quantity. The flowers of *Salvia Bethelli* and *S. Pitcheri*, which were sent, were gathered from plants that have been in the open ground for two years. Spiraea Anthony Waterer was included also. The Polyanthus were the best of the gathering, however, and for this season very beautiful. The flowers were borne on long strong stems. Mr. Crook has evidently produced a good strain.

##### CHRYSANTHEMUM JULES LAGRAVERE.

Mr. Crook sends from Forde Abbey Gardens, Chard, Somerset, flowers of this excellent outdoor Chrysanthemum. The sender remarks: "I doubt if there is a better one for open air culture," and we agree with him. The flowers are not large, but of a warm glowing crimson colour, rich and beautiful in the cool light of a November day. It seems to defy frost, rain, and wind, and is the most cheerful flower of the open garden during the late months of the year.

##### A NEW ZONAL PELARGONIUM.

From The Gardens, Manor House, Heath, Mr. A. Chapman sends blooms of a new bedding zonal Pelargonium. It was raised by Mr. William Chapman two years ago. The flowers are very pretty, and we could imagine a bed filled with this variety making an excellent display. The blooms we have received are of a salmon-pink, much deeper in the centre than elsewhere. Mr. A. Chapman says in the summer the flowers are of a pretty salmon colour. He considers it to be worthy of something better than obscurity, and with him we are inclined to agree, especially as it is very free-flowering and is easily grown.

#### NOTES OF THE WEEK.

##### FORTHCOMING EVENTS.

December 6.—Meeting of the Société Française d'Horticulture de Londres.

December 9.—Royal Horticultural Society's meeting, Drill Hall, Buckingham Gate; House Dinner of the Horticultural Club, Hotel Windsor, 6 p.m.; Mr. Herbert E. Molyneux will open a discussion upon "Rose Growing near Large Towns."

December 11.—National Rose Society's annual meeting and dinner, Hotel Windsor.

December 15.—Meeting of the executive committee of the National Chrysanthemum Society.

December 16.—Annual meeting of the National Dahlia Society, Hotel Windsor.

**The New Horticultural Hall.**—Allow me to express my surprise at the plan and elevation selected for the new hall. In an undertaking of national importance, the very best design that can be obtained should be secured, and I venture to suggest that an open competition for architects would lead to that result. I offer no criticism upon the drawings referred to, but am convinced that better designs both for interior arrangement

and exterior effect would follow if competitive plans were prepared by expert architects, and might suggest that a prize or prizes should be awarded to the successful exhibitors.—JAMES L. WOOD, *Wood Green, N.*

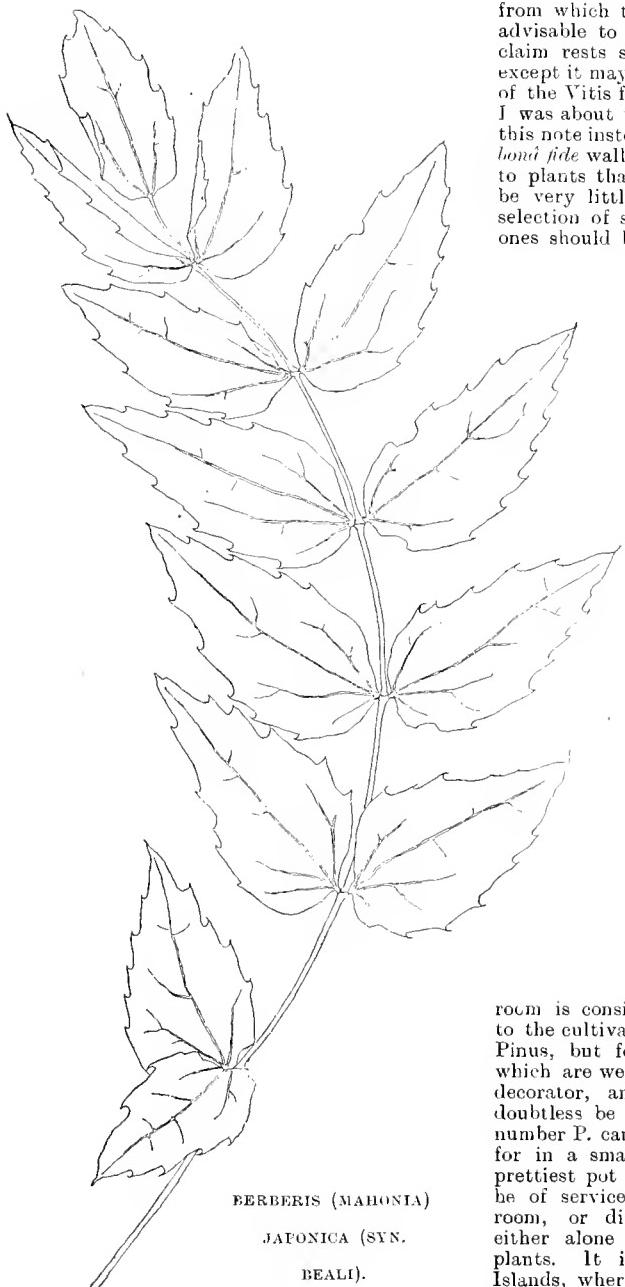

**Apple Rival.** In the note accompanying our illustration of this Apple, in last week's issue, Messrs. Clibran were stated to be the raisers. Mr. Charles Ross, Welford Park Gardens, Newbury, Berks, however, raised this variety, and from him Messrs. Clibran obtained the stock.

**Eomecon chionantha and Wulfenia carinthiaca.**—These two plants, while growing well with me, absolutely refuse to flower. I have seen recommendations as to the former, both for shady places and in sun, so possibly it is always uncertain. The latter plant I know is a very difficult one to flower anywhere. Possibly some of your readers may be able to state their experience with these plants, as they are both very desirable acquisitions I understand.—S. T. *Harethwaite, viii Ulverston.*

**Nerine Fothergillii.**—"L. M. R." Jersey, writes that "S. G. R., Spalding, may be interested to know that she has grown the *Nerine Fothergillii* with great success out of doors for the last two years. She planted them against the house wall, facing due south, and sheltered on either side by climbers. Last year from eighteen bulbs she had seven splendid spikes, and this year twelve: some with thirteen flowers and a glorious colour. The bulbs get thoroughly baked when they are planted in a little bed to themselves under a window, and beyond a little liquid when they began to show bloom have had no special attention."

I have heard many complain of being unable to get *Nerine Fothergillii* and varieties to flower satisfactorily. I may say that we had a grand display of them this autumn, grown in 5-inch, 6 inch, and 8-inch pots. We grow them on a shelf fastened to the back wall of a cool lean-to house near to the ventilators. During growth, which goes on all the winter, we give them very weak manure water. After they have completed their growth, we withhold water gradually and leave them on the same shelf, allowing the sun to shine directly on the pots and bulbs all the summer. This appears to be the secret of success. As they go out of flower they are placed on the shelf again. We avoid overpotting, and give water very carefully when growth commences.—JAMES R. HALL, *Fox Warren Grange, Cobham.*

**Chrysanthemums of rich colouring.**—Among the many excellent exhibits from trade growers at the recent show of the National Chrysanthemum Society, that from Mr. W. J. Godfrey was specially notable for flowers of the warmer shades of colour. This grower may be justly proud of his introductions of the past season, as they embrace many of the best varieties now in commerce. Superb is Sensation, a very large bloom, with flat and broad petals of great substance, deep orange-yellow colour, tinted and suffused a reddish chestnut; the flowers are very weighty and invaluable in severe competition. Godfrey's Triumph is remarkable for its rich crimson colour, and is a useful flower when associated with suitable varieties on the show stands. The carmine-crimson colouring of Godfrey's Pride and its golden reverse stamps this handsome Japanese bloom as of the first importance for exhibition. Both on Mr. Godfrey's stand and in numerous exhibits throughout the show this variety was frequently seen. A flower in form somewhat similar to the last named is Exmouth Crimson; the rich crimson-lake colour on the inside of the fairly broad florets, and the equally rich golden reverse, place this in the front rank of exhibition varieties. The inside colouring of Godfrey's Masterpiece was more apparent than in several of the others. This is a brilliant Indian red, with a golden reverse; the flowers are large, spreading, and very weighty. Bessie Godfrey is another from the same source; the colour is a pleasing creamy yellow. The flowers may be briefly described as a vastly improved Mme. Von Andie, and the plant is more easily grown.—D. B. CRANE.

BERBERIS (MAHONIA)

JAPONICA (SYN.)

BEALI.

**Plum Reine Claude Comte de Atthems Gage.**—This fine Plum is also known as d'Athan Gage, and in Messrs. George Bunyard and Co.'s catalogue it is described as "a delicious late dessert Plum, bearing very freely, and highly recommended." Mr. S. T. Wright, the superintendent of the Royal Horticultural Society's Gardens at Chiswick, considers it to be the very finest dessert Plum for growing in the open as a bush or standard or against a wall. For the past seven years it has never failed to produce a crop at Chiswick, and this year, when there was a failure with many sorts of Plums in the open, this variety, grown as a bush, carried a great crop, while other Gage Plums were failures. It is one of the principal varieties grown by Mr. James Hudson for an early crop in the gardens at Gunnersbury House.—R. DEAN.

**Wall plants.**—When a considerable amount of wall space has to be covered some little care is required in the selection of plants suitable for the purpose and to secure flowers through several months of the year; also with reference to deciduous and evergreen plants, so as to manage that no continuous stretch of wall shall be bare for any length of time. There are many good things

from which the selection can be made; it is not advisable to plant any species or variety whose claim rests solely on the beauty of its foliage, except it may be *Ampelopsis Veitchii*, one or two of the *Vitis* family, and the variegated Buckthorn. I was about to write climbers as the heading of this note instead of wall plants, but there are few *boni fide* wall climbers, and if one were restricted to plants that require no fastening there would be very little variety. Referring again to the selection of suitable plants, very strong growing ones should be omitted if wall space is limited;

*Wistaria sinensis*, for instance, must have plenty of room. We have a plant here covering nearly 2,000 square feet of wall, and a grand sight it is when in flower. This is, perhaps, too much space to allow any one plant, yet there is always a feeling against interfering with grand old specimens so long as they retain health and vigour. The training of wall plants is not always conducted on lines likely to show them to the best advantage. I have seen, for instance, such things as *Ceanothus*, *Escallonia*, and *Choisya ternata* trained and tied in with severe regularity. This is a mistake; it is far better to secure them to the wall and then let them have their own way as much as possible, avoiding encroachment on walks or other plants that may be in the immediate vicinity. Most wall plants like a fairly heavy soil and a deep tilth, and the time of pruning will vary with the different species. Some must be pruned in the winter months, others after the flowering season is over. I should like soon to give a list of the best things on our old walls.—E. BURRELL, Esher.

**Pinus canariensis.**—In

most establishments house

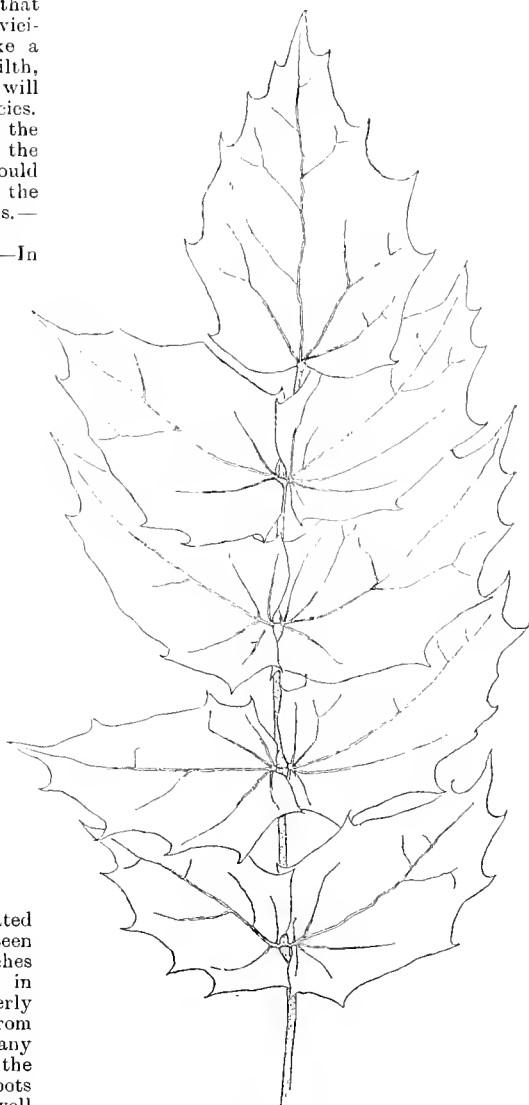

room is considered too valuable to devote to the cultivation of the tender species of *Pinus*, but for all that there are a few which are well worth the attention of the decorator, and if better known would doubtless be extremely popular. Of this number *P. canariensis* is a worthy example, for in a small state it forms one of the prettiest pot plants imaginable, and would be of service alike for the conservatory, room, or dinner-table decoration, used either alone or grouped with flowering plants. It is a native of the Canary Islands, where it is found at an elevation of from 5,000 feet to 7,000 feet. It is said to have been introduced about 1759 into English gardens, but through not being hardy it has many times dropped out of cultivation, and has had to be reintroduced. In a state of Nature it is said to grow to a height of 70 feet. The fully-developed leaves are in threes, 7 inches or so long and drooping, the cones 5 inches to 6 inches long, and upwards of  $2\frac{1}{2}$  inches wide. It is, however, before the leaves assume their true character that they are prettiest, and that is during the first three years of plant life. In this stage the leaves are 3 inches to 4 inches long, borne singly, densely covering the stem from the roots upwards, and of a beautiful glaucous hue. If cultivated in a warm greenhouse plants twelve to eighteen months old from seeds will range from 12 inches to 18 inches in height, and may be grown in 4-inch or 5-inch pots. These plants if properly cultivated will be well clothed with leaves from the pot to the apex of the stem, and in many instances side branches will be borne, as after the plants have become established in their first pots they are of little trouble. The species is well worthy a trial.—W. DALLIMORE.

**The Fruiterers' Company.**—The clerk to the Fruiterers' Company writes that Mr. Lewis Castle's prize essay on "Gathering, preparing, packing, and profitably disposing of home-grown fruit and vegetables by cottagers and others with small holdings," will be published by the company at a nominal price, and it is hoped and believed that it will form a valuable and useful manual on the subject with which it deals.

## TREES AND SHRUBS FOR ENGLISH GARDENS.

### TWO GOOD KINDS OF BERBERIS.

**M**ANY variable kinds of *Berberis* are very ornamental in our gardens, some as flowering plants and others for their very handsome foliage. In the latter group two of the best are *B. nepalensis*, from Northern India, and *B. japonica*, from China and Japan. The last-named kind is very often met with in southern gardens under the name of *B. Beali*, or even as *B. intermedia*, and its leaflets often take on the most brilliant of yellow or orange-red and scarlet tints late in

BERBERIS (MAHONIA) NEPALENSIS

autumn and winter. The two kinds are quite different and distinct, although for some reason or other they are very frequently confused together in both nurseries and private gardens,

*B. nepalensis*.—This forms a dense bush often 6 feet to 8 feet high in sheltered and half-shady places, its large dark green leaves showing a marked deflection from the stem, especially towards the base of the plant. The leaves vary in length from 12 inches to 26 inches, having seven to nine pairs of leaflets, which are quite separate from each other on the stem, and not imbricated or overlapping as in *B. japonica*. The tone of leaf-green is also very much darker than in the last-named species, and the venation is much more marked or distinctly to be seen. The variety called *B. intermedia* is more like *B. japonica*, but may possibly be a garden hybrid or seedling intermediate between *B. nepalensis* and *B. japonica*, its much shorter rounded leaflets being imbricate at their bases, and their venation more obscure than in *B. nepalensis* type.

*B. japonica* (syn. *B. Bealii*).—This is an erect shrub of lax habit, its tallest stems rarely exceeding 5 feet or 6 feet in height. The leaflets are only about half as long as those of *B. nepalensis*, more hastate at their bases, and overlapping so as to cover the leaf-stalk from above in a marked degree. Instead of being coarsely serrated with sixteen to twenty spiny serratures, as in *B. nepalensis*, each leaflet has only five to seven much coarser and stronger spines, somewhat like those of *Ilex cornuta* in general appearance. Its leaves are of a yellowish or Olive green above and of a pale Apple green hue beneath, while the nodal thickenings whence the leaflets spring are much less well marked than in *B. nepalensis*. *B. japonica* often assumes very bright colours in autumn and winter, whereas *B. nepalensis* very rarely or never does so. Both species are very handsome as seen growing on rich warm soils in the south and west of England and in Ireland, but of the two *B. nepalensis* is by far the rarest and most effective of the two.

Other rare and beautiful hardy evergreen Berberis are *B. nervosa*, or *B. glimacea*, from North America, and *B. fascicularis* from New Spain, a very handsome wall shrub with densely clustered Fern-like foliage. All these and several other evergreen large-leaved species were formerly included in a special genus (*Mahonia*), but are now placed under *Berberis* by the best authorities.

Dublin.

F. W. BURBIDGE.

## ROUND ABOUT A GARDEN.

### THE NEW AND THE OLD.

If we had no pretty British wild flowers with pleasant old-world names, there would be less reason to complain that our gardens contain only acclimatised exotics or "florists' flowers"—monstrosities from the naturalist's point of view—with terrible double titles of mongrel Latin and Greek mixed with German, French, and English. If a new and striking flower should be placed on the market next year called *Hucuspocus* Mrs. Ponsonby de Tompkins, we should all hasten to possess it according to our means and show it proudly to our friends. But there would not be much poetry in the invitation, "Come into the garden, Maude, and look at *Hucuspocus* Mrs. Ponsonby de Tompkins."

### FLOWERS OF FASHION.

It is this passion for fashionable novelties—a passion which characterises almost every phase of modern existence, and has relegated the cultivation of homely comfort in life to

remote country places—which prevents us from enjoying our gardens as our grandparents used to enjoy theirs. The owner of a modern garden, unless he be a scientific florist himself, can never feel at home in his garden. He is surrounded by beauties; but most are comparative strangers to him, and of many he cannot remember the names. They are fashionable and expensive, and undeniably handsome; but so are the contents of a West End shop window, whether you see them draped on dummies or displayed later upon the living article at a garden party. Yet there are still men who feel happier among their own familiar friends in simpler clothing; and the parallel would hold good in the garden if we did not allow our hired gardeners to drive thence all the simple old flowers that our fathers loved and called by pet names which were familiar to us all in nursery days.

### SOME SHOWY WILD FLOWERS.

Native British wild flowers especially have been forsaken, yet there is no part of a garden which can give you more pleasure than a real wild corner where you may see growing in natural luxuriance together all the wild charms of many a country ramble and all the flowers that grace the poetry of the past. Nor need such a corner be at all jingly or devoid of colour. No exotic shrubs can be more brilliant than the British Broom and Furze—the latter unequalled, too, for fragrance and often blooming in midwinter—while the dwarf Furze gilds the ground in autumn in happy contrast with the pinks and purples of Heath and Heather. Amid these the Harebell, properly encouraged, will make patches and pools of blue; while tall spikes of Foxglove, lesser spikes of Moth-Mullein, vivid purple-blue tufts of Bugloss, mauve and blue Scabious, Campions (red and white), Golden Archangel, blue Cornflower, scarlet and pale Poppies, Wild Wallflower, brilliant yellow Corn Marigold, and a host of other common British plants will, if you wish it, give you a blaze of colour bright as any "flower-bed" need be.

### NATIVE BULBS.

Now need what the gardener would call "the bulb section" be absent. The Wild Daffodil, Snowdrop, Winter Aconite, and Bluebell—as the Wild Hyacinth is best called, so long as you keep the good old English Harebell as the name of the so-called Bluebell of Scotland—are good enough flowers for any purpose; and when you see their gracious clusters richly starrng the "wild corner" of the garden in early spring, and recalling the charms of the woods and meadows of their origin, you enjoy, I think, a pleasure equal to any that comes from contemplating the inflorescence of your newest three guinea bulbs, named after some general in the South African war. And apart from pleasant associations of pretty English scenery, can anything be more beautiful in spring than a bank of Primroses or clustered Wood Anemones in the shade? And in autumn you can have the Meadow Saffron and the Autumn Bluebell tufting the sward with purple and azure.

### TENANTS OF THE WILD CORNER.

But the real joy of the wild garden lies in its less conspicuous treasures. A collection of wild British Orchids—the Bee Orchis, Butterlfy Orchis, Man Orchis, the common Spotted Orchis, and Marsh Orchis, with their many-shaded spikes from almost white through crimson to dark purple, or even the quaint green Twablade—gives a delightful interest to one nook. In another you may have the Fritillary's netted bells, the Pasque Flower's

curious blossoms, silky without and deep purple-violet within, and the Pheasant's-eye Adonis, scarlet with a black centre. The common Star of Bethlehem may often be seen in gardens, but the far more beautiful drooping kind, sometimes called Angel's Tears by country folk, is seldom seen outside the shady wild glades where it dwells. This should be a welcome fixture in the wild corner; where, of course, all of the five British Violets would find a home. There, too, Ferns of every British kind would be planted, revelling in the half shade of trees with the tall Rosebay and Scented Woodbine. On the dry slope Sweet Briar would flourish with the Furze and Heather, and, if a moist hollow could be contrived, Willow Herbs, Meadowsweet, St. John's Wort, and Purple Loosestrife might be clustered, as we see them sometimes in Nature's own wild "flower-beds." But it would be hopeless to enumerate literally—hundreds of quaint and pretty wild plants that one might bring together in the wild corner of a garden, each one perhaps reminiscent of happy rambles in the country, and the whole collectively affording interest and demanding some little touch of care every day in the year. To such a collection the joy of adding new treasures at all seasons never ends.

E. K. R.

## CHRYSANTHEMUMS.

### CHRYSANTHEMUM SHOWS

IT is a moot point whether, in spite of the fact that most autumn flower shows are chiefly devoted to the Chrysanthemum, there would not before now have been a material decline in popularity and in the attendance on the part of the public were not various other features introduced into them which helps to maintain interest. In the Chrysanthemum we have seen, and happily, too, an almost entire clearing away of specimen plants. They have from the first been generally plant abortions, evidences of misdirected energy. Now there is a growing lack of interest in the common boxed flowers, not only because so very flat and formal when seen in long lines, but also because now from year to year there is so little diversity in size, colour, or form of flowers. Raisers seem to have reached the full length of tether Nature has for them, as what may be called improvements in any features are practically non-existent. In cut blooms the introduction of vase classes has done much to recreate popularity, as the public like to see flowers of any description set up on long stems in vases, especially if a little other foliage be included. The more flowers so shown be included in exhibitions the better for them. There is the merit also that, whilst boxed flowers of necessity must have short stems, that renders them useless for decorative purposes after the show may be over, those on long stems in vases are capital for such a purpose, and may be made useful for some time later. Probably there are many gentlemen who feel that the sacrifice made of their flowers by having so many cut for exhibition is too great, especially as it is the finest and best that is thus removed.

Of other features at late autumn flower shows pot plants of diverse kinds prove very attractive, especially as they help to introduce so much variety as well as beauty into exhibitions. At the recent Kingston show we had numerous brilliantly flowered plants of Begonia Gloire de Lorraine, that visitors were greatly charmed with, also with double and single Chinese Primroses (some superbly grown and flowered), Bouvardias, any other plants in flower, table plants, miscellaneous groups, fine fruit and vegetables, and, not least, pretty table decorative efforts by ladies, and bouquets, which create so much interest. It is these things at shows that enable visitors to see

IBERIS SEMPERVIRENS VAR. GARRETTIANA IN THE ROCK GARDEN, KEW.

that horticulture is not solely devoted to the Chrysanthemum, and that there are many far more easily grown products that merit all encouragement, and, in many respects, may be far more pleasing than are tall, ungainly plants. Executives of these autumn exhibitions are wise in encouraging all descriptions of autumn or winter products which help to beautify gardens, greenhouses, or have enduring uses.

A. D.

in the mixed border. This variety lasts long in flower, and is in every way one of our best border plants.

A. E. THATCHER.  
*Aldenham House Gardens, Elstree.*

## IBERIS SEMPERVIRENS.

AMONG the many ornamental plants of the natural order Cruciferae that bloom in spring and early summer one of the most useful is the Evergreen Candytuft, with its masses of pure white flowers and dark green foliage. It is equally good in the front edge of the flower border or among boulders in the rock garden. It is also a most accommodating plant, for it is one of those that for several years can be left untouched, the neat healthy-looking cushion of dark green leaves only spreading a little wider year by year. *I. s. garrettiana* differs from the type in having longer racemes and being more floriferous.

## COLCHICUMS AND CROCUSES GROWING DEEPER.

WITH regard to this question, introduced by Mr. F. A. Sturge in *THE GARDEN* of the 15th ult. (page 339), I think that a good deal depends upon the character of the soil and the depth at which the corms were originally planted. I have found in my light soil that some Colchicums have gone considerably deeper than when first planted, but that others, planted formerly at some depth, have practically maintained their original position. Crocuses, on the other hand, do not show this tendency, and I have no reason to think that *C. speciosus* acts differently from the others. In his "Monograph of the Genus *Crocus*" Mr. George Maw refers to the subject in connexion with seedling Crocuses, and says: "The seed, under natural conditions, germinates near the surface of

the ground, but the fully matured corm is rarely found at a less depth than 3 inches, and often occurs 4 inches or 5 inches deep. The small one year old corm is always found near the surface, and it is evident that in the annual process of reproduction it possesses some power of descending deeper into the ground. This would, however, seem inconsistent with the mode of reproduction in which the new corm is found on the summit of that which it replaces; but that such a power is possessed was strikingly illustrated in the above-named experiments on germination."

A diagram is given showing a string of empty corm tunics from near the surface, where the seeds germinated, to the actual corms at the bottom of the pot. Maw goes on to say: "The process of the descent of the corm from near the surface to the necessary depth is difficult of explanation, and it must be viewed as one of the many self-protective phenomena in plant life, the *modus operandi* of which we do not understand."

It may be mentioned, however, that *C. speciosus* is one of the few species of *Crocus* which produce their young corms at the base of the old. Is it not possible, however, that there may be some other cause present to account for the disappearance of *C. speciosus* in Mr. Sturge's garden? It is well known that mice are very destructive to Crocuses in some places, and also, though hardly likely to be the case with your correspondent, that grass is often cut too early, with the result that the foliage of the bulbs grown among it is not ripened enough. It cannot be denied, however, that there are some bulbs which have a tendency, at least in some soils, to bury themselves so deeply as eventually to be unable to send their leaves to the surface, or it may be to prevent them from flowering. I have known this occur with *Lilium longiflorum* in my own and other gardens, and *Erythronium americanum* is another case in point. It will be observed that a reference to the subject occurred at the meeting of the scientific committee of the Royal Horticultural Society on the 4th ult. I believe that the proper elucidation of the question would require long experiments under varied conditions of soil, and, it might be, of climate also.

S. ARNOTT.

## NOTES FROM PADSTOW.

A WALK through the grounds at Prideaux Place is always of interest. The shrubberies contain some remarkably fine examples. Here *Cotoneaster frigida* makes quite a tree fully 40 feet high, and the branches are weighed down with masses of scarlet berries. This species should be planted more often, for it is very attractive during the flowering season as well as in the autumn. Its white flowers are very freely produced in cymes. If the shrubs are required to fruit when young they should be severely pruned for a couple of seasons.

*Pittosporum undulatum* is in luxuriant growth; one specimen near the conservatory is quite 25 feet high, the black twiggy stems and shining undulated leaves are very striking. Near by is the finest *Griselinia littoralis* I have ever seen. It is fully 20 feet in height and as much through.

Mention must be made of the famous *Magnolia grandiflora* which grows up one side of the mansion. At this late date it has open flowers and buds in plenty. *Garrya elliptica*, so common and useful in and around London, is such a rarity in North Cornwall that its presence was greeted with welcome surprise. Cornwall is, *par excellence*, the place for *Benthamia fragifera*. At Prideaux Place it is an immense shrub; one large specimen flanking a courtyard was bright with fruits, and seedlings spring up amongst the cobble stones at its base. In the dell I noted fine clumps of the variegated New Zealand Flax (*Phormium tenax*). Being so near the sea conifers do not thrive, the salt spray proving very injurious to them; but, as may be expected, *Escallonia*s do remarkably well, the comparatively rare *E. floribunda* (syn. *E. montevidensis*) is represented by a fine example. Mr. Brown remarked that cuttings of this species root with difficulty.

The flower garden was still bright with *Lobelia cardinalis*, *Caenias* in variety, and 5 feet high pillars

## NOTES ON HARDY PLANTS

## CROCUS ASTURICUS ATROPURPUREUS.

ONE was glad to see the note by Mr. Weaver on this Crocus in *THE GARDEN* of the 15th ult., as well as the recent interesting and useful article by Mr. Jenkins on the autumn-flowering species in Messrs. Barr's nursery. I have already said so much in *THE GARDEN* about these Crocus species and their value that it is pleasant to see some others again referring to them in the terms of praise they deserve. For the alpine garden in particular, where practically all the flowers are perennial and the greater number early-flowering, these autumn Crocuses are simply invaluable. Even in a disappointing autumn, as this has been here, their worth is beyond question. The little dark purple *C. asturicus atropurpureus* is one of the most distinct and one of the best for the rockery or border.

Its colour reminds one of the dark purple Dutch Crocuses of spring, though the flower is much smaller. Mr. Weaver's remark that it is "quite

of pink Ivy-leaf Pelargoniums. The kitchen garden is well stocked and in good order. Amongst Peaches Ainsden June and Sea Eagle are thought highly of. The kinds of Apples which do best are Bramley's Seedling, Stone's Apple, Devonshire Quarrenden, Northern Greening, Adam's Pearmain, Cox's Orange, and Ribston Pippin. The foliage of these two latter kinds suffered badly this year from the cold spring winds. Mr. Brown, the capable gardener at Prideaux Place, is probably the best Grape grower in North Cornwall. In the late vineeries a splendid lot of Grapes were hanging. Especially fine were Mrs. Pearson, Black Alicante, Mrs. Prince, and the old Barbarossa. The ripening foliage of this variety was brilliant in colour.

An up-to-date collection of Chrysanthemums is housed in the early vineeries. They are a good healthy lot of plants, each bearing five or six very good blooms, this method of growing having been found to produce more useful results than when fewer and larger flowers are obtained.

A. C. BARTLETT.

## NOTES FROM SWANSWICK.

### SINGLE CHRYSANTHEMUMS.

It is claimed by the raiser, or the vendor, or both, for Edith Pagram that it is the best single Chrysanthemum ever sent out, and certainly, for outdoor use, this variety is very charming. It must not be judged by the first blossoms, which, in this garden at all events, opened slowly and of a bad colour; later on the colour warmed up, becoming a very pleasing bright rose, streaked with a lighter shade. The flowers are very large, of great substance, perfectly round, with a showy centre, and well above the foliage. The habit is stiff and sturdily upstanding, and the plant and flowers resisted day after day a fine soaking rain that reduced some of the Japanese to pulp and miserable abasement. This season has been an excellent test of endurance for hardy Chrysanthemums. First they were seared by bitter east winds, which for the past few years have been prevalent here all through April and May; then, for a very short time, they were dried and baked; then came incessant drizzling rain, and grey weeks without a ray of sun. Lemon Queen stands the wet famously, and I shall give this type of flower, with the singles, preference over thin narrow-petalled sorts in future. The narrow-petalled whites, especially, that turn pink at the back the moment they get really wet, and afterwards hang determinedly head downwards, are useless in rainy seasons like this. Helianthus Miss Mellish is one of those things as easy to introduce, and as hard to get rid of, as a good-looking governess in a house full of grown-up sons. The running power of this plant surely exceed those of the rest of the family, none of whom are backward in increase. A market for bits of root at half-a-crown a dozen ought to make a quick and easy fortune for people who advertise it.

I am pleased to see praise of Linaria alpina, for a small tuft of it in our old garden was becoming a very charming thing when we left it. It had been planted on the top of a bank consisting of absolutely nothing but sticky yellow gravel with stones, and was spreading rapidly, perfectly at home in this unpromising medium. The flowers showed up with a very sweet gaiety and much freshness against the deep green leathery leaves, in their neat tufted spread, and their colour, bright lilac and orange, was delightful.

Does anyone know a Moss Rose called Emmeline? I have searched for its description in vain, and as I have become possessed of six bushes I should like to know whether it is of

any value. Another Rose I am desirous of tracing to its source and taking up the character of is Chapeau de Napoleon; and yet another, Fins IX., both, I believe, being Hybrid Perpetuals. It seems a pity that

### FUCHSIAS,

as indoor plants, have gone so much out of vogue. They—or rather the modern or improved forms—are really very beautiful, much more so than many plants that give a great deal more trouble. Mrs. Rundle—a somewhat long-flowered variety, in two shades of red—is an everlasting bloomer, and very pleasing in colour. It began to flower here in June, and went on until October without the least cessation; it then took a short rest, which might have been due to some error of treatment, but by October 20 it was in full beauty again, and is so still, though the first frost of the season—November 19—has just made itself severely felt in the cold glass gallery where the Fuchsias are kept. Wave of Life, though old-fashioned, is very pretty. It makes neat bushes, and its rather small single blue and red flowers are most profusely produced, and show up well against the gay foliage, the young leaves being of a golden colour. It, however, is not so perpetual as Mrs. Rundle. The Phenomenals are very massive, and Rose Phenomenal in particular, grown as a standard, is always admired, both for the size of its huge double flowers and for their colour—bright mauve corolla and cherry-red sepals. But there is nothing like the floriferousness in these that most of the singles and some smaller doubles possess. Achilles is a showy thing: E. Chopton is nearly as good in size as a Phenomenal, and much freer; and Rupert is extremely good, among the smaller singles, and especially for flowering as a compact little bush in a 5-inch pot. Small bush Fuchsias with round heads, 9 inches or so high, make charming jardinière plants, and are now quite uncommon. No doubt there are many better Fuchsias than those mentioned, as there have been a good many new ones brought out; but all those cited are really worth growing.

M. L. W.

## THE FLOWER GARDEN.

### ALPINE SHRUBS IN THE ROCK GARDEN.

**S**HUBS coming under this heading are so numerous that I shall endeavour to give only a small selection of the most distinct, easily cultivated and adapted for the rock and alpine garden. These naturally inhabit either the cold Arctic or Antarctic regions, or are more often the survivors of the glacial flora still to be found on the high mountains of Europe and Asia. When transplanted to the plains with few exceptions they will preserve their character as dwarf shrubs suitable to the rock garden. With few exceptions they are easily grown, and if care is taken that only pot-grown and established specimens are procured and planted there need be no real difficulty with either species. It must of course be always understood that certain plants being partial to certain soils would probably not succeed if planted in those of entirely different composition. Thus a Heath (Erica) would never grow in limestone, or a plant partial to limestone would not succeed in peat.

*Alnus viridis*.—A slow-growing plant typical of the high Alps, locally common on the Alps of lower Austria. The leaves are pointed, ovate, glabrous above and pubescent beneath.

*Arctostaphylos alpina*.—A close-growing, deciduous shrub of creeping habit. The leaves are small, slightly serrated, netted and wrinkled,

while the berries are black. On the Alps this species usually grows in high altitudes in peaty soil mostly damp, but I have more than once found it in sandy or gravelly soil. Collected plants are not always successfully grown; they are better when raised from seeds or cuttings.

*A. Uva-ursi* is a well known and pretty evergreen of fairly quick-growing habit. The plant is trailing, and has thick and smooth leaves. The flowers are pretty, rosy or white, urn-shaped, and in the autumn and winter are followed by berry-like fruits, red or coral red. Fairly common on the Alps and on most mountains of Europe, also Great Britain.

*Azalea procumbens* (*Loiseleuria procumbens*).—One of the most desirable of alpine shrubs. The plant only attains a height of a few inches, and forms a much branched tufted shrub with small evergreen leaves. The pretty flowers are flesh or rose-coloured, bell-shaped. It grows best in peaty soil and in a fairly moist position. It is a native of mountains of both Europe and North America.

*Chiogenes hispidula*.—A little-known trailing shrub with almost thread-like woody stems and small ovate leaves, light green and smooth, quite evergreen; the branches are covered with small bristles. The flowers are small, white, and in the autumn the plants have white berries. It grows best in a half shady moist position in peaty soil. North America on the Alleghany Mountains.

*Epigaea repens*.—This is one of the prettiest and most distinct of dwarf shrubs. Though it is neither a high alpine nor an Arctic plant, it is sufficiently difficult to manage, and while some grow it with ease and to the highest perfection, in other cases it fails entirely. It is of distinct trailing growth, and the wood is hard and quite wiry, rough, and covered with rusty hairs. The leaves are rounded or heart-shaped. The pretty flowers produced in terminal or axillary clusters, are salver-shaped, white, or more often flesh or rose-coloured, and deliciously scented, hence the North American name Mayflower. It is a common North American plant, growing on sandy plains or hills, either in the half shade of Pine woods or quite in the open. Of the thousands of plants imported every year only a small proportion survive. It is advisable to procure only well-established pot-grown plants, and if once the Epigaea is well established and in a suitable spot not likely to be disturbed it will luxuriate and flower freely year after year. It is delightful among hardy plants and dwarf shrubs.

*Empetrum nigrum*.—This somewhat resembles Azalea procumbens, though it is not quite so pretty. It is an evergreen of creeping habit, with small, linear-oblong leaves. The flowers are inconspicuous, rose-coloured, and the fruit is black. Easily grown in peat and loam.

*Corema Conradii*.—Closely allied to Empetrum, with small leaves like those of Erica, and pretty purple flowers with conspicuous brown anthers. Easily grown in sandy soil among stones.

*Polygala Chamaturus*.—A pretty evergreen shrub or sub-shrub, with deep green elliptical leaves and yellowish or purplish rather showy flowers. Easily grown on rockwork or border in loam or peat, and is also a good pot plant.

*Rhamnus alpinus*.—A pretty evergreen dwarf shrub, with heart-shaped, elliptical leaves. Flowers small and greenish. On the Alps this shrub grows everywhere in the crevices and on rocks, and is difficult to collect. *R. pumila* is similar in every respect to the former species, but grows more like Ivy over boulders. The flowers are pure white.

*Rhodothamnus Chamaecistus*.—Though not always grown to perfection in the plains, this is undoubtedly one of the most handsome of alpine shrubs. On the Alps it is invariably found in altitudes of only a few thousand feet on moraines with little humus. It forms neat, compact and bushy tufts about 6 inches high, and has evergreen, light-coloured, elliptical, rather small leaves, covered with hairs. The flowers are somewhat bell-shaped, proportionately large, and rose-coloured; sometimes, however, deep purple or pure white.

*Rhododendron*.—Of these there are several suitable kinds; indeed, almost all the small-leaved, dwarf-growing Rhododendrons are more or less alpine. The best known are *R. ferrugineum*, growing according to position from 1 foot to 3 feet high, with ovate, evergreen leaves, ferruginous beneath, and terminal heads of purple, rose, or white flowers. Common on the Alps from 3,000 feet to 5,000 feet altitude. *R. hirsutum* has hairy leaves and rose-coloured flowers. Both these species are known under the name of Alpine Rose to the inhabitants of Switzerland. *R. kanschaticum* was, I believe, for the first time brought to notice by Dr. Regel, and figured splendidly in the "Gartenflora," but even now it is but very little known, although it must be counted among the most showy and distinct of dwarf or alpine Rhododendrons. It forms a neat bush of

peculiar wood or bark. The best of the species are *S. cAsia*, a dwarf bush with lanceolate glaucous green leaves; *S. sericea* or *S. glauca*, leaves lanceolate, silky, very dwarf; *S. reticulata*, leaves large, glandular, and netted, pale green, of prostrate, slow-growing habit; and *S. serpyllifolia*, perhaps the smallest of *Salix*, of slow and close-growing habit.

(C. REUTHE.)

### FLOWERS IN THE KITCHEN GARDEN.

A GLANCE at the accompanying illustration of a herbaceous border in the kitchen garden, Trensham Vale, Farnham, Surrey, the home of Mr. Spencer Castle, shows how the more commonplace parts of a garden may be made beautiful with simple flowers. Mr. W. Harding, the gardener, writes that the Pink

forming such a beautiful edging to the border is the variety Her Majesty. The other hardy herbaceous plants which fill the border have only been planted two years, and when the photograph was taken in July last the border, Mr. Castle writes, was a beautiful sight.

FLOWER BORDER IN KITCHEN GARDEN (TRENSHAM VALE, FARNHAM, SURREY).  
THE EDGING IS HER MAJESTY PINK.

about 6 inches to 12 inches in height, and has ovate, hairy leaves, and the flowers are produced on single stems, not in clusters or heads as most of the other species, while they are large, and rosy or rosy purple in colour. It is easily grown in peat, leaf-mould, or even sand, but must have a fair amount of moisture in sunny or partially shady position, one of the most northerly species of Rhododendrons, which, however, does admirably in the moist English climate.

*Rubus arcticus*.—A pretty dwarf-growing plant, with a somewhat puny stem, heart-shaped leaves, and large, rose-coloured flowers. It is easily grown in a fairly moist position in loam and leaf-mould.

*Salix*.—These alpine Willows are grown not only on account of their handsome foliage, such as in *S. reticulata*, but quite as often for their

handsomer blossoms than the type, being of a brilliant scarlet profusely spotted with crimson. *T. P. albiflora* has a white ground. To grow Tigridias successfully the bulbs require an open and rich soil, and the site chosen for them should not be where the sun shines upon them the whole day long, but it should be a partially shaded position, for I find that although two or three hours' sunshine during the day assists materially in expanding the flowers, yet the growth is far freer when the plots are in a partially shaded position—such as the Gladiolus revels in will suit the Tigridia. Without a doubt a cool rooting medium suits these plants, with two or three hours' sunshine playing upon them during the day. A heavy mulch of decayed Mushroom-bed manure will be of immense benefit in conserving moisture about their roots during spring

and summer when growth is active. The foliage resembles that of Montbretias, and like them dies down in the autumn of each year, when they should be lifted and placed in a shed or cold frame to complete their ripening, when the bulbs may be stored in sand for the winter months and kept away from frost. Replanting may be performed in March in the position they are to occupy for flowering, or the bulbs may be potted up in February and gently started into growth under glass, afterwards hardening them off before planting out. Groups or colonies of Tigridias, judiciously planted about the grounds, will produce a charming effect, the individual blossoms vieing with many of our most beautiful Orchids. Tigridias may be increased by seeds or offsets, the first-named mode being very interesting. The seed may be sown, when ripe, in summer, and the young plants may remain where sown until the following spring, when they may be dibbled into a rich border and grown on freely. If well grown the bulbs will produce flowers in the third year after sowing.

Stoneleigh Abbey Gardens.

H. T. M.

### WALL GARDENING.

#### THE WALL GARDEN IN NOVEMBER.

FLOWERS in the wall garden during November, especially towards the end of the month, after the severe frost we have been experiencing all over the country, are scarce indeed. No flowers, in fact, can be said to have opened during the month, but those still blooming are either stragglers, which were planted late, or strong plants which are flowering the second time, and are as yet unharmed by the frosty weather. Antirrhinums and Pentstemons are still making a fair show of bloom on the top of a wall where they have plenty of soil and light. *Linaria anticaria*, with its white blossoms and dark maroon under lip, is still in evidence. The double form of *Arabis alpina*, with its large pure white flowers, is in full bloom for a second time at Exeter, and even *Corydalis ochroleuca*, *Polygonum vaccinifolium*, and *Erigeron glabellus* are still attractive with a few belated blossoms, but they are the exception rather than the rule, and it is no use to get away from the fact that flowers for this year are a thing of the past; but in a wall garden carefully arranged with a view to successive effects care would have been taken to ensure attractions even during winter. Not in the shape of flowers, perhaps, because these would be possible only under exceptional conditions, but in the matter of colour of foliage much more might be done than is generally attempted. Some wall plants bear foliage of exceptional brightness of colour, which lasts even longer than the flowers, and I will enumerate a few which strike me as being particularly worthy of notice.

*Plumbago Larpente* has passed out of bloom, but its bright green foliage is just now (the last week in November) very showy. Some of the leaves are flaked or blotched with scarlet; some retain a bright green centre, but have a scarlet margin; while others have turned scarlet or reddish bronze all over, and where here and there a few of the bright cobalt-blue blossoms are still lingering, the effect is doubly striking by way of contrast.

*Saxifraga Geum* is perhaps more attractive now than at any other time by reason of the vivid contrast in its leaves. Some of these are st. bright green, while others are tipped with a f. scarlet, which is most welcome at this dull time o. the year.

*Sedum spurium*, with its pink flowers, and its more deeply-coloured variety, *Sedum sibiricum*, have finished blooming, but their leaves are turning a red-bronze colour, not so bright, perhaps, as the last-mentioned *Saxifraga Geum*, but, nevertheless, attractive.

*Arenaria cespitosa aurea* bloomed early in the year, but for a bright golden-yellow colour, most showy at this time, nothing can surpass it. It is suitable for wall or rock gardens alike, and is easily grown and propagated by division.

*Mesembryanthemum uncinatum* is probably the hardiest of its tribe, and, though its small pink blossoms no longer delight our eyes, its peculiarly jointed, glaucous stems and foliage are nevertheless attractive, especially if contrasted against foliage of a brighter hue.

*Sempervivum triste* is dark in foliage all the season, but just now it is perhaps at its best, its rosettes of fleshy leaves showing a dark reddish brown colour, which makes a particularly fine background for plants of lighter foliage.

*Alyssum spinosum*, with its fine silvery white foliage, makes an excellent companion to the former, both plants gain in effect by the contrast with the other. The white flowers of this Alyssum have long passed away, but its foliage, which lasts all the winter, more than makes up for the loss.

*Sedum spathulifolium* must also be mentioned as an attractive plant for winter effect. Its beautiful glaucous foliage is handsome at all times; when the plant is in bloom it makes a fine background to the blossoms, but now, after the frost, the leaves have become margined with vivid scarlet, which still further enhances its value as a decorative plant.

*Sedum mitchellianum*, too, has turned scarlet in its leaves and looks most cheerful.

*Mühlenbeckia nana* differs greatly from that vigorous grower *Mühlenbeckia complexa*. While the latter is a rampant climber, the dwarf form is uncommonly neat, clinging close to the stones and covering them with a minute carpet of a bronzy brown colour.

Elmside, Exeter.

## THE ROSE GARDEN.

### ROSE WHITE PET (POLYANTHA)

FOR massing this Rose is well adapted, being then seen to much better advantage than when planted in twos and threes. It is perfectly hardy with us, and is also extremely floriferous, being at its best towards the end of June and the first week in July, with occasional bursts of flower in the autumn. For some years past now I have adopted the non-pruning system, with good results. All that is done is to cut away the old flower-trusses and any dead wood. By following this plan our bed of it has grown into a dense mass nearly 5 feet in height. A surface-dressing of manure is given in the spring,

being sometimes forked in; then, if any shoots need regulating by means of pegs to equalise the growth, they are attended to. Being quite a smooth-leaved Rose it does not show the deposits of blacks for any length of time, as the rains wash the foliage clean. Perle d'Or can be grown under similar conditions, and, like the preceding, it is greatly improved thereby—that is from the decorative point of view. It is a fitting companion to White Pet, being in addition a more profuse autumnal Rose. I consider that by adopting the non-pruning principle the constitution of these Roses is enhanced and their longevity ensured.

GUNNERSBURY, ACTON. J. HUDSON.

### ROSE G. NABONNAND.

I WAS surprised when looking through Messrs. W. Paul and Sons' Rose catalogue for 1902-1903 to come across the following note:—"The name of this Rose is sometimes erroneously written George

be very dry no other attention is necessary. In a cut state this Rose is also valuable, belonging no doubt to the Polyantha group. Its culture may be briefly stated. Sow the seed early in the year in a gentle heat, pot on into 3-inch pots when ready, and plant in the open in April. Messrs. Carter are to be congratulated on raising this Rose, which by the amateur may be grown to perfection. I have for several seasons past procured seed from them with the most satisfactory results.

*Aldenham House Gardens.* E. BECKETT.

### KAISERIN AUGUSTA VICTORIA AND ITS VARIETIES.

CONTINENTAL growers evidently set much store by this Rose, if we are to judge by the number of sports and seedlings, said to emanate from it, which are being distributed this season. Whether any of them are really acquisitions must remain to be proved. Here is the list culled from the catalogue of a leading grower:—

*Frau Peter Lambert* (Welter).—A pink-flowered K. A. Victoria said to be distinctly good. An exhibition Rose of the first rank, a good grower, and continuous bloomer.

*Frederic Hanus* (Welter).—A yellow K. A. Victoria, a robust grower, with very fine deep orange-yellow centre.

*Goldelse* (Hinter).—A dark golden-yellow sport from K. A. Victoria, large, full, and sweetly scented.

*Gustave Sobry* (Welter).—A cross between K. A. Victoria and Comte Chandon. Colour, reddish yellow shading to clear yellow. A vigorous and continuous

bloomer, with long pointed buds and large fragrant flowers.

*Perle von Goldelse* (Lambert).—A golden-yellow sport from K. A. Victoria, said to be very promising. From this list it would appear that there is quite a keen competition in the production of a really good yellow Kaiserin Augusta Victoria, and it is to be hoped that one or other of these recently announced varieties will supply this want.

A. R. G.

### CARTER'S ANNUAL ROSE.

AMONG the recent additions to our garden this is certainly one of the most noteworthy. I suppose the name Annual Rose was given on account of its flowering nine months after the seed is sown. As time advances it grows into a compact bush about 3 feet high and as much in width, and all the summer and autumn flower clusters are produced in the wildest profusion. The flowers vary considerably in colour. Some are pure white, while others are tinged with pink, and some a deep pink. On our clay soil here it succeeds well. Planted as isolated specimens or massed together in the shrubbery it forms an attractive group, and if room can be found in the rock garden it is a splendid subject. Little if any pruning is needed, and beyond an occasional watering should the weather

### SELECTIONS OF ROSES.

(Continued from page 328.)

#### NINE BEST BOURBON ROSES.

Now that autumnal blooming Roses are so much admired the sturdy Bourbons will attract even more attention than hitherto. They can be highly recommended for planting in somewhat bleak localities together with the best of the Hybrid Perpetuals. Nine of the best are:—

Acidalie, blush; Armosa or Hermosa, deep pink; Kronprinzessin Victoria, milk-white; Lorna Doone, carmine; Mme. Isaac Periere, rose; Mme. Pierre Oger, white, shaded lilac; Mrs. Paul, pinkish white; Queen, buff; Souvenir de Malmaison, flesh.

## SIX BEST HYBRID SWEET BRIARS.

The popularity of these delightful Roses shows no signs of diminishing. There is not perhaps sufficient individuality in some of the varieties, and if one selects six from the sixteen these would comprise all the most distinct. The following are recommended:—

Amy Robsart, rose; Anne of Geierstein, crimson; Brenda, peach; Flora McIvor, rosy white; Green Mantle, rich pink; Lady Penzance, copper.

## NINE BEST HYBRIDS OF ROSA WICHURIANA.

There are so many ways in which one may employ these lovely Roses that a somewhat large selection seems warranted. Doubtless raisers will obtain even more remarkable colours. The best nine are:—

Alberic Barbier, creamy white; Dorothy Perkins, soft pink; Gardenia, bright yellow; Jersey Beauty, yellowish white; Paul Transon, rose; Pink Roamer, pink; René André, saffron yellow; Ruby Queen, brilliant carmine; wichuriana rubra, bright red.

## AN ARTIST'S NOTE-BOOK.

## SMILAX ASPERA.

**A**LL who have lived or travelled in the region of the Mediterranean basin must be familiar with this graceful climbing plant, for its distribution is wide throughout that region, and its habit is so distinct that, except for one small Algerian Aristochia which somewhat resembles it, it is hardly likely to be confounded with any other plant.

It climbs mainly by the aid of the prickles on the stems, but the backs and edges of the leaves are also prickly, helping to sustain the plant as it scrambles over rocks and bushy growths. The form of the leaf, though usually that of a broad lance-head, with distinct shoulders, is extremely variable both in size and shape, for though usually of the broad lance-head pattern, it is sometimes like a wild Ivy or Convolvulus leaf. We have a drawing from life of one leaf as much as  $4\frac{1}{2}$  inches long by 4 inches wide, another where the breadth of 3 inches taken across the wide round shoulders exceeds by 1 inch its length of 2 inches. In this leaf, though the shoulders are so round and wide, the point of the leaf forms a nearly exactly equilateral triangle for the last three-quarters of an inch.

On this point Mr. Daniel Hanbury says in his "Pharmacographia": "The common Smilax aspera, L., of Southern Europe is a plant which presents such diversity of foliage, that if, like its congeners of tropical America, it were known only by a few leafy scraps preserved in herbaria, it would assuredly have been referred to several species."

This pretty plant bears an axillary spike of small fragrant whitish flowers, which are followed by a bunch of Red Currant-like fruit. The leaves are sometimes marbled or spotted with dull white markings. It is a plant that, though common, is always interesting and pleasant to see, and we may enjoy it in our home gardens against a warm wall in the southern counties.

Its near relations of the tropical regions of Central America and the West Indian Islands yield the sarsaparilla of medicine.

Smilax aspera, which is a true Smilax, is not to be confounded with the plant so-called in flower shops. This is not Smilax at all, but *Myrsiphyllum asparagooides*. The popular name Smilax for this plant originated in the United States, no doubt on account of some likeness of growth and habit. The name, though misleading and only of recent origin, seems to have become fixed in the language, and is another example, of which a few exist already, of the botanical name of one plant being used as the popular name of another.

RECOLLECTIONS

GARDEN.

"Will spring return  
And birds and lambs again be  
gay,  
And blossoms clothe the Hawthorn spray?"

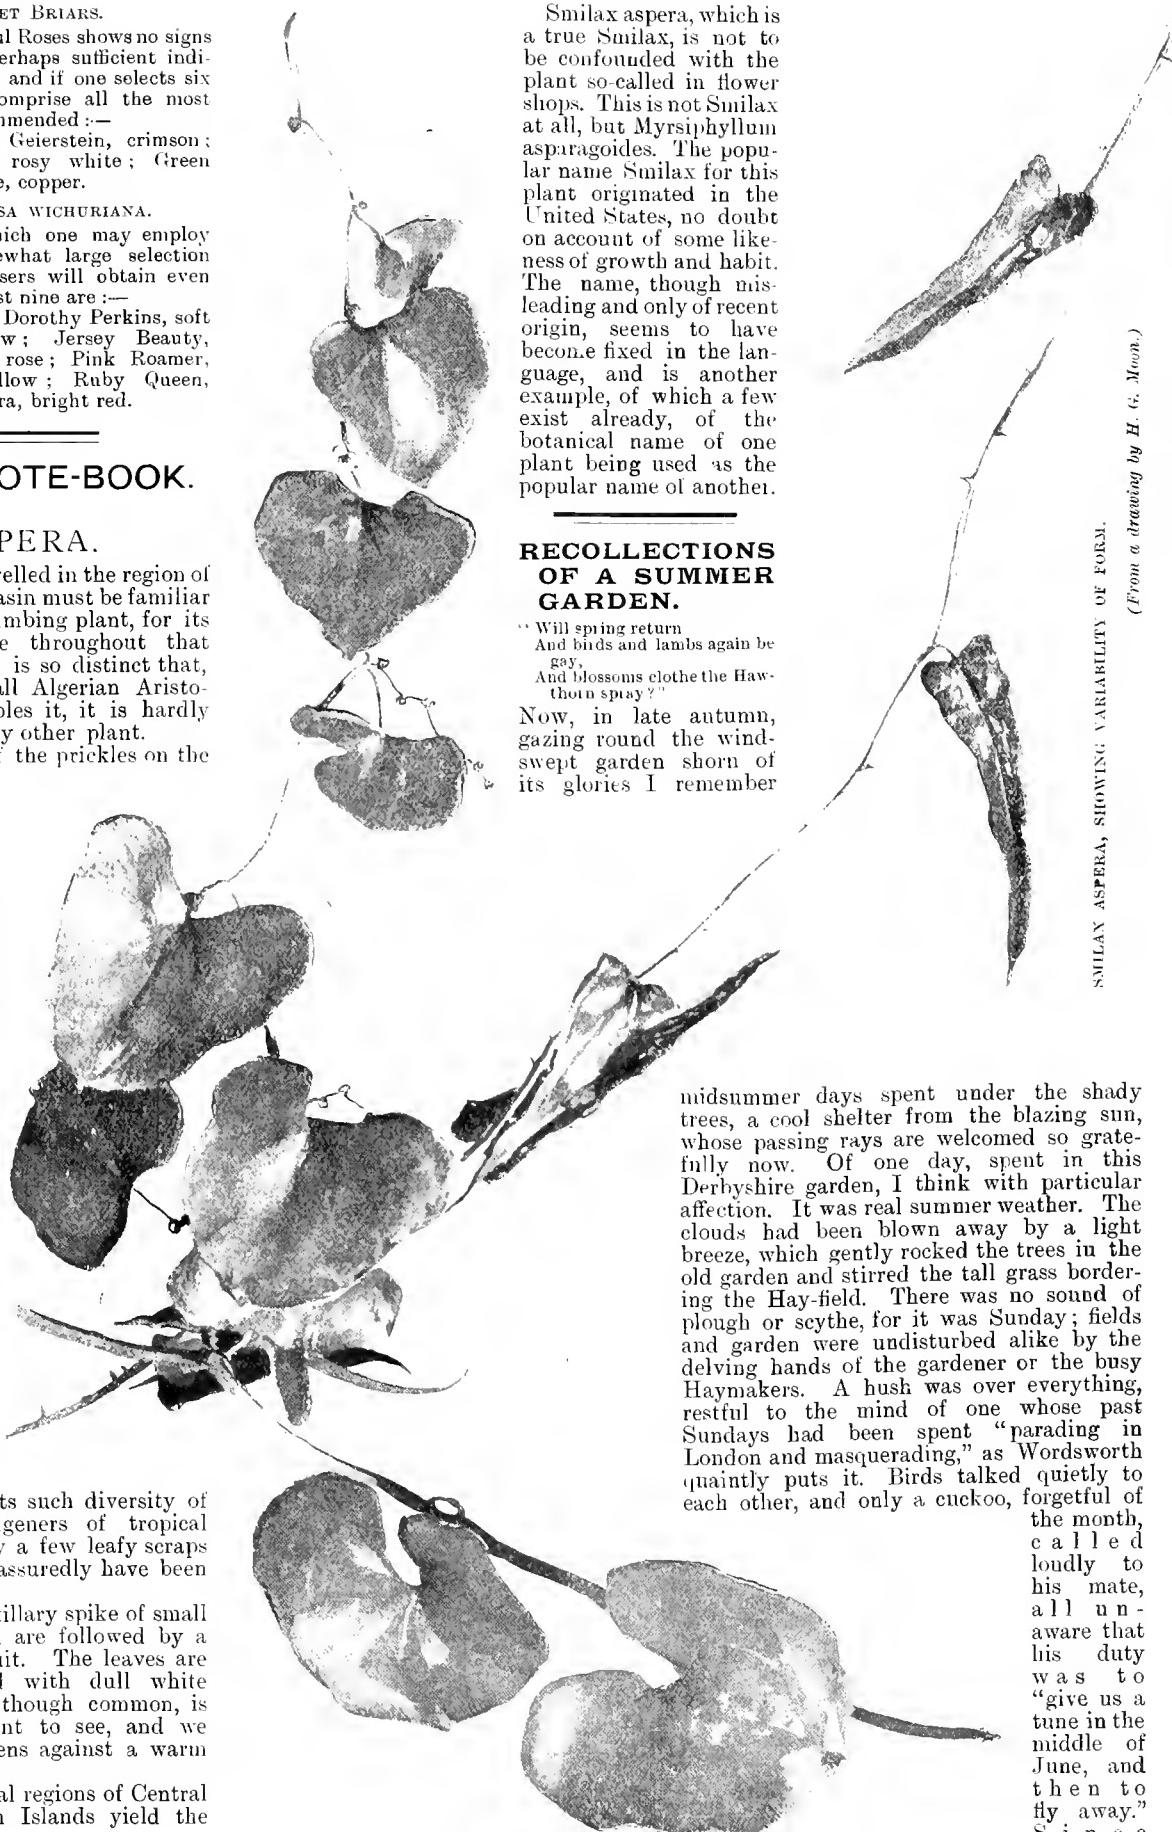

Now, in late autumn,  
gazing round the wind-swept garden shorn of  
its glories I remember

(From a drawing by H. G. Munro.)

SMILAX ASPERA, SHOWING VARIABILITY OF FORM.

midsummer days spent under the shady trees, a cool shelter from the blazing sun, whose passing rays are welcomed so gratefully now. Of one day, spent in this Derbyshire garden, I think with particular affection. It was real summer weather. The clouds had been blown away by a light breeze, which gently rocked the trees in the old garden and stirred the tall grass bordering the Hay-field. There was no sound of plough or scythe, for it was Sunday; fields and garden were undisturbed alike by the delving hands of the gardener or the busy Haymakers. A hush was over everything, restful to the mind of one whose past Sundays had been spent "parading in London and masquerading," as Wordsworth quaintly puts it. Birds talked quietly to each other, and only a cuckoo, forgetful of

the month, called loudly to his mate, all unaware that his duty was to "give us a tune in the middle of June, and then to fly away." Since

morning service in the tiny grey church beyond the village street the day was spent in the garden in profound content, grateful for the heat which made up for the sunless days of the past week. The flower-beds on the lawn were a blaze of Roses, deep pink La France, crimson Duke of Edinburgh, and orange Allen Richardson. An impudent Field Poppy had planted himself in the Rose border. He had apparently walked out of his lawful corner by the dining-room window, not liking his company there and being a pushing fellow. In this most charming of gardens an ancient red brick wall divides vegetables from flowers. In the widening spaces made by falling mortar (assisted by sharp beaks) were the remains of tiny nests built last spring. The border beneath was full of brilliant colour. More Roses climbed the wall, peeping over to look pityingly at Beans and Potatoes that flourished on the other side, and Ivy clung to it. Blue Larkspur and tall Foxgloves formed the border, a background to white Pinks and clumps of Pansies, purple, yellow, and white. The rain of the last few days had hurried on the Lilies, for the buds already showed white through their light green sheaths, and I could almost smell the Lilies in advance. Further on were masses of dark red Snapdragon, and whole chimes of Canterbury Bells, blue and white. At the corner, where the path turned off through a trellised archway into the kitchen garden, stood a huge Lavender bush, which was only waiting a while to make the air sweet and drown all other scents.

Derbyshire is a county of beautiful trees, and this particular spot is no exception to the rule. This garden is all on different levels, and on the sloping lawn stands an enormous Copper Beech, towering over the Cedar next it. The Beech was (on the day of which I write) a mass of bronize leaves and shapely branches. The drive is bordered by rows of big Planes and shady Limes, while Chestnuts will soon shoot up from slender saplings and eclipse their older companions. Seeing this wealth of leafy branches, it is easy to believe the old legends of the dryads who live in trees and who die when the trees are cut down or injured. I can imagine dainty fairies clad in green descending at night from these trees to dance on the lawn. Perhaps the soft fall of leaves heard through the stillness of a summer's night may be caused by fairy feet treading the branches. Beyond the garden proper are Hay-fields. The Hay had just been carried that midsummer day, and was already piled in sweet smelling stacks for winter use.

The gardener had been complaining sadly of the rabbits, who had come from the fields in the night and eaten the plants in some beds that he was depending on to render the garden cheerful, when Roses and Lilies and other summer joys should have departed. He prepared a wiry welcome for them, however, in the shape of stiff fencing to surround the cherished flower-beds. At the bottom of the field nearest the house are two ponds, the home of duck and waterhen. In the thick reeds by the bank lived a thriving family of coots, tiny black objects with scarlet heads, who paddled behind the parent bird like little steamers on a gigantic lake. By now they have lost their smart red caps and put on white ones, which are not nearly so pretty. At the other side of the pond a dun-coloured foal kicked up his heels light-heartedly as he galloped round the field, followed by his sedate mamma, who ambled along heavily, flicking the flies from her sleek back with her tail. The foal look absurdly unfinished, as if he had

been hastily sewn into his rough skin. His tail seemed not to belong to him at all, nor did his legs fit. But as I leant over the garden wall, watching his gambols, the shadows began to lengthen over the lawn and a faint chill crept into the air, the blue sky turned to purple shot with gold, and I realised with regret that the glorious summer's day was done.

"The sky is glad that stars above  
Do give a brighter splendour,  
The stars unfold their flaming gold  
To make the ground more tender."

DOROTHY HAMILTON DEAN.

## CORRESPONDENCE.

(*The Editor is not responsible for the opinions expressed by correspondents.*)

## PLANTS NOW IN FLOWER.

[*To the Editor of "THE GARDEN."*]

SIR,—I enclose a list of plants flowering in my garden on the 20th ult., which may prove of interest to some of your readers. The plants in most cases were in full flower, Sweet Peas and Roses being cut daily in large quantities. The garden lies on the east coast of Scotland, six miles from the sea, and about 400 feet above sea level.

*Linum rubrum, Papaver bracteatum, P. umbrosum, P. pilosum, Humea elegans, Stocks, Lilium auratum, Echinops Ritro, Helianthus in variety, Roses, great variety and quantity, Spiraea A. Waterer, Cyclamen europaeum, hardy Cyclamen, Alonsoa in variety, Scabious annual, S. caucasica, Gaillardias, Dianthus superbus, Pinks, Phygelius capensis, Delphinium ann., Nemesia strumosa, Marigolds, Coreopsis grandiflora, C. auriculata, Rudbeckia Newmanni, R. tomentosa, and R. laciniata, Eryngium amethystinum, Salpiglossis, Morina longifolia, Gypsophila paniculata, G. prostrata, Matricaria inodora fl. pl., M. Golden Ball, Centaurea Cyanus, Potentilla, Lobelia fulgens, L. siphiliticus, L. cardinalis, Ceanothus Glore de Versailles, &c., Sunflowers, Alstroemeria, Colchicum, Schizanthus, Mignonette, Lobelia (blue), Chrysanthemum burridgeanum, Agathea celestis, Lysimachia clethroides, Tagetes, Alyssum (pale lemon), Genista tinctoria, Fuchsias, Hydrangea paniculata, Nasturtium, Erigeron mucronatus, Malva moschata, Lavatera trimestris, Michaelmas Daisies in var., Francoa ramosa, Cassia corymbosa, early-flowering Chrysanthemums, Doronicum, Senecio pulcher, Auriculas, Helenium autumnale, Enothera lamarckiana, Pyrethrum uliginosum, Chrysanthemum maximum, Enothera Fraseri, Agrostemma coronaria, Anemone japonica, Dicentra eximia, Statice in var., Aubrieta in var., Dahlia Zimpani, Sedum in var., Pyrethrum The Pearl, Nepeta Mussini, Geum Heldreichii, Monarda didyma, Arabis albida fl. pl., Veronica salicifolia, V. subsessilis, V. spicata, V. rupestris, Hemerocallis, Nemophila insignis, Eschscholtzia, Schizostylis coccinea, Violets, Nicotiana affinis, N. grandiflora purpurea, N. sylvestris, Papaver orientale, Clematis, Ageratum, Celsia cretica, Clarkia, Dahlia, Gladiolus, Antirrhinum, Godetia, Montbretia, Phacelia, Larkspur, Carnations in var., Tritomas, Hollyhocks, Sweet Peas, Calceolaria amplexicaulis, Phlox Drummondii, Salvia coccinea, S. Bluebeard, S. patens, Linaria in var., Helianthemum in var., Verbascum cupreum, V. olympicum, Sidalcea Listeri, Verbenas, Gazaoia splendens, Escallonia, Geranium in var., Loasa aurantiaca, Hunnemannia fumariifolia, Harrisson's Musk, Campanula turbinata, C. pyramidalis, C. persicifolia, C. glomerata, Primula capitata, Polyanthus, Primroses in var., and Phloxes.*

Preston Hall, Dalkeith, N.B.

C. M. C.

## CARNATIONS AND PICOTEES.

[*To the Editor of "THE GARDEN."*]

SIR,—I have read Mr. Weguelin's letter on the above subject in your issue of October 25 with

much interest. It is doubtless true that good Carnations have been raised in various places, and it is indisputably the fact that a large proportion of the choicest varieties at present in cultivation have emanated from Hayes. This does not, however, prove that every seedling sent out from Hayes is a gem of the first water, neither does it prove that seedlings from other growers are worthless. Yet so unaccustomed has the public become to expect good things, except from Mr. Martin Smith, that they are slow and perhaps unwilling to appreciate the undoubted merits of varieties from other raisers. So keen, however, is the competition nowadays that this state of affairs must inevitably and at no distant date right itself.

I notice Mr. Weguelin, like another West Country grower, is leading a crusade against "dressing." Doubtless the ideal flower requires no dressing, but where is such a flower to be found? Who is the happy raiser? As I understand it, the primary object of a Carnation show is as a trial of skill between more or less experienced growers. I take it that a show is held not so much as a test of the artistic taste of the exhibitors, but as a test of their ability in growing Carnations to the highest possible state of perfection. If "dressing" exaggerates the good qualities of a flower, are not the defects of an inferior bloom likewise brought into prominence, thus emphasising the difference between good and bad flowers and rendering easier the onerous duties of the judges?

When grown to show proportions our best Carnations are perhaps scarcely suitable for vase or dinner-table decorations, but the exact opposite is the case in another section to which Mr. Weguelin alludes—I mean the American tree varieties. Here we have a class eminently suited to the decorator's art. They may not have the qualities desired by the exhibitor—the broad, flat, smooth petal of velvety texture is absent, the centres are full and high, a mass of light feathery petals with serrated edges. Yet they have a glorious beauty of their own which must be seen to be appreciated. Their large deep flowers give the appearance of great balls of glowing colour; the calyx never splits; the stem, frequently 2 feet or more in length, is stiff and wiry, and supports the great bloom by which it is surmounted unaided. Most of these Carnations are fragrant and in constant bloom from October to May. Large as they are they never look coarse or heavy, and can be massed in quantity with the best effect.

Let us keep everything in its right place—the show varieties properly dressed in paper collars and the decorative varieties in vases or espaguetis with suitable foliage. Why cannot a show be held in winter for English and American perennials? Surely it would be a pleasant sight in the dull days of November or December to see the Drill Hall full of these beautiful flowers exhibited "as grown," and I for one would willingly co-operate in the establishment of such an exhibition if one could be inaugurated for next year.

HAYWARD MATHIAS.

Thames Ditton, Surrey.

## SHRUBS FOR A JAPANESE GARDEN.

[*To the Editor of "THE GARDEN."*]

SIR,—Would you please give a list of Japanese evergreen shrubs suitable for a Japanese garden? I am making also a collection of spring-flowering Japanese bulbs.

THEODORE WALKER, F.R.G.S.

[We hope the following list will be found helpful:—

*Evergreen Japanese Shrubs.—Aralia Sieboldii, A. S. variegata, Buxus japonica, Camellia japonica, C. Sasanqua, Cleiera japonica, C. j. variegata, Daphniphyllum macropodum, Elaeagnus macrophylla, E. pungens, E. p. aureo-maculata, E. p. a. picta, E. p. variegata, Euonymus japonicus, E. j. aureo-marginatus, E. j. argenteo-variegatus, E. latifolius albo-variegatus, E. radicans variegatus, E. r. Silver Gem, Ilex crenata (syn. Fortunei), I. e. variegata, I. latifolia, Illicium religiosum, Ligustrum japonicum, Quercus cuspidata, Q. c. variegata, Skimmia japonica, S. j. Foremanii, Viburnum odoratissimum, Clethra canescens,*

*Andromeda japonica*, *Pernettya mucronata* in variety, *Raphiolepis japonica*, *Azalea balsamine-flora* (syn. *Rollisonii*), *Daphne odora*, *Magnolia grandiflora*, *Osmanthus ilicifolius*, *O. i. purpureus*, *O. i. variegatus*, *Rhododendron M-tternichii*, *Benthamia japonica*, and *Berberis japonica*.

*Japanese Conifers*.—*Cryptomeria japonica*, *Cunninghamia sinensis*, *Juniperus rigida*, *Pinus densiflora*, *P. koraiensis*, *P. parviflora*, *P. Thunbergii* (*massoniana*), *Podocarpus macrophylla*, *P. m. variegata*, *Sciadopitys verticillata*, *Taxus cuspidata aurea*, *Thuja obtusa* in variety (*Retinospora*), *T. pisifera* in variety, *Thujopsis dolabrata*, *Juniperus japonica*, *J. j. aurea*, *Abies Veitchii*, *A. alcockiana*, *A. polita*, *A. brachyphylloides*, *A. firma*, *A. Sieboldii*, *A. Tsuga*, *Cephalotaxus drupacea*, and *Juniperus chinensis*.

*Spring-flowering Bulbs*.—*Adonis amurensis*, *Fritillaria japonica*, *F. kamschatkensis*, *Narcissus Iris chinensis*, *I. Kampferi*, *Lilium thunbergianum*, *Dicentra spectabilis*, *Saxifraga peltata*, and *Narcissus Tazetta*.

## THE FRUIT GARDEN.

### A NEW BULLACE.

**O**N November 4 Messrs. James Veitch and Sons, Limited, Chelsea, obtained an award of merit from the Royal Horticultural Society for a new fruit—Langley Bullace.

This was obtained from a cross between Farleigh Prolific Damson and Orleans Plum. The fruits of the new Bullace are the size of the latter, and produced with all the abundance that characterises the Damson. They are ripe early in November and will hang late. After the Damsons and Plums are over, therefore, this Bullace should prove of great value.

### HARDY FRUITS IN SEASON.

#### PEAR WINTER NELIS.

MR. CROOK sends from Forde Abbey Gardens, Chard, a few fruits of this delicious Pear to remind us of its juiciness and refreshing flavour at this time. No winter Pear is more welcome than this; it is not large, but of pretty shape, with quite a rich brown skin, and is a dainty dish until Christmas. No amateur should be without a few trees of Winter Nelis, the best of all winter Pears.

#### APPLES.

*Cox's Orange Pippin*.—In the latter part of November and early in December several of the best dessert Apples are ripe, and the popular Cox's Orange Pippin heads the list. A few words will suffice to note its value. It has so far no equal with regard to quality, and it should find more room in gardens on this account. My experience is that we trust too much to variety and lose sight of flavour.

*Ribston Pippin*.—This is also in season, and is almost on a level as regards flavour with Cox's Orange. On the other hand, Ribston fails where Cox's Orange thrives, the last-named doing well in a young state and as a bush or standard. I advise Ribston to be grown as a bush. Grown thus it does not canker so badly, a fault the Ribston is much subject to.

*Allington Pippin*.—A new variety of great excellence, almost rivalling both the above fruits. It is handsome when well grown, and a certain cropper on dwarf trees. In flavour it is brisker than Cox's Orange, and I find it at its best at this season.

*Charles Ross*.—This has been introduced too recently to note its cropping qualities but I

am informed that in this respect it is first-rate. My note now refers to its value at this season—November and early December—as a first-rate dessert variety. It is larger than the parent, Cox's Orange, and will certainly have a great future if it crops freely. Intending planters should include it in their list.

G. WYTHES.  
*Syon, Middlesex.*

### BACK TO THE LAND.

PUBLIC attention of late years has certainly been more directed towards the importance of the minor industries of the land, both in connexion with the garden and the farm, as bearing on the national food supply, and the well-being and happiness of our rural population, than was formerly the case. As one of these minor industries, the Pear, I think, may lay claim to be one of the most important. There has been an impression and a prejudice amongst the English people that Pears of the highest quality cannot be grown in England, but must be sought for chiefly in France and the Channel Islands. It is a fact, I

admit, that the Pears from these places exhibited in our markets and fruiteers' windows are finer in appearance, and sometimes better in quality, than is our English-grown fruit; and it may be reasonably asked if this is so, why is it so? The majority would, I have no doubt, answer this question off-hand by saying that the climate of these countries being warmer and more suitable for the growth of the Pear is entirely accountable. Having visited the Pear gardens both of France and the Channel Islands, where I had an opportunity of witnessing the systems adopted of cultivating the Pear by these growers; this by them is reduced to a fine art, to which they devote as much care, attention, and patience as we do to our choicest fruits under glass in England. Not only in the growing of the fruit is this great care manifested, but the same anxious care is given to the harvesting, packing, and the attractive way in which the fruit is placed before the public, resulting in splendid returns in the way of highly remunerative prices. How does the case stand as regards the thought, care, and attention given to the cultivation of the Pear in England in comparison? I grieve to say there is no comparison whatever. In the former countries, as I said before, the subject is of vital importance to the tillers of the soil, and no care or thought is considered too great to give to its consideration, as well as to the selection of the varieties which suit the markets best; and these are reduced to the fewest number in order to simplify and cheapen the work of production.

In England the growth of the Pear has never been taken up in this spirit; indeed, as a commercial article, excepting in Hereford, Worcester, Kent, and a few other counties, where orchards of it exist for the purpose of furnishing fruit for the

LANGLEY BULLACE.  
(A new fruit, given an award of merit by the Royal Horticultural Society recently.)

manufacture of Perry, the Pear has been entirely neglected. Those growers who have taken the subject in hand for commercial purposes on a large scale in this country may be counted on the fingers of one's hands; and even in private gardens not many gardeners have given that time and thought to the subject which is absolutely necessary if the best results are to be obtained. Judging from the few Pear orchards that are still existing in the neighbourhood of London and other districts favourable to the growth of the Pear, our forefathers thought a great deal more of this fruit than we of the present generation do. These trees, many of them are of huge size and great age, and all growing on the Pear stock, and which have received absolutely no attention to speak of in manuring, pruning, or thinning the fruit; and it is from these mostly that Pears are supplied for our poorer markets, and even these half-grown, bruised, and fallen fruits (in gathering they are usually shaken off the trees) command a ready sale at fair and remunerative prices. From the foregoing it is clear that if English Pear growers are to compete with success against French and Channel Island growers, greater care and skill must be applied to the industry. The point as to the relative excellence of English and Jersey Pears was forcibly brought out at the great hardy fruit show held by the Royal Horticultural Society at the Crystal Palace last autumn (1901), where an excellent collection of hardy fruit, chiefly Pears, was exhibited by a Jersey firm, Messrs. Bulerell and Co. Excepting some few odd dishes, where the specimens were larger, the best English samples on view at the exhibition were equal in every respect to the Jersey ones. A revolution in the improved method of the growth of the Pear has been quietly taking place

for years, ever since the Quince has been substituted for the Pear stock for working the trees on. It used to be an old saying (and true enough in those days) that "the man who planted Pears planted for his heirs." This proverb has at present no longer any force, as the Pear worked on this dwarfing stock can be made to yield fruit in half the time it used to take when grown on the Pear stock. The importance of this change, in so materially shortening the time in which the young Pear tree can be made to bear fruit, has already wrought a great change in favour of Pear planting, as well as in the much and generally improved quality of the fruit now seen, as compared with that occasionally exhibited years ago. Another point of importance as bearing on the popularity and the largely extended planting of the Pear, is the fact, conclusively brought out since more attention has been given to the culture of this fruit, that the old belief that a warm wall was an absolute necessity for its successful culture, is a phantom of the past; and the fact proved that a great number of our choicest and best varieties which at one time it was thought could only be grown to perfection against a wall, can now be grown to greater perfection certainly as regards flavour, in the open quarter; and this fact, when better known will, I trust, be the means of multiplying Pear growers in this country a hundred-fold, especially in the warmer counties, where the conditions are favourable. I cannot conceive of any work calculated to give those who engage in it greater pleasure or profit, whether it be the humble cottager, the amateur, or the commercial grower, than the study and practice of the growth and fruiting of the Pear, or one attended with greater satisfaction at the end in the enjoyment of the ripe fruit, or its equivalent in cash returns from the market. A. P. H.

## GARDENING OF THE WEEK.

### THE FRUIT GARDEN.

#### PRUNING PEAR TREES.

**P**RUNING of fruit trees should be persevered with as time and weather permit. Matured horizontal and fan-trained Pear trees upon walls are liable to become encumbered with overgrown strong spurs, which, by producing a dense growth of gross shoots and leaves, exclude the sun and air to a great extent, and either prevent the formation of fruit buds or cause those that do form to be weak and incapable of yielding good fruit. This state of things should be rectified by root lifting, and pruning (which has been recently treated of), combined with the skilful use of the knife, by cutting out the unfruitful strong portions of the spurs, which are usually prominently placed, and also the unduly weak useless parts. The eye of a skilled pruner readily discerns these, but it is advisable in bad cases to let the treatment extend over two or three years rather than severely thin in one season. The young ends of extending branches upon young trees should be shortened in a degree that will ensure the development of suitable branches adequately to furnish the trees, and the young wood which was shortened back at the time of the summer pruning should be now pruned to two or three buds.

#### CORDON TREES.

Any necessary training and pruning required at the present time by this form of tree is most simple to understand, and whether the trees have two stems or only a single one it needs but little explanation. If the varieties most suitable (and some are much more so than others) for this mode of culture are worked upon the Quince stock, and planted in favourable soils and positions, very little trouble further than ordinary pruning will be required, but when worked upon the free stock, especially if planted upon strong soils, some varieties in particular make gross wood and useless spurs, conditions which must be counteracted by root lifting and spur manipulation. Unsatisfactory

stems can be readily replaced by training shoots in their places which emanate from the base of the trees. Trees that have exhausted their soil and are languishing in consequence should be assisted by the surface soil being removed down to the roots and replaced with good loam, freely incorporating wood ashes and bone-meal. We use diluted liquid manure from stables for this purpose, and find it an invaluable invigorator to trees possessed of satisfactory roots.

#### PYRAMIDS AND BUSHES.

The winter pruning of full-sized trees consists in shortening back to two or three basal buds the spurs left long at the summer pruning, and this will dispense with any sappy secondary growths that may have formed, overgrown spurs being at the same time treated as advised for wall trees. Some varieties that bear their fruit chiefly upon the points of short shoots will, of course, require the most desirable of these to be retained in order to secure a crop of fruit. T. COOMBE.

*The Hendre Gardens, Monmouth.*

#### ORCHIDS.

##### HYBRID CATTLEYAS AND LÆLIO-CATTLEYAS.

WHERE a large number of these are grown, it is convenient if a house can be devoted to them during winter, and a few degrees more heat maintained, say, 65° by night and 70° by day, for the following reason. With the majority of Cattleya and Lælia species generally it is necessary to modify the temperature and application of water to the roots when the season's growth has finished, in order if possible to prevent the plants again starting into growth, for if a second growth is made, even if encouraged, it is seldom satisfactory. The hybrids, on the other hand, do not need a long season of rest, as is necessary for the species, for when one growth has fully developed they seldom remain more than a few weeks before they again start into growth, thus causing many plants to grow during the late autumn and winter months. If a few degrees more heat therefore are given during that period than necessary for the Cattleyas and Lælias in a resting stage the second bulb will be as fully developed as the preceding one, though owing to lack of sunlight it is perhaps not so well ripened. Where a few hybrids only are grown they should be placed at the warmest end of the Cattleya house during late autumn and winter if the temperature of both ends is equal. A difference of a few degrees is easily made by not opening the ventilators so wide at one end.

*Lælio-Cattleya Ingramii* (*Lælia pumila dayana* × *Cattleya dowiana aurea*).—This is a handsome dwarf hybrid, the sepals and broad petals are rosy mauve, and the lip deep maroon-crimson; it flowers in the autumn and winter, and seldom fails to bloom when the growth has reached its normal stage. *Cattleya dowiana aurea* enjoys a few degrees more heat than many of the Cattleyas, while *Lælia pumila dayana* needs less, thus causing *L.-C. Ingramii* to be a suitable occupant for the Cattleya house proper. It may be grown in pots, pans, or baskets in a light position; the latter is essential, for it is with these brilliant coloured hybrids, as with the species, if shaded too much or grown in houses where a maximum amount of light is not obtained they deteriorate and the true character of their flowers is not revealed. *L.-C. Broomfieldense*, *L.-C. Clive*, and *L.-C. Normanii* are offspring of the same parents as *L.-C. Ingramii*, which they much resemble both in habit and character of flower.

*Lælio-Cattleya Aphrodite* (*Cattleya Mendelii* × *Lælia purpurata*).—This handsome hybrid of vigorous growth is best grown in pots; it is now in bloom, and the presence of so beautiful a flower is much appreciated at this season.

*Cattleya Mantinii* (*Cattleya bowringiana* × *Cattleya dowiana aurea*).—This in growth and manner of flowering much resembles the former parent, though the flowers are much larger and of better quality. The sepals and petals are rose-purple, lip dark purple with golden veinings. It has just passed out of bloom, and like other hybrids should be kept somewhat drier at the roots during the short time it is inactive. Pot culture is most suitable.

*Lælio-Cattleya Bryan* (*Cattleya gaskelliana* × *Lælia crispa*).—This ranks among the most beautiful of the autumn and winter flowering hybrids. It is very striking in appearance, its crimson-purple frilled lip being its best feature. The sepals and petals are white, faintly suffused with rose. No collection should be without this desirable hybrid.

*Lælio-Cattleya Leucasta* (*Cattleya bicolor* × *Lælia harpophylla*).—This bright little hybrid is now in flower, and though not showy is very interesting and distinct. In growth it resembles *Lælia harpophylla*; the flowers are about 3 inches across. The sepals and petals are pale orange-yellow, lip light purple, yellowish white towards the apex. This is best grown in the coolest part of the Cattleya house. F. W. THURGOOD.

*Rosslyn Gardens, Stamford Hill, London, N.*

## THE KITCHEN GARDEN.

#### FORCING.

IN large gardens much attention must now be paid to forcing to maintain a fresh and regular supply, and where means are at hand little difficulty will be found in doing so. On the other hand, where such facilities do not exist and the demand is great, it will entail much labour and forethought for the next two months to meet the requirements.

#### RHUBARB.

Owing to the scarcity of the Apple crop in many places, Rhubarb will no doubt be in great demand, consequently large quantities should be got up and heeled in where it can be safely protected from frost and introduced to heat as required. Rhubarb always starts away more freely when lifted with plenty of earth and placed in a dry heat. Moisten the crowns frequently.

#### SEAKALE.

Place good batches of crowns in the Mushroom house about every ten days in the warmest and darkest position. Trim off and tie all the rootlets in small bundles, and store away in a cool place ready for starting into growth in the spring for next season's supply.

#### ASPARAGUS.

is doing remarkably well this year. Mild hot-beds should be kept made up and fresh roots introduced every fortnight to avoid a break.

#### FRENCH BEANS.

Now is about the most difficult time of the whole year to produce these, nevertheless they are generally much appreciated, and well worth the trouble expended on them. Give them a position as near the glass as possible in a strong moist heat. Weak doses of warm manure water should be given to those in bearing every alternate watering, and thoroughly syringe the foliage on bright mornings. Make sowings every fortnight in 7-inch pots. Canadian Wonder is a capital kind for this time of the year; it takes a little longer to mature, but being a robust grower it is better able to hold its own during the short dull days of winter.

#### CARROTS.

No time should be lost in preparing a place for early Carrots. No better place can be given to them than a heated pit, in which should be placed some sweet fermenting material, Oak or Beech leaves being best for the purpose. Use a mixture of light loam, leaf-soil, old Mushroom bed manure, and road grit in equal proportions, which should be made up to within about 10 inches of the glass. Carter's Early Long Forcing is a capital variety for forcing now, as it makes little top, quickly matures, and is of excellent quality.

#### SALADING.

Place plenty of Chicory and Dandelion in heat in quite a dark position, both of which force quite easily and are generally much liked. Blanch Endive as required by tying it up fairly tight when dry.

#### LETTUCE.

Generally none too plentiful during February, but if small sowings of Carter's Harbinger are made now in a mild heat, and pricked out thickly in boxes when ready and kept gently growing, they

may be cut like Mustard and Cress, and make excellent material for the salad bowl.

## TARRAGON

if not already done, should be lifted, boxed, and placed in a gentle warmth.

Thinly in boxes sow Onions for drawing in a young state, and sow small salading weekly in boxes under glass.

E. BECKETT.

*Aldenham House Gardens, Elstree, Herts.*

## INDOOR GARDEN.

## ACALYPHAS.

THESE very handsome subjects make excellent house plants. Old and ungainly plants that have useful cuttings on them should have them removed and placed singly in small pots in a sandy mixture of soil and put in the propagating case to root, there will be then no further need to retain the older plants. Root a batch of *Panicum variegatum* for edging the stage. Place five or six cuttings in a 3-inch pot, and keep rather moist in a propagating frame. *Ficus radicans variegata* should be similarly treated. Unfortunately, this plant does not grow so freely as the former, and should be afforded a good bottom heat, and less moisture at the root and overhead. *Ficus elastica* is readily struck from half-ripened growth and buds, but the wood must not be too old. Cuttings of *Abutilons* may also be inserted, selecting well-developed shoots, and place singly in small pots. *Panax Victoriae* and many similar plants may be rooted in batches. Every effort should be made to push all possible propagating forward before the New Year. Such work done now will economise labour at a time when usually all available assistance and space are wanted. Before removing the cuttings let the plants be thoroughly cleansed, using some reliable insecticide for the purpose. We have had the best results from December-rooted plants.

## CROTONS.

Cuttings put in as previously advised that have rooted satisfactorily should be transferred from the small pots into 4½-inch ones. A suitable mixture is one consisting of two parts fibrous loam, one part leaf-mould, and the remaining part made up of wood ashes and sharp silver sand, with a dusting of dissolved bones added; liberal drainage and firm potting are essentials. Keep the plants clean by frequent use of the syringe, and full

exposure should be given to every glare of sun. For established plants when the pots are well filled with healthy roots, liberal feeding is of great advantage. They also delight in plenty of heat and moisture.

## IXORAS

that are rooted in small pots should be placed into 5-inch ones. Make use of a compost of fibrous peat, to which a little fibrous loam should be added, and plenty of sharp sand to keep the compost porous; give free drainage and press the soil firmly round the roots. These subjects delight in a strong heat and moisture during the growing season. Established plants may have less water and a cooler temperature during their resting season. Ixoras are liable to the attacks of red spider, thrip, scale, and mealy bug. To keep these pests in check a safe insecticide should be used, thoroughly washing the foliage and stems.

Wexham Park, Slough.

JOHN FLEMING.

## ORCHIDS.

## THE ORCHIDACEÆ.

DURING recent years much attention has been paid to the cultivation of Orchids, and there are now few gardens in England that do not possess some at least. Orchids are most abundant in the hot damp regions of the tropics, where they thrive in the greatest profusion, not always, as in the colder climes, deriving their nourishment from the earth, but being supported by the moisture-laden air.

Few Orchids are of any medicinal value, and though the flowers of some species are highly fragrant, no perfumes are extracted from them; the dried fruit of *Vanilla planifolia* forms the Vanilla of commerce, largely used for flavouring purposes.

Although separated from the tropics by hundreds of miles of land and water, yet we too in England have nearly fifty indigenous species of Orchids. Many of them are local and rare, but at least half a dozen species are common in most parts of the British Isles. They grow chiefly on chalky soil, and are most common in Hampshire and Sussex.

The formation of the lower lip of the corolla is

in some of our native Orchises very singular, often resembling certain insects in form, size, and even colour—such are the Bee, Fly, and Spider Orchis. Sometimes the same organ presents a striking resemblance to some of the more important inhabitants of the animal kingdom—e.g., the Man, Monkey, and Lizard Orchis. The same mimicking extends to exotic species. "So various are they in form," says Dr. Lindley, "that there is scarcely a common reptile or insect to which some of them have not been likened."

FRANK GAMMON.

*Hamstead Park Gardens, Newbury, Berks.*

## CATTLEYA LABIATA VAR. AMESIANA.

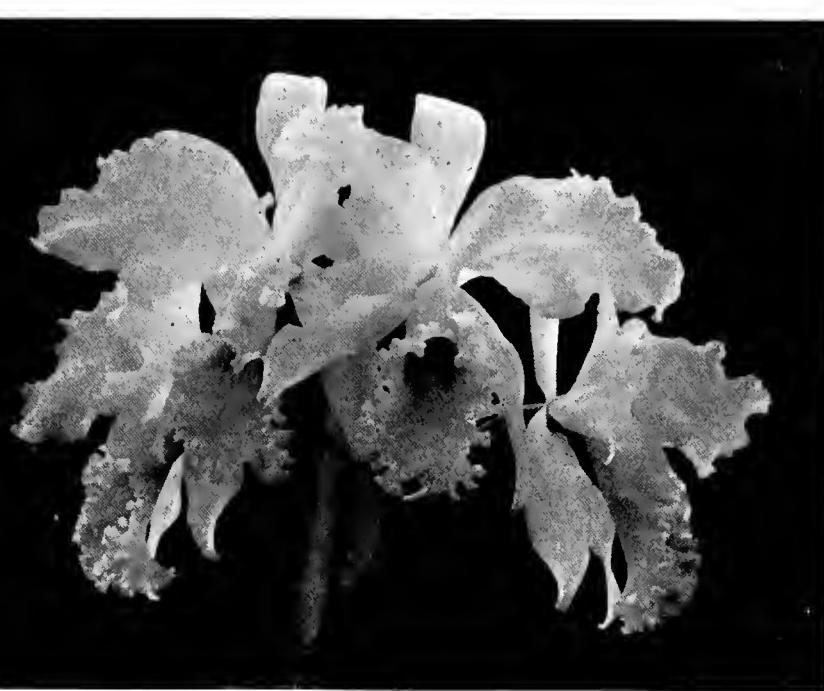

UNDoubtedly this is one of the most beautiful white forms of *Cattleya labiata* yet found. Messrs. Hugh Low and Co., Bush Hill Park Nurseries, Enfield, Middlesex, introduced this variety, and named it in compliment to Mr. Oakes Ames, of Boston, U.S.A., because, we believe, of its great resemblance in colour to *C. trianae amesiana*, which Messrs. Low also introduced. *C. labiata amesiana* was given an award of merit by the Royal Horticultural Society when shown by Messrs. H. Low and Co. and by J. Bradshaw, Esq., The Grange, Southgate, N., on November 4. It has pure white sepals and petals, with a true lilac labellum. The plant shown by Messrs. H. Low has passed into the possession of Richard G. Thwaites, Esq., 23, Christchurch Road, Streatham, who makes a speciality of albino forms. Another plant of this variety was shown by Messrs. Low and Co., before the Orchid Society, at Manchester, on November 6, when a first-class certificate was unanimously granted.

## BOOKS.

## Formal Gardens in England and Scotland.\*

The third part, just published, completes this important work on formal gardens, which we notice is dedicated to Her Majesty the Queen. We reviewed the first and second parts at some length, and readers will therefore already know something of the object and scope of the splendidly printed pages in front of us. That the reproductions of gardens are superb goes without saying, as the work of Mr. Latham is recognised as the finest of our time, and in the three parts there are fifty-two of these reproductions from photographs with seventy-three from the author's measured drawings. We may briefly state that the illustrations consist of entire plans, and photographic and perspective views of existing gardens, together with sketches, measured drawings, and photographs of gates, terraces, balustrades, steps, garden rooms and summer houses, bridges, columbaries, sundials, figures and vases in lead and stone, fountains and ponds, topiary work, &c. Part III. contains photographs of some good and instructive views at Montacute, Wilton, Hatfield, Rockingham and Brington Castles (Rose gardens), Saffron Walden, Arley Hall, Belton, Levens, Brickwall, Melbourne, Westbury, Groomebridge Place, Holland House, Chiswick House, Hampton Court (Herefordshire), Little Compton, Dawley, Fairford, lead figures at Nun Moneton, Yorkshire, lead vases at Wilton House and Chiswick House, lead garden cisterns at Charlton House and Victoria and Albert Museum, also at Enfield Old Park, stone vases from Stoneleigh Abbey, Drummond Castle, West Park and Melbourne Hall, fountains at Wilton House and the Victoria and Albert Museum, stone balustrades at Drayton House, Brympton Manor, Borwick Hall, and Cranborne Manor, wall gateways at Penshurst, Earlshall, Cold Ashton, and Oundle, and mazes at Somerleyton Hall, Arley Hall, Belton House, and from Hill's "Arte of Gardening," and the Harleian

\* "Formal Gardens in England and Scotland." By H. Inigo Triggs, A.R.I.B.A. Published by B. T. Batsford, 94, High Holborn, London.

CATTLEYA LABIATA VAR. AMESIANA. (Given an award of merit, Royal Horticultural Society, November 4.)

MSS., British Museum, besides a series of carefully drawn plans which are of extreme interest to all students of old English gardens of formal design. Nothing reveals the character of a book more than a carefully selected extract, and we therefore take the following description of Levens Hall, Westmorland, from its pages.

#### LEVENS HALL.

"The old Dutch garden at Levens Hall is probably the most perfect example remaining in England of a garden designed under the Dutch influence prevalent soon after the accession of William and Mary, although, curiously enough, the designer happened to be a Frenchman, but there is certainly nothing French about the aspect of Levens, which was evidently copied almost directly from a Dutch model, and in all their main features the gardens have been handed down to the present day exactly as they were originally designed.

"Levens Hall dates back to very remote days, and was probably built as a border 'pele' tower, of which there are many examples still to be met with in these parts. In 1489 the property was acquired by one Alan Bellingham, and it remained in his family until 1689, when it was sold to Colonel James Grahame, Keeper of the Privy Purse to James II. and one of his most trusted servants, who, after the Revolution in 1689, for political reasons found it safer to live in the North. Soon after becoming possessed of the estate, Colonel Grahame began to make alterations to the hall, and, to create the gardens, he called in the assistance of M. Beaumont, a pupil of the famous French gardener Le Notre. In the house there is an old portrait of Beaumont, whereon is the inscription 'Monsieur Beaumont, Gardener to King James 2nd and to Coll: Js. Grahame. He laid out the gardens at Hampton Court and at Levens.' It is probable that at Hampton Court he worked in the capacity of a foreman."

#### THE GARDENS

were commenced about the year 1700, and a letter written in 1701, describing a great storm that took place in the autumn of that year, tells of the terrible havoc wrought amongst the newly-planted trees. We are able to form a very correct idea of the appearance of the gardens at this date, for there is fortunately preserved in the house a plan of them dated 1720, which shows that, with the exception of a few alterations on that part of the garden south of the bowling-green, every path and hedge remains as originally planned : this is probably a unique instance in England. Even the topiary work, though, of course, considerably grown, still retains its character, and many of the trees are believed to have been planted when large enough to have been partly shaped into the forms they were intended afterwards to present. . . . Whatever may be one's feelings with regard to the use of topiary work—and many will think it is used to excess at Levens—the old-world aspect and great variety of their different forms, if not beautiful, is intensely quaint and interesting. At one corner stands the King with his crown upon his head, and opposite, the Queen with her arms akimbo ; here a crowned lion with a fine tail, there an archway or a gigantic helmet, an umbrella-like construction shading a seat, Queen Elizabeth with her Maids of Honour, and many another creation in Yew standing out with its wealth of deep green foliage amidst the flowers, with walks of soft green turf between the beds. Near by are two quite small enclosures with substantial hedges surrounding them, and overlooked by the old gardener's house, still known as 'Beaumont Hall.' A broad walk separates the flower garden from the kitchen gardens, and at one end is an old Yew arbour known as the Judge's Wig." The price of the three complete parts, in portfolios, is £3 13s. 6d. net ; or, bound in half-morocco, £4 4s. net.

**Children's Gardens.**\*—We must confess to a keen sense of disappointment in reading this book, and cannot discover any good reason for

its publication. A children's book has still to be written, and we are not sure that such a book is wanted, especially one that treats of such subjects as budding Roses, and certainly all botanical names should be studiously avoided. The book is merely a beginner's guide, and not very good of its kind. The truth is we are getting overdone with works of this nature, mere impressions, without the author showing any real knowledge of the subject. Because one loves a garden that is no reason why commonplace thoughts should be transmitted to well-printed pages bound in a pretty cover. We are sorry to write this, as we feel sure the author is quite sincere ; and to a few, those who are personally acquainted with her in particular, the little book may be useful. The child should be taught to love gardening through the flowers of field and hedgerow, and not worried with such a sentence as this : "A charming sweet-scented plant, which will flower on a wall in the winter or very early spring, is *Chimonanthus fragrans*." We feel sorry for the child who has to master such a lesson. Why not, at any rate, tell the child that *Chimonanthus* is "Winter Sweet." On page 11 *Daphne Mezereum* is the sweet-smelling shrub a child should be taught to call the "Mezereon." The use of botanical language might have the evil effect of making the child regard gardening as a mystery impossible to fathom, a school in which simple language is mixed up with names as unfamiliar as sanscrit ; and to give advice about budding a Rose is unwise. In the first place, Rose budding is an operation demanding skill and watchfulness, lest in holding a sharp knife carelessly personal injury is inflicted. If the book had been written with the same feeling as expressed in the following lines, it might have proved a more sensible and worthy production : "Although spring and autumn are the busiest seasons, yet I think I have shown how much you can find to do all through the summer months ; but there will be days of idleness too, hot sultry days, perhaps, when you see the leaden clouds coming up, and feel you need not expend your energy in watering, as the heavy raindrops will soon do it so much better. Then it is pleasant to sit and watch the flowers, and the busy bees, and the white butterflies fluttering round. The flowers themselves keep regular hours. They are not wide-awake all the twenty-four hours of each day. Some of them go to bed very early—long before the sun has set they fold up their petals for the night ; others wait till the dew is falling, while others choose that time for waking up." Simplicity must always be the keynote of children's books. But we would rather take the child to hedgerow and mead there to receive its first lessons in the lap of the greatest of all teachers—Nature herself. The illustrations are unsatisfactory. One is called "*Phlomis fruticosus* and *Spinæa Aruncus*," not a childlike inscription ; and we must remind the author that it is *Phlomis fruticosa*. "A Wattled Summer House" is not likely to appeal to a child, except to have tea in on a summer day ; but we have written sufficient to show that "Children's Gardens" has so many defects that we honestly cannot recommend it.

#### SPRING FLOWER SHOW AT PIETERMARITZBURG, NATAL.

This show was held in the Governor's elegant ball-room on October 16. There was a very fair display and a considerable amount of competition. The readers of THE GARDEN may feel interested in knowing what their kinsmen in this far distant part of the British Colonies exhibit at a spring flower show. Daffodils and the many bulbous flowers we associate with spring flower shows in Britain have no place here. I have, however, induced Mr. J. Medley Wood and his clever cultivator, Mr. James Wylie, to make a start with Daffodils in the Durban Botanic Gardens. Their natural fear of success arises from the winters being comparatively rainless and their summers somewhat wet. Pietermaritzburg is some 2,000 feet higher than Durban, still almost rainless in winter

Yesteray I had a long walk on the hills : the ground was, however, so dry that few flowers were to be seen, but on the way up from Durban were some magnificent specimens of Brunsvigia Josephine with last year's flower-heads still on them. Cyrtanthus angustifolius, a most charming scarlet species, was in full flower ; and large quantities of the pure white Drimia, better known, I suppose, under the name Sparaxis pulcherrima alba. This is the prevailing species from the coast line to a certain elevation, when the colour changes to rose, purple, and almost black. Returning to the flower show, occupying one end of the ball-room (the room somewhat dark for a flower show, especially as the day was dull ; on a bright day the light might be all that could be desired) was a collection of large well-grown specimens of Ferns from the garden of Sir B. W. Greenacre, K.C.B.

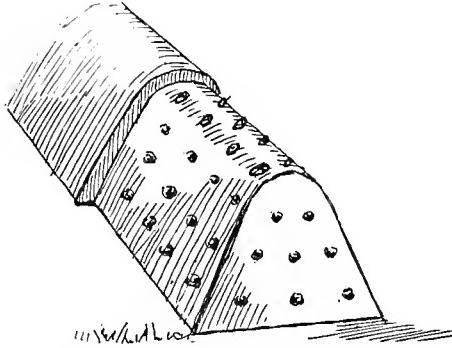

Along the stages on the left from this fine group of Ferns was a small collection of Begonias, mostly Rex varieties ; then three competitions for the best six varieties of exotic Ferns. Amongst these were some really well-grown specimens, but rather small. Following were four collections of indigenous Ferns, six species of each, amongst them being some familiar types, but very few of them were well grown. Then a collection of indigenous plants in pans, &c. ; they were not at all flattering to the skill of the exhibitor, amongst them *Gilia aurantiaca*, which should make a good pot plant, dwarf in growth, and the flowers a rich orange-scarlet : a small *Albuca*, I could not learn its name ; a poorly grown *Clivia*. The others of no account.

Pansies and Violas in pots and pans, none of them showed breed or cultivation. Then a fine well-grown specimen of the yellow spotted large *Coltsfoot*. The novelty of the show, however, was a single crown of *Lily of the Valley*, with two small spikes of fair-sized bells, this being the first time the flower had been exhibited in Pietermaritzburg. Had it been a pot with ten or twelve crowns there would have been some effect. At Durban *Lily of the Valley* will not flower, but in the higher part of Pietermaritzburg evidently it may be got to do fairly well. Three well-grown pans of *Selaginella* were conspicuous. A table of mixed plants, well staged but rather crowded, attracted attention ; Mr. W. J. Bell, florist and seedsman, had a good table of assorted cut flowers and plants, amongst the cut flowers being *Lilium Hartii*, *Mikado Poppy*, *Hunnemannia* and many others. There was a good show of Roses and many competitors, but there were few really good flowers, owing, I was told, to the unusually dry winter months. Some varieties, however, had stood the drought better than others or had more care, and it was these few good flowers which redeemed the exhibits. Table decorations were not good, but the space limit was against the exhibitors displaying much taste. At Cape Town better results were obtained, as each exhibitor was allowed—as in London—a table. One exhibitor of Daisies made a pretty design with these flowers in letters DAISIES, and edged the frame with the same. The flowers were the English Daisy, Marguerites, and Chrysanthemum coronarium. Ladies' sprays were just passable ; crosses and wreaths were generally good ; buttonholes for dinner table were also pretty.

An arch and gate ajar were in really good taste, but a double-span arch did not come out at all satisfactorily. Baskets of indigenous flowers ; only one of the group showed any taste. It was conspicuous for *Crinium longiflorum* and *Gladiolus aurantiacus*. The collections of Pansies and Violas shown on cut circular papers were very poor in breed and size of flower. Double and single Petunias staged on cut circular papers were pretty. *Phlox Drummondii* was generally poor. Some really good specimens of Shirley Poppies were staged in glasses. Ten week Stocks very good. A few of the Sweet Williams staged were good. Verbenas very poor, which was surprising, as the plant is a great success in Natal. Collections of ordinary garden flowers fairly good and representative, *Mignonette*, *Eschscholzia* all in a glow, Poppies, Sweet Peas (not Eckford's fine varieties)

\* "Children's Gardens." By the Hon. Evelyn Cecil. Published by Messrs. Macmillan and Co. Price 6s.

Salpiglossis, Cornflowers, Indian Pinks, Snapdragons, Coreopsis, Cosmos, Gaillardias, Candytuft, Cannas, Larkspurs, pot Marigolds, and white Marguerites were conspicuous; besides these were many others of our common garden annuals. Bouquets generally were far too lumpy, both as regards Rose or mixed bouquets. The redeeming features amongst these were three by Mr. J. W. Bell, florist; one, yellow Roses, each flower gracefully drooping, and intermingled with the small

MUSHROOM BED WHEN FIRST MADE AND SPAWNED.  
(The second portion is moulded over with soil.)

Maidenhair Fern, also a graceful spray bouquet, and yet another, to each of which a first prize was awarded.

A collection of wild flowers was staged in glasses, the principal of which were as follows: White Drimia, small cream-coloured Gladiolus, Streitzia augusta, Gladiolus aurantiacus, Cyrtanthus angustifolius, Burchellia capensis, Senecio concolor, Lasiospermum, Cyrtanthus McKenii, Orthogalum thrysiflorum, Hedyotis, Crotolaria, Greyia Sutherlandi (Natal Battle Brush), Thunbergia natalensis, Crinum longiflorum, Jasminum, Pink Diarama, Cyonium tabulum, a beautiful white-flowered parasite, but, like Harveya, all efforts to propagate it have failed.

There was a small collection of fruit, mostly Citrons. Two dishes of good-looking Strawberries, but the dishes represented the smallest and largest fruit, showing that the exhibitor had no idea of grading, only of quantity. The collection of vegetables was small. Some very good Beet, but Lettuce, &c., poor.

PETER BARR, V.M.H.

Pietermaritzburg, Natal.

## THE KITCHEN GARDEN.

### MUSHROOM GROWING IN GARDEN, FIELD, AND COTTAGE PLOT.

**A**MONG the vegetables produced in garden or field the Mushroom is one of the most popular, and this popularity is not confined to one class. The difficulty is to obtain the article in a fresh condition and in sufficient quantities at a moderate price. This latter difficulty places the Mushroom entirely out of the reach of the masses of the people for certainly ten months out of the twelve, as except during September and October, when they are plentiful in some seasons in the fields, the price otherwise is prohibitive, being never less than 1s. per lb., and this not for fleshy, fresh British-grown Mushrooms, but for thin, dry, and hard French ones, only fit for soups and flavourings. It must not be inferred from the above statement that there are no Mushrooms grown in England on commercial principles, as the reverse is the fact, and so much are those fresh Mushrooms appreciated that they are immediately disposed of to regular customers at handsome prices at local markets where grown.

The Mushroom is a native of Britain, and can be grown here to a greater perfection than in any other part of the world, either out of doors in our fields, or under artificial conditions in houses specially prepared, or on the out-of-door system as practised by market garden growers.

With regard to our natural field crops in autumn after a hot summer, followed by warm and heavy showers of rain (on most of our warm and properly drained meadow lands), the valuable Mushroom comes up in generous quantities, and that without the help of man; indeed, as a welcome gift from the lap of Nature, a gift of late years which has helped the farmer more on many occasions to pay the rent than has the ordinary cultivated crops of the farm. It is a moot question, but beyond the province of this work as to whether field Mushrooms cannot be grown profitably, it is well worth a trial, and is a hint to the Chamber of Agriculture and others interested. The cultivation of the Mushroom is dealt with from four different standpoints: (1) The professional or private gardener; (2) the amateur; (3) the market gardener; and (4) the cottager, closing with a few hints as to successful methods of field culture, with a chapter of instructions of how to manufacture Mushroom spawn.

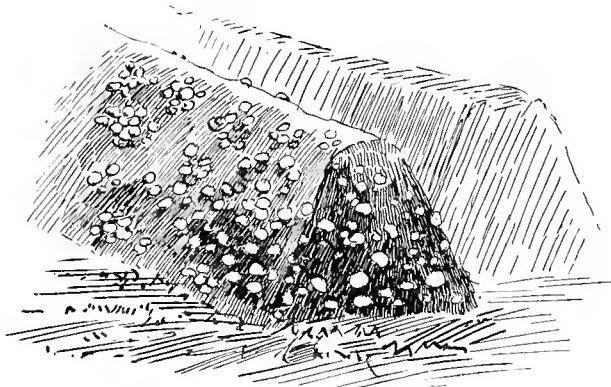

In the homes of the rich there are for the most part the necessary materials for producing satisfactory crops in every season of the year, and managed as these gardens are, by highly trained and experienced gardeners, it would seem superfluous to offer any remarks for their guidance on the growing of Mushrooms. Simple as it may seem to the inexperienced, the Mushroom is an erratic crop. The young horticultural student earnestly endeavouring to qualify himself at some future time, not too remote, let us hope, for a responsible head gardener's position will find a knowledge of Mushroom growing amongst the most useful of his acquisitions, as in good and well-equipped gardens Mushrooms are in urgent demand and expected almost every day in the year, and failure in the supply often makes matters very unpleasant for the gardener. Our first consideration must be the

**MANURE AND ITS PREPARATION,** the two fundamental principles on which success or failure rests. With regard to the most suitable manure, horse manure is the best, and if good results are to be obtained the manure from corn-fed animals when little or no drugs are given should be chosen. Manure from heavily drugged horses is absolutely of no use for successful Mushroom growing, and this is one of the important points to notice. With regard to stables in private establishments this precaution is not so necessary, but where London or any other city's stable manure is the medium the grower cannot be too careful as to the quality of the manure he has to deal with.

The Mushroom grower must be on good terms with the coachman or the man in charge of the stables, who will separate the manure of sick horses, and in this way prove a good friend. Some stables are provided with a covered roof over the manure yard, and, where this is the case, it will be sufficient if the stable manure is fetched away every three days, and

must be taken away in the rough, long and short together. Where this provision does not exist it will be better to fetch the manure away every day, or at least every other day, and place it in a dry, open shed in the garden, as on keeping rain away from the manure depends much of the ultimate success of the crops. Whether it is decided to clear away the manure daily, every other day, or twice a week, let it be delivered, if possible, into a dry, open shed, where there is a free circulation of air, or, minus an open shed, in some sheltered, dry, and airy corner of the garden, where it can be protected and turned over, and the extra moisture liberated until it is dry enough to place in a heap to undergo slight fermentation. The first thing to do with the long and short manure from the stables is to turn it over with a three- or four-tined fork. A fork of this width will admit of all the actual manure falling through by slightly shaking it, as well as much of the short, littery straw. This is all we want from the manure for the purpose of making Mushroom beds, the long straw being laid on one side for other purposes, when it will be most useful, especially when the market garden aspect of Mushroom culture is dealt with. The next process after the manure is properly shaken out from the rough straw is to lay it out on the floor of the shed at an even thickness of about 7 inches in order to expose it to the air for the purpose of drying, and also to cause a very slow and almost imperceptible fermentation. Every load delivered must be served in the same way, and the whole turned over with the fork about every three or four days in order to liberate any rank gases generated. After undergoing this process for about ten days or a fortnight the manure will be fit to throw together into a large heap to cause further fermentation, thereby reducing the heat of the manure to the temperature of 80° or 82° Fahr., when it will be of a safe and proper temperature to form into beds in the Mushroom house proper or wherever else it may be proposed to construct the beds.

Upon the careful preparation and the proper condition the manure may be in at the time the beds are made up depends to a larger extent than on any other particulars the success or otherwise of the crops. It is a well-known fact that Mushrooms abound in

MUSHROOM BEDS OUT OF DOORS IN BEARING.

nitrogen. It is also well known that nitrogen is found in considerable quantities in the manure of horses, therefore in subjecting the manure to fermentation there is danger if this process is overdone of the nitrogen escaping in the way of ammonia to the great detriment of the manure

and the subsequent crops. The chief lesson to be learnt from this is to be careful to prevent at all costs too rapid a fermentation and the consequent high temperature. By adding, say, two barrowloads of soil to the cartload of manure and well mixed before the manure is formed into a heap for the purpose of fermentation, this mould will answer the useful purpose of absorbing the nitrogen, preventing its escape, and preserving it for the mushrooms later on. The manure after being placed in a heap as advised should remain so for, say, three or four days. If not overdry when put up three days is sufficiently long enough, but if moderately dry four days is not too long. The safest and best plan is to put a trial stick in the heap, one long enough to reach to the centre, say, 3 feet deep. It should be examined on the second and every subsequent day, and if the stick becomes in any way too hot for the hand to bear the heat must be opened out at once and the manure spread out for a few hours to cool, and afterwards put up again in the same way, and the same precautions taken with the trial sticks, &c., as regards heat, and if still too high the heap must be opened out again to cool and reformed in the course of a few hours as before, when it will be found that the heat will have dropped to about 85° or 90°, and ready for forming the beds. The fact of opening up the manure again in removing it to the mushroom house will further reduce the temperature a little, bringing it down to about 80° or 82°, which, as I said before, it should be at the time the beds are formed. Before leaving the important subject of the manure let me again reiterate the vital points to observe in its preparation if the best results are to be obtained—rain to be kept off; expose to the air in thin layers in a shed to dry surplus moisture without undue fermentation. When this process has been carefully attended to fermentation afterwards, when the manure is formed in a heap as advised, is much less violent and more gradual, thereby reducing the loss of nitrogen by the escape of ammonia to a minimum. In this way not only are heavier crops of better mushrooms secured, but the beds will last in bearing half as long again as will those formed from manure which has been overheated and put up wet. The latter conditions are undoubtedly accountable for more failures than most people are aware of. I must here mention that those who aspire to grow mushrooms under artificial conditions such as we are now considering, and who have only a limited quantity of manure to deal with, must not wait until a large heap is collected together sufficient to form a good-sized bed, because if they do that manure first collected would be overspent and practically useless before a good-sized heap could be got together. Therefore the bed must be made up in small sections at a time as the manure is got ready, and this is really an advantage than otherwise, as a moderate and well-sustained supply is secured rather than a glut at one time and scarcity at another.

#### HOW TO FORM THE BEDS.

The system now under consideration is the one followed in private gardens where a proper house is available for the purpose. The house is generally a lean-to with a north aspect, situated at the back of vineries, &c., or of a garden wall, and no better position could be found. If it is sunk below the ground level so much the better, as being less subject to fluctuations of temperatures and more easily kept in a humid state. The beds should be formed on either side with a path in the

middle, and 3½ feet wide is the most convenient width for the bed. The depth should be 9 inches. The best material to form the beds with is stone, brick, or slate, but not wood or anything perishable. It is then well under the grower's control in respect to gathering the mushrooms.

(To be continued.)

#### FOREIGN NOTES.

#### THE DODECATHEON.

**T**HE natural order Primulaceae contains many beautiful plants which are always much sought after by lovers of the garden. They are legion, and, with the exception of a few undeservedly despised and almost forgotten kinds, are all in great request. Amongst this number is the Dodecatheon, a hardy perennial. What grace there is in its drooping flowers on stalks which stand clear of the foliage! The name, derived from the Greek, literally means Twelve Gods. The great botanist, Linnaeus, who first described this plant, alluded to the beauty of the flowers, and to the number generally found upon the same stalk. Of course this is far from being the exact number in every species: we have often counted from fifteen to twenty upon the same stem. The shades of colour are not very numerous, and they vary from red-purple to pure white. The flowers have a vague resemblance to those of the Cyclamen (another genus of Primulaceae), but with this great difference, that the flowers of the latter are isolated.

There are many species and varieties of Dodecatheon; most of them are rather delicate in the North, and require a covering during the winter. Dead leaves or short straw may be used for this purpose; this covering can be kept in position against the wind by branches or by long manure. The plants should be carefully labelled, for they lose their leaves in winter. They should be cultivated in leaf-mould, with the addition of a little earth and sand. A partly shaded position especially suits them. The position of the plant must be changed at least every third year, and the removal should be taken advantage of to divide the tufts; these should be at once replanted in a new and carefully prepared soil, the operation being performed when the coverings are removed in March, or about the month of September. The Dodecatheon is also increased by sowings made in autumn on cold beds covered with frames during the winter. The young plants should be planted out in the middle of April. Although Dodecatheons like moisture it is well to drain the soil in which they are planted, for stagnant moisture may cause the stems to rot.

In a word these hardy plants are not much more difficult to grow than others, provided the gardener does not omit to bestow upon them the trifling care of which we have just spoken. The species which is sometimes still met with in amateurs' gardens is Dodecatheon Meadia. From the centre of its root-leaves springs a stalk some thirty or forty centimetres high, carrying about twelve drooping flowers of a red-purple colour, and with their petals erect exactly as in the Cyclamen. D. integrifolia and D. Jeffreyi have been used by seedsmen to produce interesting hybrids, of which the names are given below. The first of these bears flowers of a lilac-pink or purple colour, the second has flowers of the colour of carmine.

The following is a list of Dodecatheons known to commerce or in botanical gardens:—

D. Media (Lin. North America), divisions of the corolla very erect, purplish pink, with green spots; D. Meadia var. brevifolium (Gray), D. M. lancifolium (Gray), synonymous with D. Jeffreyi (Hortus), Rocky Mountains, larger flowers, bright pink with spots; D. M. macrocarpum (Gray) synonymous with D. giganteum (Hortus); D. M. splendidum (Hortus), D. M. cervileum, D. M. laciniata (Florin), D. M. albiflorum (Hortus), D. M.

lilacinum (Hortus), D. M. elegans (Hortus), D. M. trigidum, D. M. hortense. Some thirty varieties have sprung from these; such a collection is but rarely met with. There is also the D. Cleveland (Greene), an American variety; the D. integrifolia (Michaux), United States; D. Lemoinei (Lemoine) and its varieties, D. L. atropurpureum, D. L. compactum, D. L. elegans, D. L. excelsum, D. L. robustum; all these varieties were produced by Lemoine of Nancy; D. pauciflorum, introduced by the same grower; D. Hendersoni. There are charming plants among this large collection of Dodecatheons: it is surprising that we so seldom see them in gardens.

AD. VAN DEN HEDE in *Bulletin d'Arboriculture*.

#### SOCIETIES.

##### NORFOLK AND NORWICH HORTICULTURAL SOCIETY'S CHRYSANTHEMUM SHOW.

This show, a three day fixture, is held usually at a late date considering the surroundings, being held this year on the 20th, 21st, and 22nd ult. The venue is the grand old hall of St. Andrews and the adjoining one of Blackfriars. Taking a general survey of the exhibits (in spite of predictions of a bad time expressed by the usual grumbler type owing to the wet season), these surpassed last year in many things. This was especially noticeable in the stands of Japanese cut blooms, and also in the fruit section. Sir Saville Crossley took the premier award for a stand of forty-eight well-finished blooms, and also a charming two dozen stand of incurves, having in this latter the medal bloom, a massive specimen of Mine. Ferlat. The medal for best Japanese was secured by W. R. Seago, Esq., Lowestoft, with a bold well-balanced flower of Kimberley. Lord de Ramsey, Lord Walsingham, and the Hon. A. E. Fellowes, M.P., were also prominent prize winners in the cut bloom classes. The best plants of Chrysanthemums in pot were those sent by A. J. Bunting, Esq., Old Catton, having bold blooms, with stems well covered with good healthy foliage. H. Rider Haggard, Esq., secured the first prize in all three classes for Orchids, staging some very choice Oncidiuns. Mr. W. Altan, gardener to Lord Suffield, had grand specimens of Grapes and Pears, securing the chief prizes; whilst for vegetables, Mr. G. Davison, gardener to Captain Petre, Westwick House, could fairly claim champion-ship by the large percentage of firsts ticketed on his exhibits. This exhibitor also had the best nine dishes of cooking Apples, and grand samples they were. One of the most striking features was a bank of Chrysanthemums grown in pots and exhibited in a massive bank by Mr. Robert Holmea, a specialist of Tuckswood, Norwich; it covered 55 feet long by 6 feet wide, and embraced over 250 different kinds. Messrs. Daniels Brothers, Limited, had a display of much merit, consisting of cut blooms of Chrysanthemums, pot plants, fruits, and sundries. Hobbies, Limited, had a bank of the leading exhibition Chrysanthemums set up in bold array, also some pretty bunches of Roses from their fields.

##### EAST ANGLIAN HORTICULTURAL CLUB.

At the November monthly meeting Mr. J. Clayton, manager to Messrs. Daniels Bros., Limited, read an interesting paper, entitled "The Four Seasons of the Year: Notes Taken in a Garden." Messrs. T. B. Field, F. Piper, J. W. Clarke, and others engaged in an interesting discussion, pointing to the gardener's opportunity of comparing with the open book of Nature before him the works of his Creator.

##### BRISTOL AND DISTRICT GARDENERS' ASSOCIATION.

THIS up-to-date society held a well-attended meeting at St. John's Rooms, Redland, on the 27th ult., Mr. E. Poole, F.R.H.S., occupied the chair. The subject for the evening was "Fungi," the lecturer being Mr. Harding, of Clifton, and it need hardly be said that his lecture was a most instructive one, and thoroughly appreciated by his very attentive audience. He divided his lecture into four heads, namely: Moulds and mildews, rusts and smuts, galla and blisters, canker and dry rot, each head receiving careful consideration, his remarks being followed with no small amount of interest. Mr. Harding pointed out the extreme beauty of fungi when under a powerful microscope, many of us being apt to look upon them as very ordinary every-day things, simply for the want of knowledge of these natural beauties, the colourings in many being almost unsurpassed. He gave information as to the ways and means of fungi being introduced, one specimen alone being capable of spreading millions of spores, pointing out that they would only flourish where the conditions suited their requirements. He fully described the Potato and Tomato disease, which at times were very troublesome to the gardener. Altogether his lecture was highly instructive, and he was unanimously accorded the hearty thanks of the meeting. His lecture was much enhanced by 150 water-colour drawings, very kindly lent by Mr. Wheeler, Queen's Road, Clifton, which, to say the least, were beautiful in the extreme, and he was voted the sincere thanks of the association for his kindness. The prizes for the evening were for a vase of autumn foliage and berries, for under gardeners only, the prize-winners being Messrs. Keeford, R. Poole, and A. Coombs. A certificate of merit was awarded to Lady Cave (gardener, Mr. Poole), who takes such a kindly interest in the doings of the association, for a Pineapple and a collection of fungi, one also being awarded to Mr. A. Cole (gardener, Mr. Bird) for a fine bloom of Flurense Molynex Chrysanthemum.

## TREES AND SHRUBS FROM JAPAN.

**A**MONG the more important lectures delivered before the Royal Horticultural Society during the year that is fast drawing to a close was that by Mr. James H. Veitch on "The Lesser-known Trees and Shrubs of Japan," and those present will remember the exceptionally interesting collection of dried and living specimens from the nursery of the firm at Coombe Wood, Kingston.

At this planting season, and at a period in the history of English gardening when there is a greater desire to think as much of the woodland as of the flower border, the remarks of Mr. Veitch should not be forgotten. To plant recklessly the more recent additions till they have proved their worth for this climate would be foolish and expensive, but those able to do so may well make trials with a view to further plantings in the future. It may be urged that our beautiful native shrubs are not planted in the free groups we would have them seen, and certainly no foreign shrubs can compare with or take the place of our Yews or Hollies. However large a collection of exotics may be, a winter walk among them only shows that there is nothing more cheerfully handsome than our Hollies or more solemnly dignified than our Yews. But this does not mean that the beautiful species from Japan and China should not take a proper share in garden adornment.

To show the wealth of the flora of Japan, Mr. Veitch mentioned in his lecture that at one place, at an altitude of 500 feet above the sea level, Professor Sargent had found no less than forty-six species and varieties of plants, and, within a five-mile radius, sixty-two, though, as Mr. E. H. Wilson, who has recently travelled in China, has proved, many of the trees and shrubs found in Japan are also natives of China.

We have studied the lovely species from China and Japan with much interest, and those who visit regularly the shows and meetings of the Royal Horticultural Society have opportunities of seeing living specimens in either leaf or flower, and therefore in a measure find out for themselves their value for English gardens.

Our visits to Coombe Wood to see the introductions from abroad in health and vigour have been of extreme interest and utility, and it is astonishin

the better-known species

are not more planted in English gardens, though their hardiness has been proved by long experience.

It may be useful to point out a few of the shrubs that we seldom find mentioned in books or journals, but yet possess great flower beauty. One is *Viburnum tomentosum* Mariesi, a quite distinct species, and so graceful that a large group on lawn or in woodland would be an unfailing delight during the time of flowering. It is allied to the well-known *V. plicatum*, but with this great difference—that the sterile flowers are confined to the outer portions of the inflorescence. This imparts a quaint beauty to the shrub. Its spreading shoots are lined with the flat cymes, and the whole bush a mass of cream-white, more pleasurable even than the wealth of ivory clusters of the better-known *V. plicatum*.

The *Styrax* genus illustrates the slow appreciation shown for good hardy shrubs from Japan. *S. Obassia* has been in the Coombe Wood nurseries for many years, flowering with delightful freedom in its appointed season, but we have not seen a tree of either this or any other *Styrax* elsewhere. Professor Sargent, in *Garden and Forest*—a journal whose brief life we have never ceased to regret—writes of this species thus: "As an ornamental plant the most valuable of this family (*Styraceae*) as represented in Japan is certainly *Styrax Obassia*, a tree which grows as far north as Saporō in Yesso, and which may therefore be expected to be as hardy as *Cercidiphyllum*, *Magnolia Kouba*, *Syringa japonica*, and other Yesso trees with which it grows and which flourish in New England." *S. japonica* is another beautiful species which makes the hillsides of Central Japan white with flowers in the month of May, and has proved quite hardy in this country.

Mr. Veitch alluded to the Japanese Maples, and *A. distylum* in particular, as a noble tree. From what we have seen of this species we shall not be surprised to find it in the near future much planted in English gardens. It was introduced by the firm from the high mountains of Nippon, and Messrs. Veitch's description is an apt one: "The foliage is very distinct, being composed of single ovate acute leaves, with finely serrate margins, 5 inches to 7 inches long and 3½ inches to 4 inches broad, green above, paler beneath, and quite glabrous except at the base and the axils of the larger nerves. It is perfectly hardy in Great Britain, and a highly ornamental tree for park or pleasure ground."

*Cornus macrophylla*, *C. brachypoda* variegata, and *C. Kousa* form a charming trio of introductions from Japan, but they are as rare as a species brought to this land a week ago. *C. macrophylla* flowers superbly at Coombe Wood, the branches almost bent with the burden of blossom. Professor Sargent wrote of it as follows in *Garden and Forest*:—"It is one of the most beautiful of Cornels, and in size and habit the stateliest and most imposing member of the genus. In Japan, trees 50 feet or 60 feet in height with stout, well-developed trunks more than a foot in diameter are not uncommon, and when such specimens rise above the thick undergrowth of shrubs, which in the mountain regions of Central Japan often cover the steep slopes, they are splendid objects, with their long branches standing at right angles to the stem and forming distinct flat tiers of foliage, for the leaves are crowded at the ends of short lateral branchlets, which grow nearly upright on the older branches. These are 5 inches to 8 inches long and 3 inches to 4 inches broad, dark green on the upper-surface and very pale, sometimes nearly white on the lower surface." *C. Kousa* is another species well worthy of the planter's attention, and many other instances might be given of the strange neglect of trees and shrubs of great charm and distinctness introduced of late years from Japan. That excellent Birch (*Betula Maximowiczii*) will, as Mr. Veitch said, prove "better than anything we possess," and a great future is predicted for the Japanese Oaks, deciduous and evergreen. *Quercus dentata* grows to a height of 80 feet in these eastern forests, and the evergreen *Q. acuta*, *Q. cuspisata*, and *Q. serrata* were much praised for their noble leaves and spreading growth. *Daphniphyllum glaucescens* is an evergreen that is slow to win the regard of the planter, but few handsomer evergreens exist; it is quite hardy, leafy, and just the shrub for the lawn.

Of the good work accomplished in recent years, to say nothing of the past, by Messrs. Veitch in bringing home the plants of permanent value for this country, we need not write; it is evident in the gardens of the British Isles, and the outcome of the earnest endeavours of such travellers as Mr. James H. Veitch himself and the firm's collector, Mr. E. H. Wilson, while quietly working for our good have been men of the rare quality of Dr. Henry, who has enriched our collections with many things we now regard as flowers for all gardens. Nor are we unmindful of the work accomplished at Kew, apart from purely botanical

considerations, in planting these beautiful introductions in ways to reveal their value for English gardens. They are planted in border and woodland, and thus we know their value for similar places in private domains. This is a practical phase of gardening we rejoice to find carried out ungrudgingly at Kew in spite of the increasing smoke and dirt from the fast encroaching Metropolis.

### THE HORTICULTURAL HALL.

#### IS RECONSIDERATION POSSIBLE?

SIR,—As one of the many Fellows who have the interests of the Royal Horticultural Society at heart, I wish to express the hope, if I may be permitted to do so in your pages, that the design for the hall that has been published is not the final pronouncement of the council's opinion as to a suitable building by which to commemorate worthily the society's centenary.

I cannot help being aware that, in many cases besides my own, in all those in fact with which I happen to be in friendly or accessible contact, that the proposed design is viewed with entire disfavour, in some with absolute dismay. We say to each other—is it possible that that is the best that this now great and powerful society can put forward as the expression in architecture of its aims and position! We think—with bowed heads—how our French friends, with their admirable taste in matters technical, will laugh at us! We think and say all kinds of things that for courtesy sake we dare not disclose to the building committee of the Royal Horticultural Society. One thing only by your permission I will say for myself and for the others whose minds I know—that we earnestly trust there may yet be time and willingness to reconsider the whole matter.

It would be easy to heap abuse on the unhappy plans themselves, but this is not my desire or intention, only to give expression to the earnest hope that they are not finally accepted.

Your present correspondent is not an architect, but has been long in touch with matters of structure and design. One writer in *THE GARDEN* suggested an added porch as an improvement to one face, but no added ornament can redeem a poor design. In architecture the whole design in its unity expresses dignity or expresses meanness, or anything between, unless, as is, alas! so often the case, it expresses nothing at all. It is not added ornament that makes a beautiful building, but good design and proportion from the very beginning.

In these plans, moreover, one cannot help observing many examples of opportunity wasted, such for instance as rather obvious ways of making the hall not only better suited for its own purpose, but of rendering it more attractive and better adapted for letting purposes for many kinds of social gatherings; for it is to be presumed that as shows are held only fortnightly it will be available for other purposes, to the evident advantage of the society's finances. There might also be ways of offering greater convenience and comfort to exhibitors, and of safeguarding the entrance of tender plants in cold weather, and so on.

It would have been easy to write an appeal direct to the building committee, but one letter to their office would be but a drop in the ocean, whereas in your pages it may be of more utility as showing others what some fellow members feel, in order that they may, as I trust they will, desire to take part in an appeal, in all friendly courtesy, to their society's building committee.

F.R.H.S.

SIR,—It may be, on the whole, a wise exercise of editorial discretion not to invite a general discussion of the proposed plans for the new hall, but the interests involved are large and important, and the particular plans adopted may make or mar what should be an enterprise worthy of the Royal Horticultural Society. Whether preferring, first, the garden or the hall, we must all feel that, the latter having achieved precedence, the society should have something worthy of the occasion, and justifying the very large expenditure which is to be incurred. That the plans shown to us have been received by many with feelings, to say the least of it, amounting to very great disappointment, if, indeed, not to actual dismay, is no secret in the horticultural world. "Cannot the plans be stopped, or at least further considered and amended if good cause be shown?" is a question which has been frequently heard amongst Fellows of the society. Surely, looking at the fact that some £40,000 will have to be expended in the erection of the building, and that a yearly increased expenditure is involved, which, capitalised, would mean an additional sum of £33,000 or thereabouts, in all fully £70,000, it would be far wiser that a little delay should now be accepted as inevitable than that the society should hereafter lament at leisure over a lost opportunity.

If by the term "approved" the council mean that they have irretrievably committed the society—and without reference to the Fellows—to the plans in question, and that it is now too late to consider any suggestions for the improvement or modification of the particular design, exterior or interior, then I think that a serious responsibility has been incurred, and one which must in the future continue to attach to the members of this particular council. It is the view of many that in an event of this importance the design and plans should have been put up to public competition. Has this been done, and if not, why not, and is it yet too late to resort to this usual method? The expenditure of a few hundred guineas in this direction is a trivial consideration in view of the large sum involved in the undertaking. And again, would it not be well that before final adoption the competitive plans should be submitted—not for final selection, but for advice or suggestion to the council by eminently capable and competent men—to a grand committee of all the members of the several standing committees of the Royal Horticultural Society? If the present plans are adopted and carried out without, as would be the fact, opportunity afforded to the Fellows to criticise and suggest, then in my opinion worse than a tactical mistake will have been made. We shall have a building poor in architectural design, and absolutely inconvenient and insufficient in its interior arrangements, not least of which will be committee rooms inadequately lighted for critical examination of the flowers submitted, and removed so far from the actual place of exhibition that reference for purposes of comparison to blooms contained in general exhibits will be from consideration of time and distance practically impossible. Where again is the room large enough to accommodate in general meeting the members of a society numbering over 6,000, and where the homes in the building for the special societies, such as the National Rose Society and National Chrysanthemum Society? And all these things have been foreshadowed, even when the probable expenditure was estimated at little more than half the large figure to which it has gradually grown. *Festina lente* is a proverb worthy of consideration.—I remain, sir, yours faithfully,

A FELLOW OF THE R.H.S.

[Though we desire no bickering discussion the above letters are so sincere and to the point that we gladly publish them.—ED.]

### NOTES OF THE WEEK.

#### FORTHCOMING EVENTS.

December 15.—Meeting of the executive committee of the National Chrysanthemum Society.

December 16.—Annual meeting of the National Dahlia Society, Hotel Windsor.

**"The Garden" Almanac.**—We shall publish with the first number of the new year an almanac for 1903, containing the dates of all the principal events in the horticultural world for next year. The almanac issued this year was a great success, and the forthcoming production will be even more useful to gardeners and all interested in forthcoming horticultural events.

**Coloured plate of Tea Rose Lady Roberts.**—The plate to be given away with the first number of the new year will be of the beautiful Tea Rose Lady Roberts, which aroused much interest during last summer and autumn.

**Mr. Martin Sutton.**—A statue of King Edward VII. was recently presented to the town of Reading by Mr. Martin J. Sutton, and unveiled by H.R.H. Prince Christian. At the same time the freedom of the borough was conferred on Mr. Sutton.

**Rose G. Nabonnand.**—We shall be pleased if we can be of service in settling the correct nomenclature of the above Rose. Having the pleasure of a personal acquaintance with the rosarian whose name it bears, and remembering the Rose from its first introduction, we inserted a note in our catalogue calling attention to the matter, and what we stated there is confirmed by the following extract from a letter we received from Messrs. Nabooand last August: "Le prénom de notre père est bien Gilbert non pas Georges et nous avons nommé cette Rose G. Nabonnand tout court; c'est donc par erreur que les journaux anglais l'annoncent sous le nom de Georges Nabonnand; si vous pouvez leur en faire la remarque nous vous en serons bien obligés." The italics are Messrs. Nabonnand's. It follows, therefore, that the correct name is G. Nabonnand, as stated by us.—WILLIAM PAUL AND SON, Waltham Cross.

**"Index Kewensis."**—It is interesting and welcome news to know that this famous work will soon be completed to the year 1900. The main work was brought to the year 1885, and then a supplement in four parts was promised, the second part having appeared recently. This supplement, which comprises ten years, 1885-95, is being edited by M. Théophile Durand, Directeur du Jardin Botanique de l'Etat, Bruxelles, and the proofs corrected by Mr. Daydon Jackson, Permanent Secretary of the Linnaean Society. The main work was printed by the Oxford University Press, but negotiations in reference to this supplement fell through, though it is gratifying to know that the second supplement, bringing the work to the end of the century—i.e., five years more, is being compiled at Kew, and the first part is almost ready. This great work of the past century has therefore had a somewhat chequered history; but it is being completed almost to the present time, in the best possible place—the Kew Herbarium.

**Chrysanthemum Miss Mildred Ware.**—This is a Japaoese variety, and will probably become extremely popular in succeeding seasons. It was exhibited before the National Chrysanthemum Society's floral committee, and also in the groups of Mr. H. J. Jones and Mr. Norman Davis at the great November exhibition at the Royal Aquarium. It is said to be a seedling from Mme. Carnot, and the flowers remind one of that handsome sort. The colour is just a little difficult to describe accurately. Some call the flower a Lady Hanham-coloured Mme. Carnot, but as a matter of fact, the colour is midway between Charles Davis and Lady Hanham. It is an acquisition, and will no doubt be largely grown.

**Cotoneaster frigida.**—From Dunningwell, Millom, *via* Carnforth, we receive the following note:—"The accompanying berried shoot is a bit of *Cotoneaster frigida*, which I saw growing in this neighbourhood a few days ago. The bushes presented a most gorgeous appearance for this time of year, and were completely covered from the ground to the top with branches heavily laden with glowing crimson berries, very much like those of the Mountain Ash. The evergreen leaves more resembled *Laurustinus*; the bushes were nearly as high as the house by which they grew, and which was nearly surrounded by them, so you may imagine what a picture they made for the very end of November. If this shrub were better known it would certainly be widely planted, because it adds hardiness to its other attractions, and is very easy of culture, besides it is only priced at 1s. to 1s. 6d. in the nurserymen's catalogues."—C. B. MYERS.

**A late-flowering Nerine (N. Manselli).**—The best-known of the Nelines, such as *N. Fothergillii* and *N. sarniensis*, are justly valued as beautiful flowering plants for the greenhouse during the autumn months, but that above mentioned—*N. Manselli*—considerably extends the period of blooming, as it may often be met with well into December, at which time its bright carmine-pink flowers are very welcome. It has now been before the public for some years, but is still far from common, though its merits are so pronounced. It was raised by Mr. O'Brien when at the once famous nursery of Messrs. E. G. Henderson, of the Wellington Road, St. John's Wood (now a part of Lord's Cricket Ground), and the Pine Apple Nursery, Maida Vale. The bulb was, I believe, purchased under another name by Mr. Mansel, of Guernsey, but on flowering it proved to be so distinct that the name of *Manselli* was given to it. *N. vodulata* or *crispia* is quite as late in flowering; it has small bulbs and grass-like leaves, well overtopped by the flower-scape, which bears several blossoms, the segments of which are extremely narrow, much undulated, and pale pink. It is far less showy than many of the others, but its delicate beauty and freedom of flowering are conspicuous.—T.

**Roses in December.**—Few Rose growers can remember a season like the present, when a good gathering of flowers was to be had in November, and stray blooms in December. I am aware in one sense this is not what Rose growers like, as it makes planting so much later, and this delays the work. Often when Roses are planted late the work is done under difficult conditions as regards weather, and at times some necessary work is overlooked. On the other hand, such seasons as this point out the great value of certain varieties of Roses for autumn flowering and massing in beds. This is worth attention, as many owners of gardens do not see their Roses at their best, and by growing late kinds there is a much longer season. There are so many good kinds to select from that it would be out of place to take up space, but as my note refers to the northern part of the country I would note the value of the Hybrid Teas for late flowering. One of our brightest beds in the garden this November was Marquis of Salisbury, the larger and beautiful Mrs. W. J. Grant, or Belle Siebrecht, and several varieties of the Polyantha section.—A. C. N.

**Pear Passe Crassane in mid-winter.**—How rarely we see a good crop of this excellent dessert Pear in gardens, even where this fruit receives special attention. This is to be regretted, as I do not know of a better mid-winter Pear than this. A few seasons ago this old variety, if I mistake not, received a first-class certificate from the Royal Horticultural Society for its excellence, the fruits exhibited being very fine, and I think were grown by Mr. Woodward. Certainly those who saw and tasted them were astonished to find how good the flavour was. It may be considered wrong to recommend any variety that crops badly, and I am aware there is great force in this argument; but why not endeavour to grow it well? I notice that the last year or two our fruits have been better, I mean

the crop is finer, and this is owing to less pruning. This variety, like several others, will not stand severe pruning: as a cordon tree I found it useless, also on a wall, unless given more freedom. Another point, I think, that causes a great difference is the stock. This variety on the Pear stock with us rarely carried a dozen fruits; it needs double grafting to prove successful, though I have heard from several growers that on the Quince stock it gave fair fruits, but the trees were not robust. It is worth a trial, as good winter Pears are scarce.—G. W. S.

**Humea elegans poisonous.**—It is now nearly forty years since the poisonous qualities of *Humea elegans* were first brought painfully home to me, as after potting some plants I was attacked by an inflammation of the eyes, which lasted for several days. I did not, however, at that time associate the pain and irritation with the *Humea*, but subsequent attacks immediately after handling the plant showed that it was undoubtedly the cause. From that time any handling of the *Humea*, however slight, has led to a recurrence of the inflammation, yet on many people it has no effect whatever. Strange to say, my eyes are particularly sound and keen, and *Primula obconica*, which troubles so many, does not cause me the least inconvenience, however much it may be handled, and such subjects as Nettles and the tropical Laportias worry me less than they do most people.—H. P.

We have received the following from "A Victim": "*Humea elegans* is poisonous, and should not be brought near the eyes. I have suffered for some weeks with an inflamed eye caused simply by drawing my hand over the leaves, and afterwards accidentally rubbing the eye. This has caused much pain, and is almost as bad as being stung by a wasp."

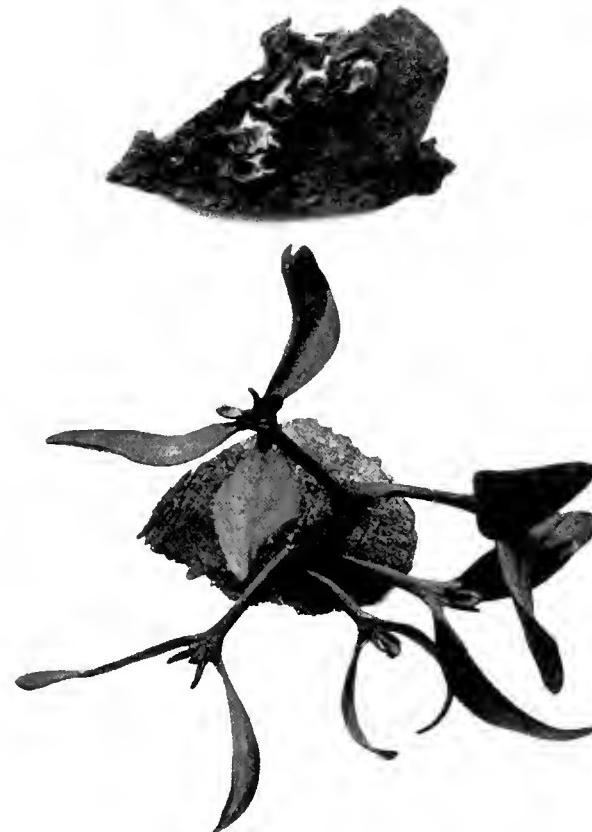

**Parrotia persica.**—This is one of the many things which at its introduction and for some little time afterwards was grown under glass. Experience, however, having shown this to be unnecessary, *Parrotia persica* has been since used in the south and west of England at least to enrich our shrubberies rather than the greenhouse. It is still a comparatively rare shrub, but may be strongly recommended to the notice of planters because of the brilliant autumn colour of its foliage. The leaves are a glowing crimson about one-third of the way down from the top, the remainder being a bright yellow with a touch of green towards the base, a peculiarity that may vary a little on different soils, but is fairly constant. It does best with a little shelter in some corner of the pleasure ground, with a screen of trees and shrubs to the north and east. Strong healthy plants are most quickly obtained from layers. This *Parrotia* is not particular as to soil, that is, so far as growth is concerned, but as noted above this has its influence on the autumn colouring of the foliage.—E. BURRELL, Clarcourt.

**Veronica speciosa.**—Well-flowered specimens of this New Zealand species or any of its many garden varieties are very useful throughout autumn and early winter, either for

sheltered corners out of doors or for grouping with other things in the greenhouse or conservatory, for the flowers are borne freely, are rich in colour, and well shown off against the deep green leaves. The type bears blue flowers in axillary racemes 3 inches long; this plant, although pretty, is by no means so beautiful as some of the garden varieties of which *Eclatante*, *Constellation*, and *La Seduisante* among the reds, and *Mme. Chrétien*, *Merveille*, and *Purple Queen* among the purples are worthy representatives. In the case of these varieties the inflorescences are 4 inches or more long, conical, and densely packed with blossoms. Unfortunately, the species is not hardy, except in a few favoured localities; it may, however, be planted out of doors, keeping a stock in a cold frame. When planted out in this way flowers are usually more freely produced, and on the approach of winter the plants may be lifted and potted and used for indoor work. When planted in a sheltered position plants occasionally pass through mild winters without harm near London, though more often they are badly damaged if not killed outright.—W. DALLIMORE.

### MISTLETOE.

In earlier days of our island the Mistletoe (which we associate with Christmas alone) was sacred to the month of March. Then this curious parasite was venerated in many countries. In Scandinavian mythology it figured largely, and was considered powerful alike for good or evil mind or body. Isaldee the beautiful was said to have been slain

MISTLETOE: GERMINATION (TOP) AND TWO YEARS' GROWTH.

by a shaft of Mistletoe. It was a sacred growth to the Druidical priesthood, who called it "all healing," especially when grown on Oak. Among the ancient Britons the cutting of the Mistletoe was a high and important function. The plant was at its best in March, and New Year's Day was then held on the 10th of that month.

The cutting of the Mistletoe was held as near that date as possible, but the moon was an important factor in the proceedings, and "the sixth night of the moon" was held as a law of the Medes and Persians for this rite. A procession was formed to the grove of Oaks where the sacred Mistletoe had been found—priests in white, men solemnly marching and leading, adorned with garlands, two white oxen.

In the brilliant moonlight the chief Druid climbed the tree, armed with a golden blade, with which he cut the branches of Mistletoe, and passed them to other priests below, who guarded it jealously, for its virtue was lost if it touched the unhallowed soil. Then the oxen were sacrificed, and the procession marched home with the sacred burden, to be used in many forms, each part of its leaf, stem, and berry having its value, and being prepared as infusion, powder, ointment, &c., to be doled out by the priestly apothecaries as a specific for all ailments. Nay, even a spray of leaf and berry, after having been submitted to various incantations, was worn by the proud recipient next the skin (on the breast) as a protection against evil spirits.

Times and seasons were supposed to add to the magic powers of the Mistletoe, which, as a medicine, is no longer valued. Its use, however, long survived the Druids, and has continued more or less until comparatively recent years. Apothecaries at one time gave large prices for it. It was supposed to be specially efficacious in epilepsy. Now it appeals to us chiefly at Christmas, and in the form of a "kissing bush," by which name the rustics know it, is a survival of the old custom of hanging it in houses as a talisman against the evil one.

Herefordshire, Worcestershire, and other Midland counties send large quantities to London for the Christmas market. A further supply comes from abroad—Brittany and elsewhere. It is a pretty sight to see a ship unloading Mistletoe in one of our northern docks, where the merchandise is usually more useful than ornamental. The name is Saxon—"Mist" glue and "Tan" twig; the berry when broken is found to contain a thick sticky matter like glue, also a single seed.

The wild Mistletoe is propagated by birds, who feed greedily on the sweet, luscious berries; the juice sticks about their bills, and they are rubbed on adjacent trees; juice and seed stick to the bark, and in certain places grow. The berries are ripe in March and April; many are left even until then. At the ends of the light twigs, where birds have no standing place, these fall to the ground and die; they cannot propagate as other seeds in the soil.

The Mistletoe is not like many parasites, such as the Brocmrape, Eyebright, and others of that genus, who feed on the roots of tree or plant, or, as certain fungi, which are nourished on dead portions of bark. As the Mistletoe is choice, and selects the best juices of the tree, as this parasite increases in size the parent tree dwindles, and in time dies. It is obvious that to the flourishing Mistletoe a full supply of sap is necessary. Even in the winter months, when the whole structure should be at rest, very graphic is the Greek derivation of parasite, meaning "one who eats at the expense of another."

It is very interesting work for the amateur gardener inoculating Mistletoe. This can be very

successfully done. The writer has found March the best time for grafting. The berries should be taken fully ripe, and choosing a young Apple, Pear, or Thorn tree, a branch of two years old growth should be selected; squeeze a berry on to the bark on the under side of a branch until it is firmly placed.

The sticky juice soon dries round the seed, and the embryo inside feeds on the juice, assisted by the sun, air, and rain for many months. Meanwhile it is throwing out tiny threads of roots into the bark, and the new layer of bark finally encloses it. In twelve months, if successful, a little green stem is visible, which soon puts forth two hardly visible leaves, and the growth may be considered fairly established. Many failures ensue, so it is wise to experiment on many parts of the same tree, and a useful ingredient is patience.

Mistletoe is rarely seen on the Oak. In a recent enquiry and search, twelve specimens only were

MR. T. ALFRED H. RIVERS OF SAWBRIDGEWORTH.

found in Herefordshire and one in Worcestershire. The latter was an object of great interest and pride. It grew, unfortunately, on the roadside, the parasite being on one of the lower branches. This in time was found to incommodate traffic; certain branches were condemned by the road authorities and cut down, and the celebrated Mistletoe Oak deserved its name no longer. Great indignation was expressed, and a year or two elapsed, when the Mistletoe appeared again on one of the upper branches—probably had been caused by sap, or fibre had run under the bark and upward.

It is said by Mistletoe growers that once in a tree, like some disease, it is impossible to eradicate. Long may this curious parasite flourish in our land, and may Christmas time still find us greeting our dear ones under "a bonny bush of the fair Mistletoe." We like to see the greyish green leaves and silvery berries apart from their associations. Their colouring is pleasing.

MARTIA.

## WORKERS AMONG THE FLOWERS AND FRUIT.

### T. ALFRED H. RIVERS.

**I**N the world of fruit growers and raisers the name of Rivers is a household word, and we feel sure a portrait of Mr. T. Alfred H. Rivers, who, with his brother, is carrying on so faithfully the traditions of the firm, will interest our readers. Fruit culture is beginning to arouse interest in the minds of amateurs, who are not unmindful of the blessings of a good orchard planted with trees, that give, through good culture, satisfactory crops of wholesome produce. THE GARDEN has not been slow in its attempts to wake up amateurs, as well as farmers and cottagers, to a sense of their loss by not giving the fruits of the earth their proper place in garden economy. We know how keen the growing of hardy fruits, Apples and Pears in particular, is becoming, by the many notes contributed to our columns of recent years, and it is through the efforts of such raisers as Mr. Rivers that our gardens are in the present age so abundantly blessed with wholesome and well-flavoured varieties. We have lately written of the splendid pot trees, the Cherry, Peach, Nectarine, and others at Sawbridgeworth, so that further reference to this matter is needless, and as Mr. Rivers recently read before the Horticultural Club a paper dealing with this subject, we hope soon to publish the remarks then made for the guidance of those who intend to make an indoor orchard on a small scale.

In looking through the list of fruits raised by the grandfather and father of the present firm, it is astonishing how many are grown in England, and we may say the gardens of the world at this day. Conference Pear, illustrated in THE GARDEN, November 22, was born at Sawbridgeworth, and is a Pear likely to take a high place in the future among dessert fruits. Its peculiarly distinct rose-tinted flesh is very juicy and rich, and the tree bears abundantly. And among Nectarines and Peaches many of the varieties we praise for their beauty and lusciousness we must thank the Messrs. Rivers, such as Nectarines Cardinal and Early Rivers'; the former is of value for forcing only, that is, it is an excellent fruit for pots, which those who have orchard houses should take note of. This we have also illustrated on more than one occasion, the brilliant colouring and exquisite flavour of the fruit warranting frequent reference to so excellent an addition to our indoor Nectarines. It ripens ten days before another variety raised by Messrs. Rivers, namely, Early Rivers', which is one of the most popular fruits of the present day. Goldoni, the famous Lord Napier, Pineapple, Rivers' Orange, and Stanwick Elrige were also raised at Sawbridgeworth.

It is interesting to glance through the collection of Peaches, where the same splendid work of the past is evident, because here we find such varieties as Duchess of Cornwall and Thomas Rivers, two of the most recent acquisitions, and among older varieties may be named Alexandra Noblesse, Crimson Galande, Dr. Hogg, Early Beatrice, Early Rivers', Gladstone, Golden Eagle, Goshawk, Lord Palmerston, Princess of Wales, Early York, Sea Eagle, and

the Nectarine Peach, a goodly list of varieties so well known that descriptions are needless.

The work of raising seedlings has been as successful among the Plums as in the case of the Peaches and Nectarines. Few who enjoy the luscious quality of Early Transparent, Golden Transparent, and Late Transparent Gage Plums know that these were raised at Sawbridgeworth, or that the famous Monarch, Stint, The Czar, Late Orange, and President may also be numbered among those that were produced through the keen interest and skill shown in hybridisation by the founders of the firm.

To walk through the houses and broad acres at Sawbridgeworth is fraught with interest, and it is gratifying to know that fruit hybridisation is carried on with the enthusiasm that filled those pioneers of the firm who have blessed mankind with products so wholesome and comforting. We need not write more of the Messrs. Rivers of Sawbridgeworth than to draw attention to the accompanying portrait of Mr. T. Alfred H. Rivers, who, with his brother, Mr. H. Somers Rivers, is carrying on the work of the past with zeal and a right appreciation of the increasing importance of the British fruit industry.

## THE FLOWER GARDEN.

### CACTUS DAHLIAS AS GARDEN FLOWERS.

**W**HEN the just advertised meeting of the National Dahlia Society is held, on the 16th inst., I purpose, as a non-exhibiting member, to see whether it may not be possible to induce the committee to show some interest in the Cactus section of Dahlias as garden flowers, and a little less for it as mere exhibition subjects. It is rather pitiful that a society calling itself "national" should seem to have no higher aims than in mere exhibitions. It may be retorted, doubtless, that so far as the Auricula, Carnation, Rose, or Chrysanthemum societies are concerned these have no other aims, and so far it is relatively true. But then, no one can grow any of the flowers named without greatly aiding their value as garden decorators, for all have been such ever since they have been cultivated. Dahlias hardly come into the same category, as the large show and fancy varieties do not make good garden plants, and the Cactus varieties generally even less so.

So, from a purely garden point of view, the Pompons and those unclassed varieties commonly called decorative, but are not Cactus varieties, are the best ones, yet these are just now outside the range of consideration, which is, what does the National Dahlia Society do to help make the Cactus forms pleasing in gardens? We are sometimes told in relation to these flowers that if you thin and disbud and otherwise manipulate the plants, you may make decorative plants of them. But we want a strain of true Cactus Dahlias that are naturally decorative, as are the Pompons and a few of the irregulars of the Dahlia tribe, needing no manipulation.

Why cannot the Dahlia Society obtain the sanction of the Royal Horticultural Society to conduct a trial of new varieties in the Chiswick Gardens and offer prizes for the best novelty, that, whilst combining true Cactus quality in the flower, with a pleasing

floral habit, should satisfy impartial judges that it was naturally an effective and even beautiful garden plant.

A. DEAN.

### GRASS LAWNS AND DAISIES.

I HAVE seldom seen a lawn, one of considerable extent—so infested with Daisies as was that at West Hall, Byfleet, recently. There were many portions of it in which Daisies materially exceeded the grass in density, and getting rid of these weeds became a problem hard to solve. But as some portions of the lawn needed raising it was resolved to lift a large portion of the turf, and when up each turf was unrolled on a table and every Daisy in that way easily extracted. That was done last winter with marked success, so that now there is not a weed to be seen on any portion of the lawn thus treated. That has emboldened the gardener to face the labour of lifting, weeding, and relaying all the other portions of the lawn, and thus, and only thus, will a complete reform in the aspect of the lawn be obtained. The process may be a little costly, but it is most efficacious, and results amply repay.

A. D.

### LAPAGERIAS OUT OF DOORS.

ALTHOUGH the Lapageria has been familiar to gardeners in this country for more than fifty years, yet many are somewhat sceptical as to its flourishing when planted out of doors. There are but two Lapagerias, L. rosea and L. rosea alba, and both have been successfully cultivated outside in North Wales. When their requirements are thoroughly understood there are but few plants easier to grow; on the other hand, if they are imperfectly understood failure is almost sure to follow. The main point to remember, as regards the growing of Lapagerias out of doors is to secure strong healthy plants. Weak plants, even if they can be induced to live, will probably give but poor results. Now as to the best position in which to plant them. The site must not be too deeply shaded, neither should it be fully exposed to the sun; therefore it must be where it may obtain the morning sun, whilst partially shaded from it in the afternoon. The second point to remember is this: Lapagerias require a shallow soil, a deep compost soon gets sodden and sour. Dig a hole about a foot deep and a foot wide, in close proximity to the selected site, and enclose the space with old slates, tiles, or anything of a similar nature. This will prevent the roots ramifying into the cold and poor

soil beyond. When the planting has been done fill in this space with a compost consisting of loam and peat in equal proportions, with sufficient sand to keep it porous, and immediately stake the plants to prevent their being bruised. In order to get an improved effect the Lapagerias should be planted alternately. Although the plants are hardy—or to be literally correct, they may be grown outside through the winter—it should not be forgotten that some protection from frosts will tend to prolong their lives, the roots especially being protected by a good mulching of manure.

JOHN DENNAN.

*The Laurels, Cains Cross, Stroud, Gloucester.*

## TREES AND SHRUBS.

### HYDRANGEAS.

**H**YDRANGEA HORTENSIA in the south of England is one of the most valuable flowering shrubs, and in Devon and Cornwall, where it is largely grown, creates noble autumnal effects. The

bushes reach a great size, single specimens sometimes being met with 6 feet in height and over 7 feet in diameter. Such a plant when covered with hundreds of massive bloom-heads, soft pink or pale blue in colour, presents a lovely picture, but it is when seen in quantity that these Hydrangeas show their value in the landscape. Succeeding under deciduous trees, they may be seen on some estates flowering on either side of a wide carriage drive at the foot of great Elms, Limes, or Oaks, whose branches meet overhead, and affording a charming vista of soft colour. In the full sunlight they flourish equally well, blossoming, perhaps, with even greater freedom. The bluest Hydrangeas that I ever saw, whose colouring was almost Forget-me-not-like in tint, were growing at the edge of a tall cliff overlooking the sea in dry soil, and absolutely unshaded from dawn till night, this instance disproving the theory advanced by some that the blue colouring is due to the plants being grown in shade. Although the normal pink hue is pretty, the clear blue is much more lovely, but the reason

A GROUPING OF HYDRANGEAS IN DEVONSHIRE.

of this abnormal colouring has yet to be determined. Some assume that this is due to the plants being grown in a soil impregnated with iron, others attribute it to the influence of peat. In a certain case, however, where numbers of Hydrangeas are grown in a soil containing a large proportion of iron, scarcely more than two or three plants show signs of blue in their flowers, and plants may be found growing in peaty soil which bear blossoms of the normal pink tint. It is often asserted that anyone can produce this blue colouring by adding iron filings to the soil in which the plants are growing, but, as far as the writer's experience goes, the flowers borne by plants so treated are of an unpleasing, muddied, purplish pink, totally unlike and immeasurably inferior to the clear colouring of the naturally blue flowers. Bushes may often be seen bearing flowers, some of which are pink, some blue, and some of an intermediate hue, but in this case the blue is rarely clear. Plants may also be met with growing but a few feet apart, one with pink flowers, the other with blue. Interesting as is this question, it has but little bearing on the merits of the Hydrangea as an outdoor plant in the warmer districts of the British Isles, and that these are exceptional, whether its flowers are pink or blue, will be admitted by all who are familiar with it in the open. Commencing to flower at the end of July or early in August it holds its blossoms

in full beauty for many weeks. Gradually their tints fade, but even as late as November great pale flower-heads may be seen, that at a little distance are still decorative. *Hydrangea stellata rosea* bears pretty flowers with pointed petals. The blossoms have the property of changing colour, being first white, then purple, and lastly becoming almost scarlet. *H. quercifolia* is another interesting species; and *H. paniculata*, the only really hardy member of the family, with its pyramidal heads of white flowers, is well known and deservedly popular. *H. scandens*, the climbing Hydrangea, is a summer flowerer, and is seen at its best when wreathing the bare trunks of great trees. Being of a self-clinging habit it ascends the trunk without any assistance, and in ten years will reach a height of 40 feet. Its flowers are not particularly showy, the inconspicuous fertile blossoms being greatly in excess of the larger sterile flowers. This, like *H. Hortensia*, is only half-hardy. S. W. FITZHERBERT.

#### STEPHANANDRA FLEXUOSA.

THIS is a delightful but little-known Japanese shrub closely allied to the Spiraeas. Although of little beauty as a flowering shrub, its elegant pale green, Fern-like foliage alone makes it worth a place in any collection of choice hardy shrubs. In the autumn this subject is particularly beautiful, as it takes on a fine tone of crimson which cannot fail to arrest attention. It seems to prove quite hardy in the Midlands, and Mr. Crump has it doing well at Madresfield. At the time of writing this note—November 21—a specimen between 2½ feet and 3 feet high, forming a compact and graceful bush, was a perfect glow of colour in the above-mentioned garden. This is a good test as regards its hardiness, as Madresfield is by no means a warm garden, owing to the heavy soil, damp situation, and the fact that it is subject to severe frosts.

ARTHUR GOODWIN.

#### WINTER PROTECTION FOR ROSES.

WHERE standard Tea Roses are not safe from winter frosts the handiest way of sheltering them is by means of coverings of straw or Bracken. Where Bracken is to be had, which is only in districts that do not willingly grow the best Roses, as it is an unfailing indication of a poor, sandy, dry soil, it is the best of coverings, as it is long and dry and warm of nature, and is less conspicuous and unsightly than straw. But in most

places straw is the material most easily obtained and applied. The illustration shows the kind of straw coverings used by Mr. Mawley, the eminent rosarian, at his garden at Rosebank in Hertfordshire. This picture speaks for itself as to its purely utilitarian object. The snowy scene, when a garden is at its most dreary time, is somewhat chilling; but this protecting material is necessary if we would save our standard Teas from destruction. This form of Rose is more delicate than the bush, and we well remember the late Mr. Girdlestone telling us that protection was essential.

### NOTES ON HARDY PLANTS

#### SOME CHOICE HARDY FLOWERS.

**O**F surprises the present year has been full, flowers which should have prospered failed, others apparently doomed to extinction bloomed their best and are in perfect health. A few desirable things which flowered well here this season are noted, in the hope that some assistance may be given those who wish to make a selection from the choice importations of recent years. The climate is cold, elevation 250 feet, gravel soil, well drained, and fairly protected from wind.

#### LILIUM NEPALENSE.

A spike of its lovely tea-green and claret flowers was before me gathered from the open border on November 1. Hitherto we had been unable to bloom it outside. Planted out it never failed to make large buds, but they were unable to develop. This cold, wet season they have done well in the same position where they previously failed.

#### EXOGONIUM PURGA.

A lovely hardy Convolvulus from Mexico, little known, but of rare beauty and a rampant climber, is now (November 22) dotted with its large purple salver-shaped bloom.

#### ECHINACEA ROSEA SPECTABILIS.

A new and remarkably fine hybrid from *Echinacea angustifolia*, which has shown its capabilities with flowers 9½ inches in diameter, broad strap petals, bright pure rose colour, perfectly formed.

#### EREMURUS

of different species and hybrids are being extensively grown, and make noble groups. We lift very early each year and get our finest blooms by so doing. I append a list of the desirable ones:—

Robustus	peach.
Elwesii	
Olga (true),	lilac.
Himrob (hybrid),	brick red.
Perry's Hybrid,	apricot.
Wallace's Hybrid,	coppery yellow.
Warei (tall)	
Bungei (short)	yellow.
Bungei praecox (short)	
Himalaicus	
Elwesii albus	white.
Olga angustifolius	

A warm, well-drained rich soil and shelter from wind favour their finest development.

#### RHODOCHITON VOLUBILE,

from Chili, is not new, but very rarely seen. No climber is more appreciated with its hundreds of nodding claret bells. Give

WAY OF PROTECTING STANDARD TEA ROSES

moisture, shade, and root protection, but it is better lifted and planted out each spring. To those who like the very best

#### DELPHINIUMS

Kelway's Persimmon leaves nothing to desire; it is a hybrid (*Grandiflora* × *Belladonna*), requires special treatment, never seeds, and should not be allowed to bloom twice. We had it with 6-inch to 7-inch spikes, with laterals to the ground, and its flowering extends over two months, truly a magnificent variety. Lemoine's

#### NEW MONTBRETTIAS

(hybrids), notably *Tragédie*, are very fine, though not with larger flowers; they are easier to grow outside than *Crocosmia imperialis*. We have them with 5-inch spikes, a vast number of flowers, finely coloured, and of great size and substance.

#### PRIMULA MEGASEFOLIA

from Persia is again flowering, but requires frame protection to look its best; it is hardy, but flowers at the wrong time. *Primula Stuartii*, both yellow and purple, a fine Himalayan species, is worth growing in shade and damp, though overrated. The finest new thing we have had in our garden this year was

#### VERATRUM CALIFORNICUM,

of which I send a photograph. The spike of pure white flowers was 8 inches in height, and remained in bloom many weeks. This species differs in habit from the others.

#### WATSONIA MERIANA ARDERNEI,

or O'Brien, a perfectly hardy albino Cape bulb of great beauty, reputed difficult to flower. So we found it until we sat down to puzzle out its peculiarities. Now we turn out gigantic corms as large as big Gladioli, and 6 inch spikes covered with white flowers. (See paper by Mr. Peter Barr, page 376, THE GARDEN, November 29, 1902).

#### LYCHNIS GRANDIFLORA

(the true Chinese species)—a beautiful re-introduction figured in Paxton's "Magazine of Botany," single, somewhat dwarf, with fimbriated salmon-coloured petals, a crimson ring, and blue centre—is very desirable, easily raised from slips, and loves damp loam.

#### CAMPANULA MIRABILIS,

though quite hardy and growing finely, florally hangs fire. Ours will be four years old next summer, and should flower well if appearance justifies the assumption. Some very fine Campanulas are being introduced. Try *C. bononiensis alba*.

#### A DOUBLE WHITE HEPATICA,

pure in colour, has flowered here this spring; a new and very choice thing from the Continent.

#### PEONIA LUTEA,

a yellow Tree Paeony from Yunnan, has come, I hope, to stay.

#### GENTIANA ACAULIS VAR. KOCHII,

a glorified Gentianella of great substance, size, and fine colour, from the Greek Mountains, is an acquisition if it continues to do well.

CAUCASIAN SCABIOUS VAR. PERFECTA, both white and blue, is a decided improvement on the original introduction.

#### HEUCHERA.

The new hybrids of these charming plants are great additions to the borders—Flambeau, La Perle, zabeliana, and others. Here on November 18 Flambeau had numerous spikes 3 feet high, loaded with large rosy bells, perfect in form and colour, and most decorative.

#### DIANTHUS KNAPPII,

a very pretty canary-yellow little Dianthus well worth growing.

#### ARCTOTIS GRANDIS.

Yes, this has come with a great flourish of trumpets. I lifted mine and potted them a month since. Next year I shall leave them in the borders, where they will make large bushes in one season and are nice, but not worth much trouble, as they close with the least cloud and early in the day. I grow

#### GERBERA JAMESONI

to perfection inside a cool house: outside it exists. Can anyone grow it *finely* outside in this climate? If so, how?

#### VINCA ACUTILoba,

a lovely large white Periwinkle, blooming in autumn here. On December 1 it was covered with flowers.

P. H. MULES.

*The Old Parsonage,  
Gresford.*

#### TUNICA SAXI-FRAGA.

THERE is always a danger that in our desire to obtain new flowers we may neglect some of the older plants, whose beauty it may be is such as to entitle them to increased admiration rather than to want of appreciation. Many of these older flowers are left unnoticed, while others with possibly much less beauty and of more difficult culture are written about and sought after. This is often the case with alpines, and among the flowers of which one hears comparatively little is *Tunica Saxifraga*, a small alpine plant which has much in the way of beauty to recommend it, and which is so comparatively simple in its requirements that almost anyone with a rockery can cultivate it. Even in a rather dry border it can also be grown with success when it has a position near the front, so that it will not be overgrown by other flowers and overlooked by the observer. It does not appear to be at all particular as to whether

it has much sun or not, as it is flowering here quite as well in a greatly, though not completely, shaded position as in one in full sun. *Tunica Saxifraga* has quite a modest beauty, and the greatest stretch of imagination will not give it any but this quiet grace, which is, indeed, the charm of many alpine flowers. It has very narrow leaves and slender stems, forming a little tuft of rather prostrate branches a few inches long and only rising 3 inches or so above the ground level. The flowers, like those of some of the *Gypsophilas*, are in little panicles, but are produced in succession so as to maintain the bloom for a long time. As this note is written (November 17) it is still in flower, although having been in bloom for several months. It comes into flower in early summer. The blooms are rose or white in colour. *Tunica Saxifraga* apparently

prefers a sandy soil, and looks its best when trailing over a small ledge in the rockery, where its elegant foliage shows well against the stones. I always look upon it as a plant which prefers lime, though that is not absolutely essential to its well-being. It is easily raised from seeds, and by this means can be readily established on walls or even on roofs.

S. ARNOTT.  
*Cursethorn, by Dumfries, N.B.*

#### RUDBECKIA LACINIATA FLORE-PLENO

THIS Rudbeckia, with its double flowers, is no longer a new or rare plant, for it has already been cultivated for five or six years, yet it is a splendid perennial, to which we should like to draw

A NEW VERATRUM V. CALIFORNICUM.

attention on account of its exceptional decorative merits. Robust and vigorous, it is more than two metres high, and flowers freely from July to October. The flowers are perfectly double, and resemble in shape those of a small decorative Dahlia; they are of a beautiful bright yellow. A much better flower-bearer than the perennial Sunflowers, the plant has the very appreciable advantage over them of not sending out suckers, and of being able to remain in one place for a long time without transplanting or requiring any other attention except careful staking. Although the flowers are double this Rudbeckia produces some seeds, which may be used for propagating, but breaking up strong tufts in autumn or in spring will easily furnish a sufficient quantity of plants which, placed at once in the situation required, will bloom the second year. The best situation for

Rudbeckia laciniata is in scattered groups in the middle of borders, by the side of the paths, but it may also be grown as a single specimen or in groups upon lawns. The flowers which, in spite of their duplication, are not unwieldy, are from their extreme abundance and bright colour a splendid help to house decoration.

S. MOTTER, in *Le Jardin*.

#### ECHINACEA PURPUREA AND ITS VARIETIES.

ECHINACEA PURPUREA (Moench, synonymous with Rudbeckia purpurea, L.) comes from Louisiana, and has been known since 1790. It is not, therefore, a new plant; it is rather one that has been almost entirely forgotten, yet it excited great interest when it made its reappearance in 1900 at the Paris Exhibition, where MM. Cayeux and Le Clerc, seed merchants, exhibited it. It was much admired, and redeemed this beautiful perennial plant from oblivion. The following is its description:—The stem, which is stiff, smooth, and slightly branched, attains a height of from 1 metre to 1·20 metres. It is furnished with rough, slightly indented leaves; the radical leaves are oval-lanceolate in shape; the caudine leaves are narrower and thinner. From August to October these stems produce heads of a dull reddish purple, with blossoms of from 5 centimetres to 10 centimetres in length. They are very beautiful, and produce as much effect when growing upon the plant as when they are cut. At the same time, by their shade of colour, which is rare amongst the flowers of this genus, they bring a new element and diversion of colour which will be much appreciated by decorators.

From seeds, MM. Cayeux and Le Clerc have obtained several interesting forms of this plant, showing variations in the colour and in the disposition of the tongue-shaped petals of the flowers, &c.; in a word, these varieties are a sensible improvement on the type. Before the quite distinct results obtained by MM. Cavenx and Le Clerc, the two following forms of this Echinacea were already known: E. p. intermedia, with flowers wider spread, rounder, and fuller than in the ordinary type; E. p. serotina, a form with bristles and narrow petals. Among the new varieties which have been obtained, we will especially mention the two following: E. p. rosea elegans, a robust and very floriferous plant, with flowers of a beautiful clear pink; E. p. atropurpurea, with flowers of a deep purple-red. We believe that by hybridisation and selection other varieties will be obtained.

Like all the Rudbeckias, this plant, in order to grow well, requires a substantial, deep and wholesome soil, and a situation not too much exposed to the sun. It can be used for flower-beds or for shrubbery borders, or it may be placed by itself in groups upon the lawn, or banished to the kitchen garden, there to provide flowers for cutting; in a word, it is in its place almost everywhere. As a cut flower, it is also very valuable. This plant can be propagated either by dividing the clumps or by sowing the seeds. The division of the clumps should be made in autumn, or preferably in spring.

If it is preferred to propagate by sowing, the seed should be sown in May (in heat, if the plants are to flower the same year), or preferably in June, under a cold frame. The seedlings should be planted out in a nursery bed, and placed in their final situations in autumn or in spring. This

plant is naturally variable, and in the self-sown seedlings many different colours are found, varying from pink to purple.

JULES RUDOLPH, in *Revue Horticole*.

## THE ROSE GARDEN.

### ROSE ALTAICA.

ONE of the most interesting matters connected with a knowledge of plants is the tracing of a species and its near developments through many lands widely distant from each other. In this pretty species, one of the earliest Roses

CLIMBING AIMEE VIBERT\* (A WHITE ROSE) RAMBLING OVER WILLOWS.

to bloom in English gardens, we have almost a counterpart of our native Burnet Rose (*R. spinosissima*). Indeed, it might easily be taken for the same species, and doubtless is only a geographical variation with some distinctive character, imperceptible to the ordinary observer, that botanists consider of sufficient importance to give it a separate specific status. For garden purposes it is a Burnet Rose, flowering a little earlier than our well-known one, with leaves a shade paler and yellower, flowers a little larger, and manner of growth rather more vigorous. Its special value in our gardens is that coming into flower some ten days or a fortnight before the Burnet Rose, it extends the all too short blooming season of our Briars.

### CLIMBING ROSES.

#### BEST TWENTY-FOUR VARIETIES.

THE rich selection now available of the very vigorous Tea-Scented, Hybrid Tea, and Noisette Roses renders it an arduous task to name the best twenty-four. Something must depend upon the aspect and the district to guide one in making a selection. Those varieties marked with an asterisk would do well in the southern counties, on south, east, or west walls, but they should be avoided where the conditions are not so favourable.

Theo, too, one must thoroughly prepare the ground for the plants, not forgetting that, as the Roses are permanently planted, due provision should be made as to their future requirements. A rich, well-drained soil encourages vigorous growth, and the plants need careful watching in summer to prevent the border getting very dry. Frequent surface applications probably do more harm than good, but a good soaking now and then of weak liquid manure will work wonders.

Many make a great mistake in their treatment of climbing Roses the first season. They often leave the growths their entire length as purchased. I believe in cutting them back hard the first season, the result being some vigorous new growth which will form an excellent foundation for future success.

The best twenty-four are as follows: Billiard and Barré, Bouquet d'Or, Celine Forestier, Climbing Aimée Vibert, Climbing Captain Christy, \*Climbing Kaiserin Augusta Victoria, Climbing Belle Siebrecht, \*Climbing Nipheta (a warm wall indispensable), Dr. Rouges, Duchesse d'Auerstadt, Gloire de Dijon, \*Henriette de Beauveau, Kaiserin Friedrich, \*Lamarque, Longworth Rambler, Mme. Alfred Carrière, Mme. Jules Siegfried, \*Maréchal Niel, M. Desir, Noella Nabonnand, Pink Rover, Rêve d'Or, Souvenir de Mme. Joseph Metral, and Wm. Allen Richardson. The latter, the best orange-coloured Rose, should be planted against a west wall. P.

### THE PENZANCE BRIARS.

THERE appears to be a very considerable difference in the constitution of the Penzance Briar Roses, which when rightly used are such valuable things in the garden. While several seem to retain their vigour for a considerable number of years, there are others which become weakly, scraggy, and useless in a comparatively short time. This is, unfortunately, the case with those which approach most nearly the Austrian Briar in their colouring. Lady

Penzance, one of the prettiest and most pleasing and distinct, is one of these, while Lord Penzance is another, though I think the first is the one which lasts for a briefer time in good condition. I have observed this in a number of gardens, and have heard frequent complaints about the short time they remain in health. On the other hand, there are several which look as if they would remain in health and vigour for a number of years. Of these, such as Anne of Geierstein and Meg Merrilies seem among the most reliable. I should be glad to learn how far this has been observed by others, and also the best remedies for this failing. Pegging down would probably keep up a supply of young plants without raising cuttings or budding on other Briars, but this is unsuitable for those who grow these lovely Briars as hedges, for which they are admirably suited.

S. ARNOTT.

## AN ARTIST'S NOTE-BOOK.

## ROSA SINICA ANEMONE.

**F**OR rosarians apparently there are many surprises in store if hybridists will devote more attention to certain desirable species hitherto untried.

Prior to the introduction of the

hybrid Rose illustrated,

*R. sinica* was regarded as a very undesirable species for all save those who were fortunate enough to dwell in the southern counties, for besides not being thoroughly hardy this Rose could not be induced to blossom.

I only know of one hybrid of *R. sinica*, except the one under notice, and that is *R. fortuneana*, which is no great acquisition. But when *R. indica* was employed as the pollen parent the beautiful flower that we now illustrate was obtained. We appear to have not only a hardy Rose, but also a free bloomer. No single Rose of recent years has captivated lovers of this class more than *R. sinica* Anemone; its huge silvery rose-pink blossoms and glistening foliage make it a very general favourite. It is a very interesting plant when grown in a pot, and being then shielded from untoward weather its beautiful flowers are more lasting.

It should not be beyond the power of hybridists to give us a fine large-flowered golden-yellow single Rose by crossing *R. sinica* with a deep yellow Tea. A single yellow Rose of this description would be a grand acquisition. P.

## RIVIERA NOTES.

DECEMBER brings with it a number of hardy flowers which contrast with the summer ones that linger on here until the cold nights of January give them their quietus.

*Iris alata*, *I. stylosa*, and *I. Palæstina*, with its rather dull white flowers, make a change that is welcome after the gaudy splendour of *Salvia splendens*; but the rich purple winter-blooming form of *Iris germanica*, with the light sprays of the violet-calyxed *Salvia Ionantha*, and the many spikes of tall-flowering Yuccas are even more welcome. *Senecio arboreus* is a fine tree-like shrub that deserves more extended

cultivation; its shining Chestnut-like leaves and immense corymbs of yellow flowers are indispensable at this time of year, and as it enjoys a little shade it is all the more welcome near trees or Palms that make a background to its broad masses of foliage and flowers. A big shrub of such beauty should also be grown under glass in

England wherever there is room for it, as it is fairly happy under pot culture.

*Illicium anisatum*, the Star Anise of commerce, is another first-class shrub now in flower. It is so rarely seen, and its beauty is so exceptional when fully developed, that I can only imagine that its straggling growth as a young plant has discouraged new gardeners. Its light clusters of starry-white flowers, its red stems, and bright green Laurel-like leaves

now, and I heard a gardening friend that had newly arrived say they were worth coming all the way from England to see; but their beauty is ended in a week or two.

The same fate will befall the gorgeous Poinsettia and Lasiandra bushes, so splendid on the sheltered and sunny side of a group of Palms which accentuate their occidental magnificence. The first chill of winter will soon mar their beauty, so that they are not plants for every garden, even on these sheltered shores; still it is worth while to try them where the soil is not too cold or the position too low and damp. Of dwarf shrubs it is difficult to find a more charming trio than the Golden Flax (*Linum trigynum*), which for the next six weeks smothers itself in flowers when in shade and shelter. In the open it is liable to sunstroke or a stray frosty night, but as a covering to the ground in the shrubbery or under Palms it is quite at home. In company with it, the tall old-fashioned *Ageratum mexicanum* and the dainty sprays of the rosy *Lopezia miniata*, that enjoy a little more sun, make a combination that is very satisfying and not too common.

There are happily many silver-leaved plants and variegated shrubs in beauty now, but there is a great want of a good white-flowered dwarf shrub, *Eupatorium weinmannianum* and white Paris Daisies only raise the wish there were something still better. If then the new *Hoheria populnea*, figured the other day in THE GARDEN, proves a good winter bloomer it will be most welcome. In England we welcome the red Holly berries as a relief to the white snow; here we need a good white flowering shrub as a foil to the immense quantity of winter-flowering Salvias and Cupheas, which are all shades of colour save white.

Of sweet-scented shrubs, I think that *Buddleia salicifolia* carries off the palm just now, though the masses of Heliotrope are very abundant still. The early and large-flowered *Chimonanthus fragrans* is just opening. On a very dry bank, the rose, clover-like heads of *Grevillea Preissii* remind one how far less beautiful the commoner *G. thelemanniana* is; the abnormal-looking *Senecio pinifolia* carpets the ground underneath it, a very quaint combination, and one that lasts for many weeks.

EDWARD H. WOODALL.

## RECENT PLANT PORTRAITS.

THE Botanical Magazine for November contains portraits of the following plants:

*Crinum natans*, native of Guinea.—This is a variety with pure white flowers, which is closely allied to *C. purpurascens*; it is amphibious, and is usually found in gently flowing fresh water streams.

ROSA SINICA ANEMONE  
(SLIGHTLY REDUCED).

are all very ornamental, and for some years I have seen one old specimen flowering abundantly throughout the whole winter. It is very hardy, will prosper in the darkest, dampest corner, and in that extraordinary frost of two years ago never even "turned a hair," as the saying is. *Dahlia imperialis* and the tall *Salvia fruticosa* are at their best just

The bulbs sent to Kew flowered in a tropical tank in September 1900.

*Cymbidium simonsianum*, native of Sikkim and Assam.—This is not a very ornamental variety, and came to Kew as *C. dayanum*. It flowered in a cool house and is sweet scented.

*Catasetum quadrifidens*, native country unknown, only the male plant is known; it is chiefly of botanical interest, and does not possess much beauty.

*Lavatera acerifolia*, native of the Canary Islands. This is also known as *L. phenicea* and *Saviniona acerifolia*.—This is an extremely pretty shrub, closely resembling *L. Assurgenteflora*, and requiring the protection of a greenhouse in winter. From the Cambridge Botanic Gardens.

*Bauhinia acuminata*, native of tropical Asia, also known as *B. candida*.—This species has pure white flowers of good size; it has been for many years an inmate of the Palm house at Kew, but never flowered till October of last year.

The December number of the same publication contains portraits of

*Iris Giolisi*, native of Kurdistan.—In point of size of flower this is as far as is at present known the monarch of the Iris family; it belongs to the Oncocyclus section of the family, and is very well represented on a fine double plate. It flowered in the open border near a south wall at Kew in June, 1902.

*Aristotelia racemosa*, native of New Zealand, also known as *Friesia racemosa*, *Triphalia rubicunda*, and *Makomako incolarum* or *Wineberry colonorum*.—This is rather a pretty dioecious

flowering shrub, requiring the protection of the temperate house at Kew, but hardy in the Isle of Wight and in many parts of Ireland; it has also a conspicuous red underleaf on the mature foliage, which is not shown on the plate.

*Cirrhopetalum Hookeri*, native of the Western Himalaya.—This is a somewhat curious little dull yellow-flowered Orchid of merely botanical interest.

*Crowea angustifolia*, native of West Australia. It is also known under the synonym of *Eriostemon Torezanninovii*.—This is a very pretty greenhouse shrub with numerous small rose-coloured flowers. The family is well known in our greenhouses through *C. Saligna*.

*Kalanchoe Kirkii*, native of Nyassaland, also known as *K. coccinea* var. *subsessilis*.—This is rather a pretty free-blooming variety, bearing large bunches of small flowers which have yellow centres and pink tips to their petals.

W. E. GUMBLETON.

## BOOKS.

### Trees and Shrubs for English Gardens.

**Trees and Shrubs for English Gardens.**—This is one of the most important contributions to the now famous *Country Life* Library, and treats of a subject which the author says "has never been so fully treated and illustrated as it deserves." We may make another quotation from the preface, and express the same wish and hope of the author, that "the book may do something to make English gardens more beautiful and interesting, and that it may lead many to see the better ways of planting, also that it may be the means of bringing forward the many trees and shrubs of rare charm that are generally unknown or unheeded. The word 'English,' of course, stands for the British Isles."

It cannot be urged against this excellent work, so pictorially treated and beautifully got up, that it is not comprehensive. There are thirty-nine chapters, apart from no less than 125 pages of tables, in which are described the most beautiful of flowering trees and shrubs, arranged alphabetically, and with descriptions as clear and readable as possible without lessening their practical value. There are 130 illustrations, which have their own teaching value, and are reproduced with exceptional clearness, and the whole book is thoroughly well printed, as those who are acquainted with this library will well believe.

The opening chapter concerns the want of variety existing among trees and shrubs

in the average garden. As is well said, "Even the landscape gardeners, the men who have the making of gardens, with, of course, notable exceptions, do not seem to know the rich storehouse to draw from, and a list of beautiful kinds that are not planted so largely as they should be is given with brief descriptions. It will be well, perhaps, to give the titles of the chapters. They are as follows:—Want of Variety a Blemish, Ornamental Planting in Woodland, Grouping of Trees and Shrubs, Healthy Paths in Outer Garden Spaces, Trees and Shrubs in Poor Soils, Pruning of Flowering Trees and Shrubs, Propagation of Hardy Trees and Shrubs, A Winter Garden of Trees and Shrubs, Autumn Colours, Trees and Shrubs with Fine Fruits, Weeping Trees and their Uses, The Use of Variegated Trees and Shrubs, Trees and Shrubs for Sea Coast, Trees and Shrubs for Wind-swept Gardens, Conifers (including Pines) in Ornamental Planting, Care of Old Trees, Trees and Shrubs for Waterside, Trees and Shrubs for Rock Garden, Removal of Large Trees and Shrubs, Young Trees and Sunstroke, Shade Trees for Streets, Trees and Shrubs in Scotland, Tender Trees and Shrubs in the South-West, Tender Wall Plants in the South-West, Hardy Bamboos, The Heaths, Native and other Hardy Evergreens, Shrubs for Small and Town Gardens, Shrubs and Flower Borders, Shrubs under Trees, Hardy Shrubs in the Greenhouse, Shrub Groups for Summer and Winter Effect, the Use of Hardy Climbing Shrubs, Flowering and other Hedges, Pleached or Green Alleys, the Garden Orchard, the Worthy Use of Roses, and Planting and Staking Trees. This list shows the thoroughly general character of the book, and the tables will be found full of useful information. Many of the chapters concern phases of tree and shrub culture rarely touched upon either in books or journals, and that describing the best ways of pruning will, it is hoped, be found of the greatest use to those who are quite at a loss as to the proper treatment of the many families of flowering trees and shrubs available for British gardens. The following is a description taken at random of *Pyrus floribunda* and given in the tables (page 405):—"Country, Japan; colour and season, rose, late spring and early summer. A delightful tree, and, happily, much planted in gardens. It is quite small, little more than a graceful bush, rarely exceeding a height of 10 feet, wreathed in flowers in the proper season, the buds intense crimson, but opening out a paler shade, and thus there is a gradation from one colour to another. It should be freely grouped and planted in small and large gardens. The fruits are yellow, and about the size of a Pea. There are two good varieties, *Atrosanguinea*, which has flowers of much deeper colour than those of the type, and *flore-pleno*, or *Malus Parkmanni*, as it is more often called. This has semi-double red flowers and reddish wood and leaves," or this from the chapter upon

### "A WINTER GARDEN OF TREES AND SHRUBS."

"The things that are and the things that are to be. Let us take this thought as company and try to glean some of Nature's own lessons of fitness. How instinctively we seek, for a winter ramble, the shelter of the woodland copse, which is not far distant from any English country habitation. The broad grass drive is boar with frosty rime in the shadow of the bushes and crisp under foot. Under the trees the ground on either side is carpeted with Ivy. The lithe, trailing stems, wreathed with their shining, taper-fingered leaves, so exquisitely pencilled, are cushioned on the soft, feathery Moss, or twine in or out amongst the Hazel stocks, or creep at will up the nearest tree trunk. One can scarcely look at Ivy on a winter's day without a thrill of admiration, especially this woodland sort, for, mark it well, Nature never encourages the coarse-leaved Ivy of common cultivation within her domains. How perfect in its grace is this fine-leaved Ivy, how utterly content with its surroundings, how resolutely cheerful, be the circumstances of weather or situation what they may!"

\* "Trees and Shrubs for English Gardens." By E. T. Cook, Editor of THE GARDEN. Published at *Country Life* Office, 20, Tavistock Street, Covent Garden, London; and by George Newnes, Strand.

SPIREA CANESCENS (SYN. S. FLAGELLIFORMIS).  
(From "Trees and Shrubs for English Gardens".)

Clinging lowly to the ground, or mounting to the topmost branch of some tall Pine, it is equally at home, and why should we not agree with that good-natured naturalist Charles Waterton in his assertion that forest tree was never injured by its clasping stems? An English plant for our English climate, it may be used to make beautiful an unsightly building, to clothe a decaying tree stump, as bush or border or mantle, in a hundred different ways, yet it is never out of character, and never touches a jarring note.

"Then those tall Hollies, see how dauntlessly they stand up above the undergrowth of Hazel. How living and warm, in their ruddy glow, are the clustering berries in the glint of the fearless leaves. For expedient sake, their lower branches have been trimmed away, and greatly we gain by it, for otherwise that lovely contrast of their ashen-grey stems would be hidden from our eyes, but over yonder a fine old Holly tree stands alone, which axe and knife have left untouched, and how graceful is the curved sweep of its feathering boughs. No foreign evergreen can excel it for symmetry of form or winter garniture of leaf and fruit. Life is astir, too, in the brown twigs of the Hazel bushes. The infant year is not more than a week or two old, yet already the tasseled catkins are swinging in the lightest rustle of the sighing wind, and begin to lift up their tiers of small woolly cowls to set free the yellow pollen dust. And so we may go on our way, and, at every turn, some rugged Yew, or clump of red-stemmed Scotch Fir, or tapering Spruce with hanging russet cones, will stay our steps, and if we look and listen they will tell us in their own way the story of their perfect fitness for our homely English landscape. Or, if we chance to be in one of the chalky districts of the South Downs we may come upon Box, the ever young, as it was called of yore, or Juniper, in its bloom of silver-grey, as precious as any, to add to the tale of our best native evergreens . . . ."

Seekers after knowledge concerning trees and shrubs will find a storehouse of information in this volume. It is a work that should be in every horticultural library.—T. R.

**Snowdrops.**\*—In this pretty little book, whose cover recalls the colouring of the Snowdrop's leaf, Miss Jackson tells, perhaps, all that there is to be said about this well-loved winter flower; about its life and growth, its beauty, its haunts and native places, its effect on the minds of poets, and the message that it bears us. The number of quotations from writers of prose and poem show, if any proof were needed, how good a place the Snowdrop holds in our estimation as a nation, and, while there is no need to sing its praises to those who care for their gardens, or have only so much as a window-box, yet they will probably find some fact or reflection, as yet unknown to them, within the two pale green covers.

#### FIVE DAYS (SEPTEMBER) IN THE TULBAGH VALLEY.

##### THE GARDEN OF CAPE COLONY FOR BULBOUS PLANTS.

THE Tulbagh Valley is remarkable for its fertility. The farmers are largely interested in the cultivation of the Vine for wine making and dop (brandy). The valley is enclosed on three sides by mountains, and is about ten miles across and about the same in length, opening into an extensive country to the north. The soil is a good sandy loam, and capable of growing all kinds of crops. The farmers are all well to do. Of late years the phylloxera has done great damage to

WYCH ELMS BY HEDGEROW. (From "Trees and Shrubs for English Gardens.")

the Vines, and the crops have been light in consequence. There is a talk of adding Tobacco to their culture. At present the farmers grow their own Tobacco, and cure it in the following way: When ready to cut the whole plant is tied up in bundles and hung in sheds till quite dry. Then the leaves are stripped off, wetted, and laid in boxes, and when it heats removed and spread out thinly on the floor to cool, then replaced in the boxes till it again heats, when it is spread out, and this process goes on till all fermentation ceases. When it is made up in rolls for daily use I tasted this home-made Tobacco and found it very strong and full of nicotine. To those in England who have a fancy for Tobacco growing this information of how the Boer manages may be useful. On my return journey to Cape Town an English Cape farmer of Wellington joined me in the carriage. Very soon his pipe and Tobacco pouch were in evidence. I picked up the latter and found a very nice cut indeed, and on tasting it remarked about its extreme mildness. He replied, "I smoke this from morning to night without the slightest injurious effect; no dry throat in the morning or bad taste in the mouth." "If," added the farmer, "I smoke a pipeful of English or American Tobacco my tongue suffers badly." On further enquiry I found that this Tobacco was sold at 3s. per lb. under the name Rising Sun, and is grown and manufactured at Hertzog, Cape Colony. This may be useful information to those devoted to the weed, and the more especially as South Africa may be looked upon as one of the great Tobacco-growing countries of the world in the future. I may add that when smokers get over the prejudice to South African Tobacco they smoke no other.

##### IN QUEST OF BULBOUS FLOWERS.

I must apologise for writing about Tobacco in a paper on bulbous plants. In company with the Master of the Supreme Court, Cape Town, I went on an expedition to Tulbagh to find Lachenalia aurea, and failed, but we found other Lachenalias and many interesting bulbs in flower, and others which would flower later on. At Winter Hock, upon the farm of Mr. Low Smith, the Green Ixia grows in profusion. He permits collectors of bulbs on certain portions of his mountain slopes, but there is one part none are allowed to trespass upon, as here the finest form is found. This he keeps sacred

to himself and friends. Unfortunately, we were rather early, so could not judge on the differences existing amongst this unique species. On the Winter Hock Farm I saw many interesting species of bulbous plants, but the day was closing in upon us so our stay was short, as one more visit had to be paid before we left the valley, and we had a long ride before reaching our hotel. On reaching my excellent friend's house the master chided me for not keeping my promise to spend some days with him. I did feel a bit ashamed, and said, "If you will come to the hotel in the morning I will spend a few days with you as soon as I see my friend off to Cape Town." True to promise Mr. le Roux came for me, and we returned to his La Rhone Farm, where I remained three days in the bosom of a charming Boer family, and found the girls accomplished musicians, quite musical, consisting of ten children, the eldest son being at college. Opposite the farmhouse stood a venerable Oak, 215 years old, which as a sapling had been carried on horseback a great distance, I think from French Hock, the early settlement of the French Huguenots. The tree is historical, and the family are proud of it and of their pure Huguenot blood. To see the large family gathered together with the kindly faces of father and mother, and the patriarch (the grandfather) at the head of the table asking a blessing on the food, and returning thanks at the close of the meal, brought to my recollection Burns' "Cottar's Saturday Night."

The younger boys were much interested in my work, and one or other accompanied me in my rambles on the flat ground. I was anxious to see what grew on the mountain slopes, and Mr. le Roux drove me as far as was possible, and we searched about, but found little that was novel; no doubt it was a little too early. The bulbous plants I found most abundant on the flat ground, growing in the moist, sandy, stony loam. The yellow Ornithogalum was very plentiful, and I could not resist the temptation to collect a quantity. It was growing in masses, and made a beautiful picture; the bulbs were rarely more than 1 inch deep, measuring from the base of the bulb, which is small, and, strange to say, the strongest plants had the smallest bulbs. In height I saw none more than 6 inches high. I am told it can attain a height of 12 inches, but in all the spots where I found it none exceeded the height named. Close by, but rarely amongst the yellow species,

grew one about 1 foot high. *O. aurea* ranges from primrose-yellow to the deepest orange, but the palest colours are the least common. I would recommend *O. aurea* to be grown in pots of from six to twelve bulbs, and even in pans of twenty-five to fifty for effect. It is seldom seen in our greenhouses, and I feel sure, if well shown at the Royal Horticultural Society, it could not fail to become a favourite. In my rambles I came upon

#### A GOOD WHITE LACHENALIA,

some bulbs of which I collected, and other species of Lachenalias, such as *L. orchoides*, *L. purpureo-cerulea*, and *L. anquinea*, but not in any quantity, so did not collect any. *L. orchoides* is interesting to collectors, but can never be a favourite. I suggest the following to those willing to take up the family, and feel sure they will not be disappointed with them, say, six in a 5-inch pot, and handled as Mr. Martin has recommended in a former number of THE GARDEN: *Lachenalia aurea*, *L. contaminata*, *L. glauca*, *L. Orthopetala*, *L. pendula*, *L. pallida* (very fragrant), *L. pustulata*, *L. purpureo-cerulea*, *L. reflexa*, *L. rubida* (very early), *L. tricolor*, *L. uniflora*, *L. liliiflora*, *L. racemosa*, and *L. rosea* (a beauty). There are others, but not having seen them I pass them over. *Oxalis* in every shade of colour, *Romulea* in many shades, tuberous-rooted *Pelargoniums* in many species (one I saw with flowers as large as the prizéd *Pelargoniums* of our greenhouse), Terrestrial Orchids abundant, *Sparaxis* ranging in colour from snow-white to the richest colours, all varieties of *S. grandiflora*. The scarlet *Ixia* was abundant. This species I do not remember having ever seen in cultivation, and I fancy it is peculiar to Tulbagh. I regret not having collected some bulbs. *Morea Pavonia* in all shades from white to deep purple, always with the dark blotch on each petal; other species of *Morea* were abundant everywhere; *Satyrions* in yellow, red, brown, pink, salmon, and striped pink and white; *Homeria elegans* abundant; *Gladiolus alatus* in great patches very striking with its brick-red flowers, sparkling as if coated with gold dust, lower petals green-yellow tipped brick-red; *Babianas* in all shades from blue to rich crimson-scarlet: the Fly-catcher in patches, the large purple-flowered variety in the distance looked like Poppies, the leaves sparkling with dewdrops: *Wachendorfias*, yellow and brown varieties, some of them 3 feet to 4 feet high: blue *Aristea*, *Haemanthus* everywhere, with their pair of large flat leaves resting on the ground, while another largish leaved plant with four leaves on the ground, I suppose a *Brunsvigia* (these two latter were not showing their flower-scapes); *Ixiias*, large-flowered species, ranging from white to yellow; *Watsonia rosea*, large breaks near the water, and the brown and scarlet forms of *W. marianna* in great masses; *Albuca minor*, *Hypoxis* from yellow to the large white species *H. stellata* and *elegans*, with its black ring at bottom of petals shading off to olive-green; *Aponogetons*, wherever there were pools of water; *Gazanias*, very abundant; *Mesembryanthemums*, large yellow, white, purple, and rose-flowered species, with thick fleshy leaves, and a smaller species in the same way, but more compact in growth. The shrubby *Mesembryanthemums* were just opening, so I missed the wonderful range of colour in this great South Africa genera.

I was much pleased to see Kniphofia in its native habitat, that is, in marsh ground; the leaves and growth were abundant, but not so effective a plant as in our gardens. I was disappointed at its sparse flowering. Had the flower spikes been as abundant as in our garden the sight from the immense quantity of plants would have made a grand effect with, say, a few thousand Red-hot Pokers. To the foregoing I will name a few additional species I saw at Tulbagh, and not being quite sure of their names submitted them to Mr. Chalwing of the Municipal Gardens, Cape Town, to name: *Geissorhiza obtusata*, *hirta* and *bracteata*, *Sparaxis bulbifera*, *Baeometra columellaris*, *Lachenalia Anquinea*, *Melanthium* sp., *Morea edulis*, *Babiana villosa*, *Albuca* sp., *Pelargonium* sp. (the large-flowered one referred to above), *Bulbinella caudata* and *triquetra*, *Hispanantha falcata*, *Bobartia gladiata*, *Hexaglotis longifolia*. In addition to the above-named bulbs there

are flowering plants innumerable. As for the bulbs put the pick in the ground anywhere and up they come; no doubt successors in flowering to the ones at the time in bloom. The flower-heads of *Kniphofia* were short and stumpy, but from the leaves should say the species was *K. Uvaria*.

A botanist working the western flora of Cape Colony should pass over the ground several times during the flowering season. Thus, Cape Peninsula, Table Mountain, Lion's Head, Lion's Rump, Signal Hill, and extend his visits to Hout Bay, leaving the Peninsula, Stellingbosch, Paarl, amongst the late Mr. Rhodes' farms, Wellington, Tulbagh, Ceres, and Worcester; and if a good walker, with staff in hand and knapsack on back, timing himself to hit a farmhouse for sleeping quarters he could make a unique collection of Cape flowers, and I do not suppose at any farm he would be refused hospitality. The Boers are a hospitable race. On all the mountain ranges of the Western section of Cape Colony *Disa grandiflora* may be found in abundance along the sides of mountain streams, and *Nerines* on the ledges of the rocks. Amongst *N. sarniensis* an occasional snow-white albino is found, and besides this many shades, from the dark scarlet to almost white. The growth takes place when the winter rains prevail. The hot summer sun dries up the leaves, and then follows the flower. The bulbs grow in crowded masses with next to no soil about the roots.

Mr. Bellantyne, at Baron Schröder's, in his handling of *Nerine Fothergilli* hits off as near as may be the conditions under which *Nerines* are found in Cape Colony. It is curious that *N. Fothergilli* is unknown in Cape Colony. Can any of your correspondents explain this? Surely some record of its first coming into cultivation can be found. Mr. Arderne, The Hill, Claremont, has three bulbs of the snow-white *Nerine sarniensis*. On one occasion he explained to me how he secured them.

PETER BAKER, V.M.H.  
Cape Town, South Africa.

### PEAS IN 1902.

[To the EDITOR OF "THE GARDEN."]

**S**IR.—The article on this subject in THE GARDEN, page 385, was most interesting to those who grow vegetables and need the best varieties, and the remarks made were to the point. A large grower like Mr. J. D. Pearson hits hard when he says many gardeners will order nearly every Pea one has in the catalogue. Now, I should have thought that gardeners knew better nowadays with so many advisers, and certainly they ought not to be called gardeners who do this; still it is refreshing to get these facts so straight from Mr. Pearson. My difficulty is that I often restrict too much, and find that at times a certain variety must still have preference, but here again this fully coincides with Mr. Pearson's remark that some Peas will succeed on land where others fail. I may go farther and assert that kinds which do well in a good loamy or moist soil fail in a thin gravelly one. In the Midland counties I used to rely chiefly on Veitch's Perfection. This was in a good deep soil, and I never saw finer crops, whereas here at Syon in a thin soil on gravel this variety fails. I have only one more remark to make, and that is, all gardeners do not study vegetable culture. Some rely upon catalogues for advice, and where so many varieties are given it is difficult to pick out the best.

I thoroughly agree with the remarks as to sowing and giving more space, not only between but in the rows. The seeds often touch, but this is a mistake; and another point is that there must be good cultivation. The Sweet Pea has made much progress of late years, because it has had more attention, more space, and more food. Give the culinary Pea the same chances and an equal

return is obtained. I do not notice that Mr. Pearson touches this latter point—that is, more space for the seed; but it is equally important, and when any doubt exists as to the seedlings being vigorous it is an easy matter to thin the plants when they are large enough. For years, in my notes on Peas, I have pointed out that the small round-seeded white Peas are not worth sowing; indeed, I go farther than Mr. Pearson, who says unless it be for autumn sowing, and even then I would sow the early wrinkled varieties in preference. We now have many fine types of early Peas, such as the Daisy type, that there is no room for the small white-seeded forms. I am glad the writer gave us the list he did. So far our best early wrinkled Pea is *Harbinger*. It has few equals as regards crop, and it may be sown in the autumn with perfect success in well-drained soils. For years I have discarded American Wonder, and it is strange that seedsmen retain it in their catalogues, as there are so many better ones. I do not send this note to condemn any one variety, but to point out the merits of those that are good. My opinion of the Laxton two—that is, *Gradus* and *Thomas Laxton*—is similar to Mr. Pearson's; they are grand, and I have grown *Gradus* in well-drained soil as a first early with every success. There is no need to grow poor varieties now, and the dwarf mid-season varieties are splendid for crop and quality, and, again, how good the forms are of the later or the *Ne Plus Ultra* section that have been selected. Some of the newer varieties, such as *May Queen*, *Early Giant*, and *Prizewinner* are splendid introductions. Again in the mid-season, we have some very fine kinds, and of the late varieties, such as *Late Queen*, *Continuity*, and the well-known *Autocrat* and *Michaelmas Pea* are of great value.

G. WYTHES.

## PERGOLAS AND THEIR BEAUTY IN ENGLISH GARDENS.

[To the EDITOR OF "THE GARDEN."]

SIR.—Of late years the appreciation of pergolas as ornamental and useful features of English gardens has greatly increased, much to the benefit of the appearance of the grounds, in the opinion of those who are well qualified to pronounce judgment in such matters, where these structures are artistically designed, clothed with flowering climbers, and placed with due regard to their fitness for the position they occupy. There naturally occur instances where pergolas are out of place, but bad arrangement is noticeable every whit as much in beds and borders as in the sites chosen for pergolas, and it would be as reasonable to banish borders and beds altogether, because in certain cases they offend the eye as to decry pergolas *en bloc* because the position of some is ill-considered. There are pergolas which apparently have been dropped casually out of the sky, so little reason is there for their location, leading from nowhere to nowhere. Such a structure is an eyesore, but if, previous to erection, its situation is carefully considered by the trained artistic eye its effect will not fail to add to the attractions of the garden. Grounds differ so greatly in their individuality that it is impossible to lay down any hard and fast rule as to the most suitable positions for pergolas, but if the site be well chosen any fair-sized garden will gain and not lose by the presence of a tastefully constructed one. In examining the profitability of pergolas, however, their value in artistic garden design must not alone be considered, but also their usefulness. Miss Jekyll in her admirable article on "The Pergola in English Gardens," which first appeared in the Journal of the Royal Horticultural Society, and was afterwards reprinted in these pages, speaks of its utility in providing shade so often grateful in summer heat. That the value of shade was fully recognised by our forefathers we have evidence in the pleached alley, which, in the old days, none of the best gardens lacked. These pleached alleys were merely passages enveloped in foliage, not permitting those glimpses of the surrounding garden that may be obtained between

the uprights of the pergola, and being also inferior in beauty owing to the exclusion of flowering subjects from their covering. However, they provided what was then deemed requisite—a shaded walk. Now, although it will be freely allowed that shade is not so needful under the too often grey skies of England as in the sunnier south, all summers are not like the past, and there are seasons when day after day the sun, whose rays may be uncomfortably powerful even in the British Isles, shines fiercely down from the unclouded heavens, and when I firmly believe shade is welcomed by the great majority of the dwellers on our shores. That there are, however, exceptions I gather from an article (page 360) appearing above the initials "E. K. R." in which the following sentence occurs: "The pergola . . . is an artificial structure which has no meaning or utility in a British garden." In the colder northern counties and on the bleak east coast the value of a pergola may be less appreciated than in warmer localities, though I must confess that there have been sunny days in Scotland and in Suffolk when I should have been thankful for shade, but the sentence I have quoted refers evidently to the whole of England, and is not put forward as a mere expression of individual opinion but as a fact admitting no denial.

If a statement be only made with sufficient assumption of authority there are those who will accept it as gospel, and it is quite possible that one who chanced to come upon "E. K. R.'s" sweeping assertion of November 22, without having read Miss Jekyll's article on the utility, rightful construction, and furnishing of the pergola in the two preceding numbers might conclude that these structures were a mistake. Unfortunately, at the present time your correspondent has the weather on his side. In December days, when ulster collars are turned up to the ears, and, despite heaped-up coal, the room is chilly, it is no time to talk of pergolas. The very name makes one shiver. But on a sultry August afternoon, when the sun beats down relentlessly from a cloudless sky and wavering exhalations flicker upward from the parched earth, it is another matter, and I venture to opine that the adherents to "E. K. R.'s" dogma would then be few and far between. Uselessness, moreover, is not the only fault that the writer alluded to has to find with pergolas. According to him they are disfigurements to gardens, for we read: "In ninety-nine cases out of a hundred the

pergola gives a 'tea garden' aspect to grounds. You suspect . . . a white-napkined waiter round the corner." Here, again, the law is laid down as by one having authority. There is apparently no question of the possibility of any other view. Pergolas are useless and disfigurements, for what can be a greater disfigurement to a garden, which the spirit of restful loveliness should invest, than a structure suggestive of a hurrying *garçon*. Naturally, I feel somewhat diffident in dissenting, however feebly, from statements advanced as uncontested facts, but, remembering the many who have advocated pergolas in these columns, writers of repute with no axe to grind—I entirely acquit "E. K. R." of the possession of this tool—but actuated merely by the wish to aid amateurs and others in the beautifying of their gardens, and remembering also the numerous charming examples I have myself seen and the attractive pictured representations of others that have from time to time appeared in THE GARDEN, I cannot permit these strictures to pass unchallenged.

I am of the opinion, with which I hope and believe most readers will coincide, that well-designed and tastefully planted pergolas add much to the charm of our gardens, and also that in hot summers they become useful as well, because of the shade they afford. The complaint is made that pergolas are artificial. Naturally, they are artificial, but surely this is no objection to them, since it is by their artificial aid that we are enabled to grow flowering climbers that otherwise would have no opportunity of displaying their beauty.

If pergolas, trellises, arches, pillars, and such-like artificial erections were swept away climbers would be necessarily banished entirely from some gardens, and in all they would be greatly diminished. I yield to none in my admiration of a Rose garlanding the head of a tree with a very cascade of swaying, blossom-laden shoots, but if we refuse to grow any climbers except on trees we shall be the losers of much beauty, for in the garden proper such opportunities are by no means frequent, whatever they may be in the wild garden. Artificial structures soon lose their appearance of artificiality under the veil of flower and foliage that hides the supporting wood or metal from sight and then cannot offend even the most fastidious eye. S. W. FITZHERBERT.

[We think "E. K. R." had in mind the wretched rustic affairs that do suggest a tea garden, other-

wise he would not have condemned the many beautiful pergolas in English gardens, grateful retreats from hot sun and the home of climbing plants of many kinds. Pergolas well placed and well made add much to the beauty of a garden, but the reverse when used without meaning and constructed without any knowledge of the way such structures should be built. The articles by Miss Jekyll recently published in THE GARDEN are an expression of our views of the importance of the pergola in English gardens, and those who contemplate making a pergola should carefully read what is there written.—Ed.]

## THE FRUIT GARDEN.

### THE FAMOUS HAMPTON COURT VINE.

OF remarkable old vines in this country that at Hampton Court is perhaps the most famous, and is an excellent example of the longevity of the vine even under artificial conditions. Even now this vine, although considerably over a hundred years old, annually bears more or less heavy crops of Grapes of excellent quality. The variety is Black Hamburg. A few years ago the border was renovated, and with the greatest benefit to the old vine; the constant training in of young wood also has greatly assisted to maintain its fruitfulness. T.

### THE APRICOT UNDER GLASS.

It is only on a limited scale that the Apricot has hitherto been grown under glass in this country for dessert, the reason being, I suppose, that for this purpose it has not been sought after so much as the Peach and the Nectarine, and also for the reason that the tree is not so amenable to treatment under glass as most of our other hardy fruits, and especially so when grown in pots as an orchard house tree. Fair success may be obtained by this method of cultivating the Apricot, but it is necessary to observe great care, especially at the time the trees are in bloom, when a free circulation of air is absolutely necessary to a good set of fruit, and high inside temperature

must be guarded against. A glass-covered wall or a house is usually employed when given over to the growth of this rich and delicious fruit, as when grown in this manner the quality, size, and flavour of the fruit are immensely improved. One characteristic of the fruit must be taken note of before it can be successfully grown under glass, and that is that it is most impatient of the least semblance of forcing in the early stages of its growth, and those contemplating its culture under glass must bear this in mind if success is to be attained. The late Mr. Ewing, Bodorgan, Anglesea, used to devote one of his then famous glass walls to their culture, and succeeded very well; but not at first, when the attempt was made on the glass walls without fire-heat, on account of the amount of condensed moisture in the house, which, at the time of the year when the trees were in bloom in the moist climate of Anglesea, could not be removed, and, consequently, the bloom did not set well. However, this difficulty was removed on the introduction of a flow and return hot-water pipe, which, however, was never used except when the trees were in bloom, and that in conjunction with as much air as could be admitted when dry enough. Good crops were afterwards secured, although from my experience of the Apricot it does not bear so freely under glass as it does out

THE FAMOUS OLD VINE AT HAMPTON COURT. (*Planted about 140 years ago.*)

of doors. The best examples of this system of culture used to be found at Welbeck Abbey, the seat of His Grace the Duke of Portland, where a large extent of glass-covered walls was devoted to their culture. The important points necessary to bear in mind in the successful cultivation of this fruit under glass are to keep the house fairly cool at all times and not to use fire-heat, except when the trees are in bloom, and then only in conjunction with as much air as can be safely given, remembering that the atmosphere of the house, at least for a few hours in the day, should be dry, when the bloom should be fertilised by being gently brushed over with a camel-hair pencil or a rabbit's tail. When a crop of fruit is set and the final thinning is over, the crop may be hastened by closing the house in the afternoon, but not too early, syringing, of course, before closing. In this way, by utilising sun-heat, ripe fruit can be had three weeks or a month before it is ripe out of doors. The quality and flavour of this fruit are so much improved when grown under glass that a house or two devoted to its culture should be included in every good garden.

The following varieties are the best known and most reliable:—

*Frogmore Early.*—Of the early varieties this is the most reliable and best for its season.

*New Large Early.*—Richly flavoured and sweet. Improvement on the Old Large.

*Gross Pêche.*—Of large size and delicious flavour, one of the best for dessert.

*Oulton's Early.*—One of the earliest and sweetest; a great bearer.

*Shipley's, or Blenheim.*—This is a very desirable variety, being of good size, early, and one of the hardiest. One of the best for planting in the colder counties.

*Moor Park.*—The best known and most generally grown of all. It is of large size, splendid flavour, and comes in midway between the early and late varieties.

*Henskirk*—One of the most hardy and vigorous, well suited for the most northern counties. It is earlier than Moor Park. The fruit is very handsome, flesh tender, with a rich and delicious flavour.

*Powell's Late.*—As one of the latest varieties, too much cannot be said of this grand sort. It is the most hardy and free bearing and free growing Apricot we have. The fruit is large, highly coloured, and of rich and sweet flavour.

*Large Red*—This is another excellent late variety of fine colour and size, as its name indicates.

*Beaupré*—This is perhaps the latest of all, and is of the Moor Park breed. Very useful for extending the season for dessert and for exhibition purposes.

*Roman*—Of large size, good grower, flavour slightly and pleasantly sub-acid. One of the best for preserving.

*Turkey*—Smaller than the above. It is very prolific, not unlike the Roman in flavour, and is much sought after for preserving.

*Breda*—A small hardy variety, suitable for growing as bushes, pyramids, or standards in the open quarters of the garden. A. P. H.

#### HARDY FRUITS IN SEASON.

##### PEAR HUYSE'S PRINCE CONSORT.

This Pear is seldom seen at exhibitions or named in notes about Pears, possibly because its appearance is somewhat uninviting, and its flavour in some cases cannot be good, i.e., if it deserves the condemnation it received in the report of the committee of the National Pear conference held at Chiswick in October, 1885, viz., that of being "watery and worthless." Certainly, when at its best its flavour cannot quite compare with that of a good Doyenné du Comice, Thompson's, or Marie Louise, but then few can. With us, however, grown upon a south-east wall, in heavy soil, and worked upon the Quince stock its flavour is decidedly good; indeed, better than that of many varieties usually classed as first-rate, while its flesh is melting and of delicate texture.

It is not likely to impress judges who make appearance a leading point, owing to its greenish colour, which is freely speckled and slightly bronzed on the exposed side of the fruit. It is large, long, pyriform in shape, resembling in a measure General Todtlenben, and its season is the end of October and beginning of November. The tree in our case is not robust in habit, but forms spurs freely, and is a very early, constant, and heavy bearer, its young wood producing fruit buds even to the detriment of the satisfactory extension of its branches. We have not grown it as a bush or pyramid, but probably it would succeed in this way, at any rate in warm districts, and its habit indicates that it would make a good cordon.

##### PEAR MARIE LOUISE UPON NORTH WALLS.

THE season of such an excellent Pear as Marie Louise cannot be too much prolonged. It can—as is well-known and generally practised—be considerably extended by gathering the fruit, even that from a single tree at various intervals, as also by growing trees of it under varied conditions. The north wall, however, is not so often utilised for this purpose as it might beneficially be, at least in southern and western districts. Here Marie Louise does well under such circumstances, but it cannot be said that the fruits attain so large a size as do those that are produced upon more favourable sites, although its flavour is excellent, and it is clean and very russety. At the present date (November 22) we have gathered the last fruits, when the season of those grown under more favourable conditions are almost over. Trees planted against north walls are later in flowering than are those that are placed in warmer aspects, and this fact, together with that of the blossoms being shaded from early sunshine, are advantageous in so far as frost is concerned.

Monmouth. T. COOMBER.

#### GARDENING OF THE WEEK.

#### THE FRUIT GARDEN.

##### EARLY CHERRY HOUSE.

**W**HETHER the trees for providing ripe fruit early in May are planted in borders or placed in pots, they should—if it has not been already done—be cleansed in a similar manner as has been advised for Peaches, and be given atmospheric conditions suitable to their necessary slow progress. Commence forcing, if the term may be used, by closing the house at night, and ventilating it freely by day in mild weather, employing artificial warmth only where it is necessary to do so in order to maintain a temperature of about 40°. When the influence of the sun affects the temperature, admit air when it reaches 50°, and permit it with freely increased ventilation to reach 70°, gradually decreasing the ventilation, as the temperature declines, until it falls to 55°, then close the house for the day. These conditions will cause safe progress, and should not be exceeded until the buds begin to swell freely. Avoid a free use of the syringe, but promote a moderate degree of atmospheric moisture by damping the floors, &c. of the house, and the trees also in favourable weather, early enough in the day for them to become dry before night. Keep the borders or soil in the pots, as the case may be, moist; at the same time guard against excessive wet, which would discourage root action.

##### PEACHES AND NECTARINES IN POTS.

Where trees of this description are employed for producing an early supply of fruit—and under good management they answer admirably for this purpose, and afford, provided the varieties are suitably selected, a lengthened succession of fruit—they should now receive attention. If they were as they should have been, top-dressed, pruned, and cleansed in early autumn, their roots will have already taken possession of the fresh compost used for top-dressing, and they may be at once placed

indoors without further attention to these matters. Until the buds begin to move, exercise patience by keeping a night temperature of about 45°, that for the day being 5° higher; at the same time make judicious use of the syringe, but regulating its employment in agreement with external conditions, and at all times permit the buds to get dry before nightfall. Keep the ventilators more or less opened continually in mild weather, but allow the temperature to reach 65° from sun-heat. Little artificial warmth will be necessary during the early stages of development.

##### CUCUMBERS.

Climatic conditions during winter are unfavourable to the well-doing of Cucumbers, and necessitate very careful management to ensure sufficient vigour in the plants to enable them to yield even a moderately regular supply of fruit. The bottom heat should be regularly kept at about 80°, and the atmospheric night temperature at from 60° to 70°, in agreement with the state of the weather, with a day rise of about 5° by artificial means, and a corresponding rise from sun-heat.

T. COOMBER.

*The Hendre Gardens, Monmouth.*

#### INDOOR GARDEN.

##### TREE CARNATIONS.

THESE subjects form one of the choicest of flowers we have for cutting at this dull season of the year. They will now be flowering freely, and every encouragement should be given them to lengthen the period of blossoming, and assistance given to bring out the quality of bloom. Liquid manure and soot water may be applied in a weak state occasionally; but in no case should a gross soft growth be encouraged. Sufficient fire-heat should be applied to maintain a night temperature of 50° to 55°, the last-named in mild weather, with a corresponding rise of 7° to 10° during the day. Afford plenty of air so as to prevent the condensation of moisture, as the Carnation cannot bear a close atmosphere. Only in frosty or foggy weather need the ventilators be kept closed.

##### VIOLETS.

in frames will need plenty of air given them in mild weather to prevent damping or undue excitement of the plants. Keep the frames close in foggy weather, but the sashes may be entirely removed during sunshine. Attention must be given to cleaning and lightly stirring the soil, and if watering is necessary it should be done with a small spout water-can in order to keep the leaves dry. Cleanliness of the glass, for the full admission of light, is a more important detail in the winter management of Violets than is generally thought.

##### CINERARIAS.

Admit abundance of air while the weather remains mild, and choose the early part of the day for watering. Do not allow the plants to become dry at the root, and give frequent applications of manure water to plants showing their buds until the flowers show colour, and it should then be discontinued. Rain-water is preferable, as hard water will retard free growth. Plants growing in lean-to houses should be turned regularly to prevent them growing one-sided. Fire-heat should only be applied to keep out frost. Keep a sharp look out for aphids, to the attacks of which Cinerarias are especially liable.

##### CAMELLIAS.

Great care must be taken with the watering of these plants, for the giving of either too much or too little will cause the buds to drop off. Weak liquid manure made from sheep dung and soot will be of great advantage to plants that are confined in pots and tubs. If large flowers are required, then each shoot should be allowed to carry but one bud. In other cases, two buds may be left. Thoroughly sponge and cleanse the foliage and stems, using warm water and soft soap.

JOHN FLEMING.

*Wexham Park Gardens, Slough.*

## THE ROCK GARDEN.

### THE ROCK GARDEN IN NOVEMBER

ROCK GARDENS in November cannot be expected to be full of bright flowers, especially as cold winds, sharp frosts, and heavy rains have held their sway and worked sad havoc among our favourites. In many instances, however, bright flowers—though they may be scarce—are not entirely over.

*Helleborus maximus* has opened into bloom this month, and is flowering abundantly. The bright scarlet

*Schizostylis coccinea* is still holding its own here in the west, and even the still brighter scarlet of *Lobelia cardinalis* may be seen here and there. That handsome rock shrub

*Convolvulus Cucumeroides* is still showy with its blush-

have at this time of the year bright hues of foliage. These would be quite as attractive in a rock as in the wall garden. To these I will now add a few others which are more specially adapted to adorn the rock garden in winter.

*Gaultheria procumbens*, which does so well in a half shady or boggy place, is now at its best, being studded with numerous bright scarlet berries and dark bronzed foliage.

*Pernettya mucronata* is a rock shrub of a bolder type, but most suitable to form the background. It loves peat, and, as a rule, its large berries are produced most abundantly, and are a great attraction through winter. Red or purple are the prevailing shades of the berries, but since numerous hybrids have been raised plants with berries of blush white, dark red, and crimson contribute quite a variety of colour, and there is certainly something very neat about these Myrtle-leaved plants clustered with berries in various shades of colour.

*Eruca sativa* must also be mentioned as an attractive plant during November. Not merely on account of its flowers—indeed, these have

passed long ago—but on account of the beautiful bright scarlet with which its leaves are margined and blotched. As the plant is naturally of a semi-prostrate habit, these pendent shoots in their autumn tints are quite a picture where they have a chance of falling over bold crags of rock.

*Euphorbia Myrsinifolia* is another plant which, though not in bloom, is handsome just now. Its leaves do not assume an autumn tint streaked with scarlet or other colours, but they are exquisite in themselves on account of their peculiar shape and their beautiful glaucous colour.

*Herniaria glabra* as a carpeting plant is very striking in summer, but in winter its bright green carpet closely covering the ground, and scarcely half an inch high, is doubly welcome. There is a brightness and freshness about it which appeals to the eye, and presently when Winter Aconites, Snowdrops, and Chionodoxas begin to pierce its surface it will be more attractive still.

*Ajuga reptans variegata* we admire in spring for its dark blue flower-spikes : but now it is, perhaps, still more striking. Not only does the variegated foliage form a striking contrast to the withered appearance of plants generally, but this foliage has the additional charm of being margined or blotched with scarlet and purple; some of the leaves have turned purplish bronze altogether, and form a contrast to other leaves which as yet show the white and green variation.

*Encrusted Saxifrages* of all kinds, too, are now very attractive, from that queen of Saxifrages, *S. longifolia*, with its huge rosettes of silvery grey, down to the minute *S. vernalis*. The silver-grey of their foliage looks brighter now than during summer, when their modest colouring was eclipsed by hundreds of other flowers of brighter hues.

*Arum italicum* is one of the most striking objects just now. Its large leaves have not died down, but show their beautiful network of white or creamy yellow veins more distinctly than ever. This does best in a half-shady nook where it can have moisture.

*Festuca paniculata* is never grown for the sake of its flower at all, but for its evergreen foliage. Just now it deserves more than usual attention, for its glaucous leaves, scarcely more than 6 inches high, stand out in bold relief against foliage of a dark or scarlet tint.

#### WORK IN THE ROCK GARDEN DURING DECEMBER.

Work in the rock garden during this month should mostly consist in giving some of the mountain gems we treasure the protection they may require during winter. In the northern counties plants like *Androsace lanuginosa*, *A. sarmentosa*, *A. chumbiensis*, and many others require the protection of a piece of glass fastened in such a way as to allow the plants to have plenty of light and air, but to protect them against excessive rain. Other tender plants like the beautiful *Gerbera Jamesoni* might, if severe frost is anticipated, be all the better for a covering with a few branches of Spruce or Silver Fir laid over them in the manner of roofing tiles, i.e., to carry off excessive moisture without altogether stopping ventilation. Fortunate are the owners of gardens which require no protection whatever, for protecting materials are unsightly. Even the glass mentioned in the case of choice *Androsaces* may be as a rule dispensed with if the plants are not on level ground, but planted sideways, so that excessive moisture could not accumulate in the centre of the rosettes of leaves and cause decay. Of equal importance is the rule not to allow the rosettes of such plants to rest on the damp soil, but on porous stones, which would absorb the extra moisture.

Elmside, Exeter.

F. W. MEYER.

## APPLE CORONATION.

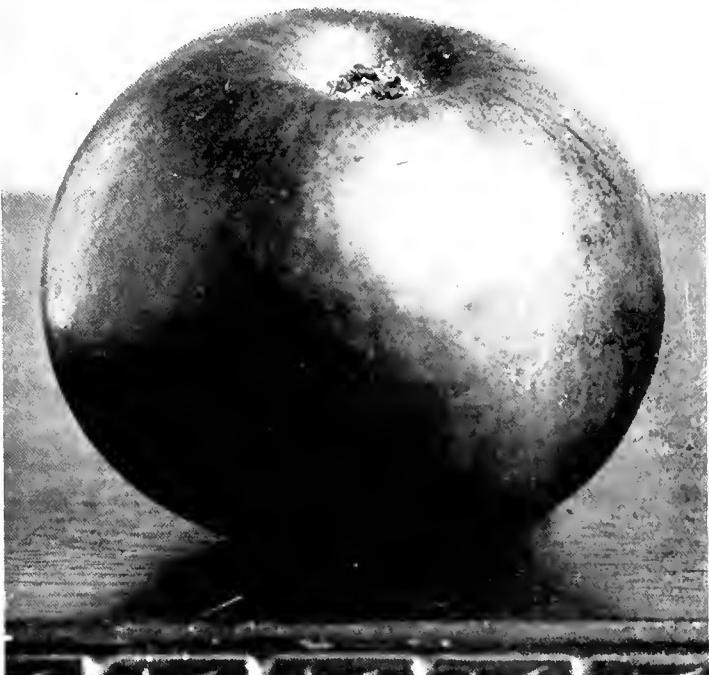

This is a welcome addition to the list of first-rate dessert Apples, and well merited the distinction of an award of merit made by the fruit committee of the Royal Horticultural Society on October 21 last. The tree is of compact habit and of medium growth ; the fruit is fairly large, and may be described as flattish round. At first the skin is green, changing as the fruit matures to a pale yellow on the shaded side, while that exposed to the sun becomes mottled and streaked with red as the fruit ripens ; eye open, and set rather deeply in a round depression : stalk straight and very slender, measuring three-quarters of an inch to an inch in length ; this is set in a smooth, rather deep cavity. For table use from November to Christmas there should be a good future for this new Apple. It is of first-rate quality and an excellent flavour that reminds one of Cox's Orange Pippin, and is probably accounted for by reason of the fact that this variety was one of the parents. Apple Coronation was raised at Buxted, and was exhibited by Mr. H. C. Prinsep, of Buxted Park Gardens. The entire stock has been acquired by Mr. G. Pyne, Denver Nurseries, Topsham, Devon, who is sending it out under the name mentioned above.

## NATIONAL DAHLIA SOCIETY.

### A FEW HINTS.

This society, which is devoted to the Dahlia, as the name suggests, is about to hold its annual meeting. We presume this is an occasion when future work is discussed and suggestions welcomed. May we, therefore, hope that something may be done towards encouraging flowers of the older decorative sorts, with wide flat petals, as we wrote in THE GARDEN, October 4, page 225 :—

"It is just these wide-petaled Dahlias that are of all their kind the ones most useful in good gardening for grand effects of colour in the late summer and autumn. It is not to be denied that the starry flowers have a prettiness and refinement of form that will befit them for

APPLE CORONATION.

white flowers in spite of the weather, and the same may be said of hardy

*Fuchsias*, which in Devon and Cornwall are blooming abundantly.

*Senecio pulcher* seems determined to die hard. At Exeter its bright purple flowers are still expanded, and more buds are to open. Of

*Campanulas*, the only one blooming here is *Campanula portenschlagiana major*. Another plant which just now is quite attractive is

*Othonna cheirifolia*. It has opened several of its yellow blossoms quite recently, and its handsome glaucous foliage forms a fine background to the flowers.

Though the flowers just mentioned are the only ones which have come under my notice, others may still be flowering in other parts, but with the exception, perhaps, of Christmas Roses, they are only the lingering remnant of beauty passed away, and the chief effects of colour in the rock garden during winter must depend on ornamental foliage or berries. In my notes on wall gardening in November I mentioned several Sedums, Saxifrages, Arenaria, Plumbago Lappentæ, and others which

the show table and for room decoration, but to let these be the only garden Dahlias that we may now have seems to us a sheer perversion of good taste and good sense. Beautiful though some of the most free blooming of them are, there is scarcely one among them that for honest and simple garden use can approach in value such of the older flat-petaled kinds as, among the reds, King of the Cactus, Cochineal, Lady Ardilann, and Fire King; among yellows, William Pearce, Lady Penzance, and Lady Primrose; or such fine things as Henry Patrick among whites. To let this grand type of a good flower fall into disuse is to neglect some of the very best flowers we can have in our gardens.

"We cannot but think that this exclusive approval of the starry, twisted-petaled flowers among the garden Dahlias is but a passing fashion, and would earnestly counsel growers not to lose sight of the fine old kinds such as those just named. Some of the most thoughtful and practical amateurs would not on any account be without them, and, though admitting and admiring many of the starry kinds, would never allow these to claim precedence of their more useful brethren."

The Dahlia Society can do something to encourage flowers of the highest value in the garden without detriment to the merely competitive displays, in which we fear the value of the kinds there shown for the garden is never considered. Societies, in spite of the deeper interest taken in garden flowers, are too conservative, and those are wise who wake up to a sense of their shortcomings and get out of a narrow groove which will ultimately mean disaster. If a society devoted to one special flower will think a little less of the show ground and more of the garden it will win more sympathy, and therefore more supporters than the organisation wedded to the rules and routine of fifty years ago.

## MISCELLANEOUS.

### CORDON APPLE TREES.

**H**AVING read a letter signed "J. M." in your issue of the 22nd ult., I require the exact opposite to your correspondent, and shall be grateful if you would kindly give a list of the very finest flavoured Apples both for eating and cooking, combined with free bearing. I want to plant espaliers round my kitchen garden.

[The following are good growers and will succeed well as espaliers. They are arranged as nearly as possible in the order of ripening. They should be obtained grafted on the English Paradise stock.]

Dessert: July and August.—Juneating, Mr. Gladstone, Irish Peach, and Devonshire Quarrenden. September and October.—Kerry Pippin, Worcester Pearmain, Williams' Favourite, and James Grieve. November and December.—Cox's Orange Pippin, King of the Pippins, Mother, and Allington Pippin. January and February.—Cox's Orange Pippin, Adams' Pearmain, Scarlet Nonpareil, Blenheim Orange, and Beauty of Kent. February to May.—Christmas Pearmain, Hubbard's Pearmain, Lord Burleigh, Duke of Devonshire, Rosemary Russet, Sturmer Pippin, and Allen's Everlasting.

Cooking: August and September.—Lord Suffield, Duchess of Oldenburgh, Lord Grosvenor, and Keswick Codlin. October and November.—Ecklinville, Grenadier, Stone's, Seaton House, Blenheim Orange, Lord Derby, Bismarck, and Bow Hill Pippin. December and January.—King of Tomkin's County, Lane's Prince Albert, and Royal Late Cooking. February to May.—Alfriston,

Newton Wonder, Northern Greening, Sandringham, Belle de l'ontoise, and Annie Elizabeth.—Ed.]

### INJURIOUS INSECTS AND DISEASES AFFECTING FRUIT TREES.

(Continued from page 368.)

#### THE VINE.

PROBABLY of all the fruits under hot-house culture the Vine is subject to far more diseases than any other. The most troublesome is that known as shanking, the next worst being mildew.

Shanking generally makes its appearance just when the berries begin to change colour, and is continued with more or less activity until the crop is ripe. It is first detected by the formation of a slender black thread round the berries, healthy growth is arrested, the stalks lose their vitality, and the berries become shrivelled and very sour. The primary cause of shanking will be found in the stoppage of a proper flow of healthy sap. This may be caused by a soil overcharged with organic matter, which condition, combined with bad drainage, causes acidity of the soil; the Vine will then develop luxuriance rather than maturity and ripeness of wood. It may be that the foliage has been destroyed by red spider, invited by too dry an atmosphere and too high a temperature. A never-failing remedy for shanking is to raise the roots and relay them in new compost composed of good virgin turf-loam.

*Mildew* (*Peroospora viticola*).—This fungus causes two forms of disease. If the leaf is attacked the disease is called downy mildew; if the fruit, it is known as brown rot. Leaves affected by this fungus show upon their upper surface spots of a greenish yellow colour, while on the under side of the leaf opposite these spots may be seen a peculiar downy or frosty growth. These spots may be quite small and few in number or very abundant, the frosty growth almost covering the lower surface. When the fungus is abundant the leaf soon yields to the disease, turns brown, and falls from the Vine. In severe cases the disease extends to the young branches. The attack upon the fruit is generally early, causing many of the berries to cease growing, turn brown, and fall off. In treating Grapes for this disease, Bordeaux mixture may be used with good effect. Early washing of the Vines is of advantage in freeing them from spores which may have found lodgment in the crevices of the bark.

*Powdery Mildew* (*Ineimula spiralis*).—This disease usually makes its appearance about the middle of summer. It attacks the leaves, young shoots, and fruits, covering them with a powdery growth. It differs from the downy mildew in covering the upper surface of the leaves with white patches of various size and shape. Sometimes it spreads quite early over the surface and resembles a delicate spider's web. It does not send filaments into the tissues of the host plant, but taps the epidermal cells with numerous minute suckers, and through these saps the adjoining cells, while all the filaments are spread over the surface of the leaf. The fruit when attacked shows upon the surface a whitish dust. This rapidly increases in abundance, and soon the berries shrivel and their skin cracks, admitting other spores of decay, which complete the destruction of the fruit. Being confined to the surface, this disease yields to the application of almost any fungicide, but flowers of sulphur is probably the best.

#### INSECT PESTS.

*Red spider* (*Tetranychus telarius*).—With the exception of the phylloxera, red spider is the most general and troublesome pest of the Vine. It is not a true spider, but belongs to what are called spinning mites. It has a difficulty in moving on perfectly smooth surfaces, but by means of its claws and the pin-headed bristles with which they are furnished, it moves readily on the under side of the leaves, and fastens its threads to the hairs or slight prominences, thus gradually forming a coating of web, amongst which it lays its eggs, and under this shelter a colony increases with alarming rapidity, especially if the

house is kept hot, dry, and badly ventilated. The colour is various, depending on the nature of the food; possibly, also, in some degree on the age of the individual. The attacked leaves may be known by their greyish marbled appearance above, whilst beneath they are whitish and slimy from the covering of the web. The red spider is most injurious to Vines in hot dry weather, consequently washing and syringings, which will render the leafage and ground moist, will be serviceable. The extreme dryness of the air and soil are thus counteracted and a healthy growth encouraged, which more or less counterbalances the injury to the leaves from the suction of the mites. It is important to check the attack at the very beginning, and for this purpose syringings morning and evening are advised, sent hard at the under side of the leaves so as to break the webs and wash them down with the contained mites. Sulphur and soft soap combined in various ways are amongst the most reliable remedies.

*Thrips* (*Thrips minutissima*).—This insect is of a dark brown colour or almost black. It feeds upon the leaves of the Vine, thereby interfering with the proper elaboration of sap, and being a dirty insect it soon spoils the fruit. Like the red spider it flourishes best in a dry atmosphere. If taken in time sponging with kerosine emulsion will be found a thoroughly effective remedy.

*Mealy Bug* (*Dactylopius odonidum*).—This pest is one of the most troublesome met with in Vine culture. When once introduced it spreads from the branches to the shoots, and thence to the fruit. A good remedy is to apply a coating of methylated spirits with a soft brush. Fir tree oil and paraffin in a diluted form also causes death to the pests.

*The Vine Louse* (*Phylloxera vastatrix*).—Of all the insects with which the Grape grower has to contend this is the most terrible, and no certain remedy for its destruction has yet been discovered beyond that of taking out all the Vines and burning them, together with the soil in which they grow, thoroughly cleansing, painting, and lime-washing the houses, then replanting with fresh Vines.

*Heela Villa*, Harpenden.

J. J. WILLIS.

## OBITUARY.

### E. BROWN.

**I**T is with feelings of much regret that many of our readers will hear of the death of Mr. E. Brown, jun., the popular and much esteemed vice-chairman of the Southampton Royal Horticultural Society, and eldest son of Mr. E. Brown, J.P., of Above Bar and Hill Lane, Southampton. His death took place quite suddenly at his residence on Thursday morning, November 27. Mr. Brown's fame as a most enthusiastic and successful Chrysanthemum grower and exhibitor is known beyond his local society, he having exhibited at the shows of the National Chrysanthemum Society and others for several years past. He was undoubtedly an example of a *bona fide* amateur, who did the whole of the work connected with his hobby with his own hands, from striking the cuttings, through all the various stages until ready for exhibition. Every operation of potting, soil mixing, stopping, was carefully recorded in a book for future reference. This year with only about 130 plants, he was able to exhibit twelve blooms at the October show of the National Chrysanthemum Society, twenty-four at Portsmouth, seventy-eight at Southampton, and twenty-four at Winchester, securing seven firsts, one second, and one third prize; also winning at Southampton two silver medals, one as the most successful exhibitor in the gardeners and amateurs division (beating in that several well-known gardeners), and a silver medal in the division open to amateurs only. Mr. Brown, who was only forty-seven years of age, was very greatly esteemed by many horticultural friends. He was also a very popular member of the Hampshire Imperial Yeomanry, of which he was the regimental sergeant-major.—C. S. F., in *Gardeners' Chronicle*.

# THE GARDEN

No. 1622.—VOL. LXII.]

[DECEMBER 20, 1902.

## A MEETING OF ROSE GROWERS.

**O**N Thursday in last week the National Rose Society held its annual meeting, which is always one of the most refreshing events of the busy horticultural year. This meeting was more vigorous than usual, and one left the room with a sense of satisfaction that the society, with its excellent past, is likely to have an even more creditable future. A full report is given on another page, and from that it will be seen that there was a sheaf of proposals of one sort and another, but to us the words of the chairman, Mr. C. E. Shea, were quite as weighty as the demands for a two days' exhibition and for postponing the date of the metropolitan show from the first to the second week of July.

It was necessary this year to use the guarantee fund to save a financial deficiency; the falling off in the attendance at the Temple show was attributed to the Rose conference shortly before at Holland House and to the illness of the King, with which we in part agree, but something may be said for the monotony, not to say tiresomeness, of many present-day exhibitions. The chairman told the Rose Society to wake up and model the exhibitions more upon the lines of those abroad, and "cater for a wider public." He urged the importance of showing the Rose in pots, as climbers in full flower glory, arches, and in every way to please and instruct those to whom the serial ranks of specimen blooms are of little interest.

THE GARDEN has never wearied of urging the framers of schedules and all interested in the various societies in these isles to give as much variety to the displays as is consistent with financial considerations. We are aware of the difficulties to face, but Mr. Shea's remarks were quite opportune, for the society is looking for support, not to the exhibitor merely, but to those who care little whether certain flowers of Anna Olivier or any other variety have a better "finish" than those in the neighbouring stand.

When we write this it must not be inferred that we wish Rose exhibiting were a thing of the past, for we take great delight in these annual tournaments of flowers, and hope shortly to start a series of articles on the fascination and recreation accruing to such a quantity the second day of the exhibition will pursue, but the larger and increasing number of amateurs who have no ambition to win from membership.

prizes but are interested in the show provided for their inspection must be considered, too, and the flower represented in its most charming aspects.

At the Temple shows of the Royal Horticultural Society the beautiful Rose displays are the centre of admiring crowds, and the lovely climbing hybrids and others there shown in pots should be seen in all their beauty at the exhibition of the National Rose Society, which has no other object than to encourage the general culture of the flower.

The excellent secretary, Mr. Edward Mawley, in the report of the past year, referred to the increase in the number of subscribers. The subscriptions are as follow: 1898, £373; 1899, £384; 1900, £391; 1901, £458; 1902, £566; and the strength of a society is in the number of its supporters, which in the present instance totals 890.

The National Rose Society is accomplishing quietly a great work in issuing to the members simple treatises about the culture of the plants, and the official catalogue—the fifth and revised edition of which has recently appeared—is a trustworthy guide, with selections of varieties for exhibition, standards, pillars, arches, walls, bedding and pot culture. We believe these pamphlets to be a tower of strength to the society, as the advice there given is so simple that the intelligent beginner is enabled to avoid failures which growers in the past had to overcome by a long and an expensive experience.

The question of holding a two days' show was again brought forward by the Rev. J. H. Pemberton, who warmly supported the innovation on the grounds of greater financial profits from the exhibition, and that a wider public would enjoy the flowers. We think the experiment worth trying, but of course the exhibition blooms on the second day would not be worth one farthing to see, and to encourage a second day attendance under present conditions would be unwise. We have visited Rose shows throughout the land, and sometimes when the weather is seasonable the flowers have collapsed almost before they have been passed by the judges. The glorious silver medal flowers praised in the papers on the morning following the first day will be glorious no longer, but a huddled mass of rotting petals. Unless the trade come forward with their generous support and bring pot plants in quantity the second day of the exhibition will cause much complaint and perhaps seceders

We wish the question of an autumn exhibition had been pressed more vigorously, for this would be distinctly an amateurs' show, and appeal to those members of the society who are not interested in competitions. It was remarked that the past autumn was unusual, but surely all Rose growers know that the Tea and Hybrid Tea, and China and other groups are not in their richest beauty till the cool days of September and even early October. As the list of new varieties extends this autumn beauty of the Rose becomes even more manifest.

During the past year the society has lost, through the death of that enthusiastic amateur Mr. C. J. Grahame, a supporter whose counsel at this period would have been of much benefit, for Mr. Grahame accomplished for the small exhibitor what we should like to find in the near future achieved for those who have no desire for a prize bloom display. Mr. Grahame's determination to upset the whole system of Rose exhibiting as then prevailed has resulted in a large accession of those amateurs who, through force of circumstances, could not fight those blessed with greater opportunities. May this principle be thoroughly adhered to in the future, and then the society will prosper.

It will interest rosarians to know that the late co-secretary, the Rev. H. D'ombraim, though of advanced age, is in good health, and, in writing this, the great work of this rosarian in the past for the welfare of this society, which he founded, is recalled to mind. Though, in the natural course, diligent workers amongst the flowers leave the ranks, their good works are not forgotten.

We congratulate the National Rose Society upon the annual report presented by Mr. Mawley, and rejoice that its affairs are managed with zeal and discretion.

## NOTES OF THE WEEK.

### FORTHCOMING EVENT.

December 29.—Meeting of the National Sweet Pea Society, Hotel Windsor, 4 p.m.

**The Flageolet Bean.**—Mr. P. Isherwood, The Gardens, Criche, Wimborne, is anxious for information about the Flageolet Bean. We shall be glad if any who have cultivated this Bean will be so good as to send a note concerning it; many of our readers, we feel sure, would be interested also.

**Intermediate house Rhododendrons at Kew.**—The group of Rhododendrons comprising the several Malayan species and the numerous varieties raised by the intercrossing of these species by Messrs. Veitch is a very

beautiful and valuable one. Not only are many colours found in this group which are not found in other evergreen Rhododendrons, but their flowering time is much longer, for while most flowers are borne during autumn, winter, and spring, with a collection of twelve or twenty varieties, it is seldom that flowers cannot be found at any time of the year. The mere fact that these plants make such a bright display at the dullest time of the year commends them to our notice, and many thanks are due to Messrs. Veitch for having been instrumental in first introducing the species and afterwards working on them to produce so many lovely hybrids. At the present time one of the most pleasing features in the Mexican house at Kew is a large group composed of these plants. At Kew, previous to the erection of the Mexican house, these Rhododendrons were grown in pots, but on the completion of the house they were turned out of pots and planted in a border. The border is well drained and made up with peat and sand, about two parts of the former to one of the latter. To ensure thoroughly good drainage the bed was terraced by using large tree roots, so having the compost at different heights. When planting care was taken to ram well the soil about the roots and also that they did not become dry. The result is that the plants now grow more vigorously and flower more freely than they used to do in pots, and at the same time they grow into more shapely specimens. A large number of varieties are to be seen, of which a few of the most showy at present are Brilliant (carrying three dozen heads of flowers), Scarlet Crown, Virgil, Triumphans, Duchess of Edinburgh, Mrs. Heal, Ruby, Aphrodite, Princess Beatrice, Souv. de J. H. Mangles, President, Maiden's Blush, and Princess Alexandra. Cultivators who have not been satisfied with these Rhododendrons in pots would do well to try them planted out in a house with a minimum winter temperature of from 48° to 50°, taking care to give them plenty of drainage, good supplies of rain water at the roots, copious syrings overhead while growing, firm planting, and good sweet soil. The outlay in the first place is a little more than when pots are used, but this is made up for by better plants and more flowers.

**Veratrum californicum.** — In Mr. Mules' article on page 411 in THE GARDEN of last week for inches please read feet. The spike of the Veratrum figured is therefore 8 feet high, and for tea-green (page 410) in description of *Lilium nepalense* read sea-green.

**Berberis japonica and B. nepalensis.** — I was pleased to see the illustrations in THE GARDEN of the 6th inst. of these two Barberries and accompanying note from Mr. Burbidge, as it is strictly in accord with my own knowledge of them. Mr. Burbidge states that the two are for some reason or other frequently confused together in both nurseries and private gardens. This is indeed the case, and, what is more, in the "Kew Hand List" they are considered synonymous, for under the head of *Berberis nepalensis* the following names occur: *Berberis Bealei*, *Berberis Bealei planifolia*, *Berberis japonica*, *Berberis leschenaultiana*, *Ilex japonica*, *Mahonia intermedia*, *Mahonia japonica*, *Mahonia napaulensis*, and *Mahonia Sieboldii*. My experience is that *Berberis japonica* is the hardier of the two, but as stated *B. nepalensis* is the more effective. Where this last is not hardy it is well worth attention as a shrub for the cool conservatory. Years ago when the Royal Horticultural Society was located at South Kensington there was a fine specimen in one of the glazed corridors there, and it remained indifferent to London smoke and dust till it was, in common with many other interesting relics, finally swept away.—H. P.

**Brussels Sprout Sutton's Dwarf Gem.** — This vegetable is in season now, and my note is sent to show the excellence of the compact growers compared to the large and coarse ones. For private gardens large coarse and often loose Sprouts are out of place, and though much depends upon the culture the variety is of much importance. Though with field culture for market a large Sprout is not disliked for the home, I

would advise a bullet-like Sprout of medium size. This season Brussels Sprouts have been somewhat luxuriant in rich old garden soils owing to the abundant moisture during growth. This specially refers to those plants raised under glass early in the year. For ordinary use I would advise sowing Dwarf Gem as early in the year as possible in the open ground or in the northern counties in a cold frame. Plant out when quite small in drills so that the seedlings may be readily watered. Plant 3 feet apart between the rows and there need be no loss of space, as it is quite easy to grow a quick crop between, such as salads or Spinach. Grown thus the Dwarf Gem produces a beautiful hard Sprout with little waste, and, what is so useful, the Sprouts are of excellent flavour and remarkably hardy. Their solid growths from the base to the crown are remarkable for a dwarf plant.—G. WYTHES.

**London Dahlia Union.** — The following letter has been addressed to the National Dahlia Society by Mr. P. W. Tulloch, Sterndale, New Church Road, Hove, Sussex:—"At the annual meeting of the London Dahlia Union, held on November 4 last, at the Royal Aquarium, the chairman (Mr. John Green) announced his intention of giving a ten guinea challenge cup, to be competed for in the premier amateur class for Cactus Dahlias at the annual exhibition of the London Dahlia Union, the cup to become the property of the winner if won for three consecutive years. This liberal offer of Mr. Green's places the London Dahlia Union in a position to offer a considerably greater attraction to amateur exhibitors than the National Dahlia Society. Although the supporters of the Dahlia are doubtless united in wishing success equally to both societies, I feel sure that the members of the National Dahlia Society would regret to see this society placed in a position of secondary importance, and I therefore venture to suggest to my fellow members that an endeavour should be made to raise the sum of twenty guineas by subscription, for the purpose of offering two ten guinea challenge cups, one to be offered in the premier Cactus Dahlia class for nurserymen, and the other in the premier Cactus Dahlia class for amateurs, the cups to become the property of the winners if won for three consecutive years. The National Dahlia Society numbers 160 members, and if each member would be willing to subscribe 2s. 6d., a sum of £20 would thus be raised, which I shall be happy to increase to twenty guineas, in addition to paying the expenses of the printing and sending out of this appeal and acknowledging all subscriptions sent to me. Although a member of the committee of the National Dahlia Society, I may say that I am making this appeal simply as a private member of the society to my fellow members. All subscriptions sent to me will be duly acknowledged and handed over to our hon. treasurer, C. E. Wilkins, Esq., together with a list of the subscribers and the amount of each subscription. Might I venture at the same time to make another appeal, which is that each member of the society should make an effort to introduce at least one new member for 1903? If this could be accomplished and each new member subscribed no more than 5s., the result would be an important addition to the income of the society, thus enabling better prizes to be offered at the annual exhibition, which could hardly fail to increase the competition and improve the all-round quality of the exhibits."

**Chrysanthemums of decorative value.** — It may be of use to some of your readers who do not care to grow the enormous blooms seen at shows, and who do not succeed in doing so, to know the names of a few that are easy to grow, and, without the process bewildering to the amateur, of "taking" the various buds. Owing to a mistaken order, all my Chrysanthemums this year were flowered from terminal buds, that is, they were grown on quite naturally—merely disbudded and well fed. Those that succeeded and have been most decorative for bringing into the house or for cut flowers are Vivian Morel, Lady Hanham, Sunflower, and Chatsworth. They have had a dozen really fine blooms on each plant, and not too tall. John Shrimpton is very

effective, a mass of crimson blooms though not large. Mme. Carnot and Mrs. Mease are charming grown in this way, though quite unlike their usual form, being very spidery and delicate. Edith Pegram, single rich pink, was very fine. Framfield Beauty, a single bronze flower, good. W. H. Lincoln and Niveus are excellent. They were grown in the open, cut round with a spade, lifted in a week's time, and kept close with mats round them and then brought in and not disbudded much. A Pink Niveus that I see as I write has half a dozen blooms each 7 inches across. It is quite an acquisition, being of the same form and substance as the white (so useful for cutting), but is flushed with pink. The failures were Mrs. Coombes, Edith Molyneux, Le Grand Dragon, J. Upton, and others, all of which had open centres and of poor substance. Mme. E. Rogers also came small. Among the outdoor successes this year were Ryecroft Scarlet, which comes first in merit; Robbie Burns, yellow, flushed pink; October Queen, much the same colour as Lady Hanham; Crimson Marie Massé, bronze and yellow; and a beautiful single yellow, which is only just over (December 12), the name of which I do not know. Marie Massé was a disappointment this year, growing very tall and straggly, and of an unpleasing lilac shade. Ryecroft Scarlet is low, compact, and bushy, the colour resembling brick-red rather than scarlet.—A. M. M., Berks.

**Fruit growing and general gardening in Ireland.** — A number of County Committees of Agriculture and Technical Instruction require the services of itinerant instructors in fruit growing and general gardening, and with a view to securing suitable instructors for these positions the Department of Agriculture invite applications from young Irishmen who have had experience in fruit growing and gardening, and who are prepared to undergo an examination, which will be held at the Albert Institute, Glasnevin, at 10 o'clock a.m. on Friday, January 9, 1903. The department are further prepared to employ, with the ultimate object of training them to become instructors in fruit growing and general gardening, a limited number of candidates who, while not reaching the required standard, have shown in the examination a certain degree of proficiency and promise. For the services of suitable itinerant instructors in fruit growing and general gardening who may be appointed, the remuneration offered varies from £2 to £3 per week, according to qualifications, together with expenses of locomotion. Full particulars and forms of application to attend the examination at the Albert Institute, Glasnevin, which must be forwarded to the Department not later than January 5, 1903, may be had from the Secretary of the Department of Agriculture and Technical Instruction for Ireland, Upper Merrion Street, Dublin.—*Irish Times*.

**Sutton's First Crop Cauliflower.** — It often happens that there is a deficiency of autumn-sown plants that will produce early spring Cauliflowers; there is no better time than the present (December) to sow seed to make up the deficiency. For a few seasons we have grown First Crop with such success that a note may not be out of place at this season. I have also grown this variety in pots and boxes, and on account of its compact habit it is excellent for forcing. Seed sown in a cold frame and grown on will produce heads as early as the autumn-sown plants. Our method of culture is varied. Some plants are planted out and grown in cold frames from start to finish; others on a sheltered border, turned out of pots and for a time protected with hand glasses; these follow the frame plants. I am sure few vegetables are more appreciated than early Cauliflowers, and by sowing now this vegetable precedes the Pea crop, and being of such splendid quality is much liked. (Grown in frames they require a rich root run and take up little room, but need care at the start. The seed should not be sown too close, and the plants grown near the glass. It is well to make two or three sowings from now to April, as these will provide a succession of compact heads; the variety under notice has few outer leaves.—G. W.

**Barleria cerulea.**—A great number of Acanthaceous plants are remarkable for their showy blossoms, many of which are produced during the autumn months. Among them are the members of such popular genera as Aphelandra and Eranthemum, to the last of which this Barleria bears considerable resemblance, forming as it does a rather erect-growing plant, with the principal shoots terminated by a cone-like head of bracts, from whence the flowers protrude. These flowers are of a beautiful shade of sky-blue (a decidedly uncommon tint), and though in common with their allies they do not last long, yet a succession is kept up from one head for a considerable time. In the "Kew Hand List" this species, which is a native of India, is referred to as *B. strigosa*. It is somewhat strange that these beautiful Acanthads, of which there are so many, are, except in a botanic garden, rarely met with, for they are of very easy propagation and culture. The reason probably is that they are not available for cutting, a standard by which nearly all plants are judged nowadays. A second species, *Barleria flava*, also a native of India, has bright yellow blossoms; hence, in this respect, it is widely removed from the preceding.—H. P.

**Ampelopsis Veitchii.**—Seeing what remarkably good service this delightful Virginian climber has rendered to gardening, as well as to the picturesqueness of even modern suburban residences, I can by no means join in the disposition shown in some quarters to depreciate it. Even when it is urged that it does to some extent hide the architectural features of houses, whether ancient or modern, it is not difficult to reply that a good deal of architecture beloved of the architect is much better if hidden, whilst so close-growing is the plant that in all good architecture the close, dense leafage which follows so keenly the outlines of the building on which grown seems rather to improve the lines than to spoil them. But, apart from such considerations, how much do town dwellers compelled to live and move amidst streets of raw brickwork or stucco owe to this climber in relieving garishness, and in giving to houses otherwise reeking with summer heat a pleasant coolness? The introducer of this Ampelopsis will never need a worthier or more cherished memorial.—A. DEAN.

## KEW NOTES.

### INTERESTING PLANTS IN FLOWER.

#### Temperate House.

*Acacia urophylla*, *Chrysanthemum indicum*, *Cytisus filipes*, *Dahlia imperialis*, Malayan Rhododendrons, and *Oreopanax sanderiana*.

#### Palm House.

*Acokanthera spectabilis*, *Brownea Crawfordii*, *B. grandiceps*, *Carlindovica rotundifolia*, and *Sterculia mexicana*.

#### Orchid Houses.

*Angraecum eburneum*, *A. pertusum*, *Bulbophyllum rufinum*, *Calanthe Veitchii*, *C. vestita* var. *luteo-oculata*, *C. vestita* var. *rubro-oculata*, *Cattleya labiata* var. *dowiana*, *C. luteola*, *Cirrhopetalum makoyanum*, *Cymbidium giganteum*, *C. tracyanum*, *Cypripedium crossianum*, *C. fitchianum*, *C. insigne* and yellow variety, *C. leeanum*, *C. Morganiae*, *C. venustum*, *C. virens*, *Epidendrum cooperianum*, *E. fragrans*, *Laelia anceps*, *L. autumnalis*, *L. a.* var. *atrorubens*, *L. gouldiana*, *L. rubescens*, *Macradenia lutescens*, *Maxillaria nigrescens*, *M. setigera*, *M. variabilis* var. *media*, *Odontoglossum crispum*, *O. gloriosum*, *Oncidium cheirophorum*, *O. raniferum*, *Polystachya tesselata*, *Restrepia maculata*, *Selenipedium loogifolium*, *S. porphyreum*, *Sophronitis grandiflora*, *Zygocolax amesiana*, and *Zygopetalum cochleare*.

#### T Range.

*Amasenia calycina*, *Barleria flava*, *Clerodendron umbellatum*, *Clivia Gardeni*, *Debregeasia velutina*, *Eranthemum Andersoni*, *Euphorbia fulgens*, *Ipomoea Horsfalliae* var. *Briggsii*, *I. ternata*, *Jacobinia chrysostephana*, *Justicia calycotrichia*,

*Lindenbergia grandiflora*, *Oxalis rhiziformis*, *Paeonia Boldus*, *Picrella excelsa*, and *Thunbergia grandiflora*.

#### Succulent House.

*Aloe arborescens* var. *frutescens*, *A. pluridens*, *Crassula rubicunda*, *Epiphyllum truncatum*, *Rhipsalis crispata* var. *purpurea*, *R. rhombaea*, *R. setulosa*, and *Senecio macroglossus*.

#### Greenhouse.

*Carnation Triumphant*, *Centropogon lucyanus*, *Cinerarias* (garden varieties), *Coleus thyrsoideus*, *Epaeris* (in variety), *Erica melanthera*, *Hibbertia dentata*, *Luculia gratissima*, *Peristrophe speciosa*, *Primula Forbesii*, *P. obconica*, *P. sineesis* varieties, *Reinwardtia trigyna*, *Senecio grandifolius*, and *Strobilanthes isophyllus*.

## NOTES ON LILIES.

### BORDER LILIES.

**C**OMPLAINTS are often made of failures in Lily culture, caused, in many instances, by injudicious selection, for in the books devoted to this beautiful class of plants there is a great tendency to call attention to the merits of all of them, whereas some are extremely difficult to grow successfully, while others may in most soils be associated with ordinary border plants. Given a well-drained and fairly open loamy soil that is not parched up during the summer, the following Lilies will, in most parts of the country, do well:—

*Lilium bulbiferum* grows about 2 feet high, the orange-red flowers being borne in an erect open head early in June.

*L. candidum* (the Madonna Lily).—Part of the recent want of success attending the culture of this Lily is undoubtedly due to the necessity of early planting being so often ignored. While the bulbs should at the latest be planted before August is past, I have seen them three months after that time exposed for sale in a dry state. It is not surprising then that these, when ultimately planted, fall a prey to all kinds of disease.

*L. carniolicum*.—The small Turk's-cap-like light red flowers of this Lily are less showy than some of the others, but blooming as it does among the earliest it is on that account valuable.

*L. chalcedonicum* flowers during the first half of August, and the prettily recurved bright sealing-wax red blossoms are much admired, while they are also less heavily scented than some of the others.

*L. croceum*, the old Orange Lily as this is called, is, about the end of June or early in July, much admired by reason of its erect bright reddish orange-coloured flowers.

*L. darwicum*.—Under this name or the collective title of *L. umbellatum* there are many varieties, all of which flower in June. The flowers, which vary in colour from dark orange to deep red, are borne in erect crowded heads.

*L. elegans*.—Of this there are many varieties, differing in height, colour, and other particulars. Most of them are dwarf, and need to be grouped in the front part of the border.

*L. longiflorum*.—In the southern counties of England this does well as a border Lily, the silvery trumpets being under such conditions much admired.

*L. pomponium*.—This flowers at about the same time as *L. carniolicum*, but the plant is of more slender growth, with deeper and brighter red flowers.

*L. pyrenaicum*.—This, if left alone, forms dense masses about 18 inches high, each sturdy stem being very thickly clothed with leaves, and crowned by a pyramidal-shaped head of small Turk's-cap-like blossoms, which have a heavy unpleasant scent.

*L. szovitsianum* grows from 3 feet to 5 feet high, and bears, early in June, regularly reflexed flowers about 4 inches across, and of a pale yellow, dotted with purple.

*L. testaceum*.—This, the Nankeen Lily, has been too frequently referred to in THE GARDEN to need anything said in its favour, the tall slender stems crowned by their heads of pretty reflexed nankeen-coloured flowers being so distinct from any other as at once to attract attention.

*L. tigrinum*.—In the early part of August the well-known flowers of this Lily assert themselves, and prove it to be valuable for the open border.

Of the Lilies above enumerated, *L. bulbiferum*, *L. croceum*, *L. davaricum*, and *L. elegans* all belong to the upright-flowered class, and can be depended to bloom well the first season after planting, a remark that also applies to *L. longiflorum* and *L. testaceum*, providing this last is planted before Christmas, as it starts early into growth. The Turk's-cap class, on the other hand, are seldom satisfactory the first season after planting, and need two or three years to become thoroughly established. In the southern part of England the Japanese *L. speciosum* is also a good border Lily, particularly in an early season.

H. P.

## CHRISTMAS FRUITS.

IN the consideration of Christmas fruits, quite a different feeling pervades the mind from that which surrounds the fruits that we hope to be anticipating and enjoying some six months hence. At this time of year our gardens and orchards are devoid not only of fruits but of much else that makes a garden attractive—a place almost to dwell in. While we revel in our home produce of fruits, flowers, and vegetables during as much of the year as we possibly can, it is at the period of the old year's departure and the advent of the new, when our own climate as well as our gardens are usually in the worse possible condition, that our thoughts turn to the sunny south, from whence comes much of the produce of the vegetable kingdom that helps to make life happy.

In the matter of fruits, the contents of the grocer's shop are at this season much more in evidence than that of the fruiterer, though in point of attraction the fruiterer and florist, as should be the case, has priority. But while the grocer is almost entirely dependent upon foreign produce, the fruiterer and florist is only partly so. Nevertheless, in the matter of consumption and commercial value, the dried fruits of the former are by far the most important and popular, being in demand by all classes, even the poorest, for Christmas would not be Christmas without the Plum pudding, and a Plum pudding would not be what it professes to be without Raisins and Currants. Besides the enormous demand for these fruits that Christmas brings with it, we must add others, such as Sultanas, Muscatels, French Plums, Prunes, Almonds, Oranges, Lemons, Figs, Dates, &c., a goodly selection, which, regarded from a botanical point of view, represent five natural orders of plants widely separated from each other in scientific classification, and also very widely distributed geographically. Looking into these products a little more carefully, we find that Raisins, Valencias, Sultanas, Muscatels, and Currants are all the produce of one species, namely,

#### THE GRAPE VINE (*VITIS VINIFERA*).

It is quite unnecessary to go into the history of the Vine, already so well known, but it may be of some interest to briefly review its cultivation and extension for the sake of its dried fruits, which has made such progress in comparatively recent years, producing large crops in Australia, the Cape, California, and other countries. Though Spain commands the market in the best quality of Valencias and Muscatels, occasional consignments of the latter are reported as arriving from California, though both in Raisins and Currants, California and the Colonies cannot compete with Spain, the Greek Islands, and Smyrna; they are able to grow and prepare fruits for their own consumption. The Valencia produce in Denia this year is said to have suffered from the extremely hot and dry season, so that the fruits, instead of filling out into plumpness before being dried, have

withered or dried up on the vines. This accounts for one cause of the increase in price, averaging this year about 1d. per lb. over that of last year.

The method of drying Raisins, Muscatels, and Currants differs slightly in detail, the aim being to dry them as quickly as possible to prevent decay or mildew. The bunches after gathering are spread out and exposed to the sun in such a way that the heat is equally distributed to every fruit. The time thus occupied varies according to the weather and other circumstances, but on an average it may be taken at about fifteen days. After the bunches are dried on one side, they are turned over to complete the operation, and when properly dried are packed in boxes weighing respectively 14lb. and 28lb.

Of late years much improvement has been effected both in the drying and packing, especially in the removal of the stalks, which gives the bulk a cleaner and better appearance. Time was—and that until quite recently—when one of the cook's troubles, especially at the Christmas season, was "stoning" the Raisins, a trouble that is now got rid of by the application of machinery at the extra cost of about 1d. per lb., which is compensated for by the weight of the stones. The fruit is very little altered in appearance by the process. Muscatels, which are almost exclusively used as a dessert fruit, are very carefully dried so as to preserve the bloom, and are imported on the stalks, that is, in bunch form. Those from Malaga appear to be abundant this year, as well as of good quality. They are brought here mostly in boxes of 22lb. each, closely and neatly packed in layers.

Another form of Raisin is that known as the Sultana, which is a "stoneless" or seedless variety, from Smyrna. In the absence of seeds they approach very nearly to the Currant, but their much lighter colour and size distinguish them from that fruit, though in point of size alone some varieties of Currants have of late years been introduced about which some difficulty arose among the Customs authorities whether they were rightly classified as Currants, paying 2s. per cwt. duty, or Raisins, upon which is charged 7s. Like Currants, Sultanas are imported with the small and slender stalks still attached. They are packed in boxes each weighing about 30lb. To the extended cultivation in Smyrna of new Vines of the special variety yielding the Sultana Raisin is said to be due the good quality of much of the fruit now in the market. A good quality of Sultana is judged by the light, almost golden colour, fleshiness, and uniformity of size. Much of the lower class fruit of this description is mixed with small dark coloured fruits, which are absent in the best qualities.

Currants in the market this season are said to be of extremely good quality and abundant in quantity. The estimated Currant produce in Greece this year is put down at 150,000 tons, against last year's 110,000 tons, consequently they are selling at a cheap rate. The term Currant as applied to these small dried Grapes is often confusing to a young child, who is more familiar with the Currant bushes of his own garden. In these days of advanced education, however, the fact soon becomes known that the Currant of the grocer takes its name from its original place of growth, namely, Corinth, of which it is a corruption.

Leaving the Grape Vine and turning to some fruit products of the Rosaceæ, an order specially noted in this direction, we find the dried fruits of certain varieties of the Plum (*Prunus communis*) very much in evidence, especially those commercially known as French Plums and Prunes, of which enormous quantities are now produced and consumed both in Europe and in America. Though the Prune is an extremely wholesome and very nutritious fruit, it is not used in this country to the extent it might be, due, no doubt, to the high price it fetches in comparison with other dried fruits, for it cannot be denied that the flavour of the Prune is as much relished by English people as by those of any other part of Europe or America. For some years past the cultivation of Prunes in California has been considerably extended, and it was thought that this extension might lead to a reduction in the prices of the European produce,

as the American demand would be met by California, thus leaving a larger supply of the Bosnian and French fruit for European consumption. With all this, however, there seems to be but little change in the position of Prunes, taking the world over, except, of course, the fluctuations caused by good and bad seasons. In Santa Clara County, California, where some of the largest Prune orchards are to be found, it has been estimated that an orchard of 300 acres should contain about 320,000 trees, which at maturity should give an annual produce of over 40,000,000lb. of dried fruit.

Under proper cultivation the trees begin to bear at the age of three years; in the fourth year they yield a fairly profitable crop, in the fifth year they should give from 50lb. to 60lb. per tree, which in the sixth year should be doubled, and so on. An average yield of trees in full bearing in Santa Clara County is said to be 300lb. per tree. The principal markets for Californian Prunes are Chicago and New York, while smaller quantities go to Philadelphia and Pittsburg. The produce of the Prune-growing countries has been recently estimated as follows: California, between 80,000 tons and 90,000 tons; Bosnia, 60,000 tons to 70,000 tons; and France, 30,000 tons to 40,000 tons. Of French Plums little need be said, as we all know of their more fleshy character and sweeter taste than the Prune, and that they are used for dessert rather than as a culinary fruit. Though a large quantity of French Plums arrive here packed in boxes, some of the selected or choicest fruits are carefully packed in bottles, as are also the choice Plums from Portugal, known as Elvas, and also Carlsbad Plums, the supply of which is always small.

JOHN R. JACKSON.

(To be continued.)

## USES OF BRITISH PLANTS.

### V.—TILIACEÆ.

LIME (*Tilia vulgaris*).—The common Lime is not indigenous, though we have two native species. No particular use is made of the Lime tree in England, but the inner bark, called "bast," is used for garden matting, and known as "Russian," since it is imported from Archangel. The wood of the tree was formerly used for engraving, but is now superseded by that of the Box tree. Holbein's cuts are said to have been made of it. The flowers supply an abundance of Honey, which is secreted in rather an unusual place, namely, by the sepals, which are boat-shaped, and so hold a considerable quantity in each. It hardly ever ripens its fruit in this country. It may be remembered that the Lime tree supplied the name Linne, usually known as Linnaeus.

### GERANIACEÆ (TRIBE, OXALIDEÆ).

Wood-sorrel (*Oxalis Acetosella*).—The wild Geraniums do not furnish any useful plants, except two or three species cultivated in the garden, as the purple-flowered *G. pratense*, *G. sanguineum*, with crimson or pink flowers, and the naturalised *G. pheum*, with dusky purple, as well as *G. striatum*, the "pencilled" Geranium.

In the Tribe Exalideæ, both the Wood-sorrel and Balsams are cultivated, *Impatiens noli-me-tangere* being found in mountainous situations, as in North Wales and Westmoreland, while the American plant, *I. fulva*, has established itself along several riversides.

The Wood-sorrel, the trifoliate leaves of which illustrate "sleep" very well, is remarkable for the great acidity of its foliage, hence it was formerly called "Wood-sour"; this is due to binoxalate of potash. From the expressed and evaporated juice crystals are obtained and sold as "essential salt of lemons," useful for removing ink stains; but it should be remembered that it is very poisonous, so that those who use the plant for salads should do so with great caution.

### AQUIFOLIACEÆ.

Holly (*Ilex Aquifolium*).—Besides being much grown as an ornamental shrub or for hedges, in which the numerous variegated sorts play a great part, bird-lime is often prepared from the bark of the Holly, the inner green portion of which is

steeped in water and allowed to ferment, when, after some days, it becomes sticky. This, with oil or fat, constitutes bird-lime. The bark has also been used instead of cinchona for fevers. Lastly, the leaves are employed in the Black Forest for Tea. This is not surprising, as Paraguay Tea is made from the dried leaves and shoots of another species of Holly growing in South America, and it often happens that similar properties are found in more than one species of the same genus. The white wood of Holly is much used for inlaying, as in the so-called "Tunbridge ware."

### CELASTRINÆ.

Spindle Tree (*Euonymus europaeus*).—The name is derived from the use for which the shoots are employed, and being a very hard wood it is well adapted for making butchers' skewers. It also makes excellent charcoal. The fruit becomes rose-coloured when ripe, and on bursting liberates the seeds, which are covered with an orange excrescence. This yields a good yellow dye, and a green one with the addition of alum. The berries, it should be remembered, are harmful, having proved fatal to sheep.

### RHAMNACEÆ.

Buckthorn (*Rhamnus Frangula* and *R. Cathartica*).—The berries have been long used as a cathartic medicine, but are rather dangerous. The chief value of the berries, as also of a foreign species (*R. infectorius*) is for water-colours, in yielding "sap-green" and a yellow dye, as also does the bark. The wood is particularly serviceable for making gunpowder charcoal, being very light and easily inflammable.

### SAPINDACEÆ (TRIBE, ACERINEÆ).

Maple (*Acer campestre*).—The chief value of this tree is in the timber, as the wood, being beautifully marked when polished, is employed for furniture. As it can be well turned, bowls, cups, &c., are made of it. The sap of this, as well as of other species (especially the Sugar Maple of North America) contains Sugar, the leaves and young shoots forming excellent fodder. The charcoal obtained from this wood is one of the best.

Sycamore or Great Maple (*A. Pseudoplatanus*) is an introduced tree, being a native of Middle Europe and West Asia. Like the Maple, the wood is good for turning, and when the tree has been pollarded the knotty wood is sometimes beautifully marked, and is useful as a veneer. The juice contains a large amount of Sugar. It is said that 36 quarts of sap have flowed from one tree within a week.

GEORGE HENSLOW.

## CHRYSANTHEMUMS.

### THE COLLECTION AT FETCHAM PARK.

On a beautiful day in the late autumn it was our privilege to visit the gardens of Fetcham Park, Leatherhead, there to view the collection of superb Chrysanthemums which have gained so much notoriety in recent years. Fetcham Park is beautifully situated and covers a vast area. The landscape is also beautifully undulating, and the trees, of a varied character, were looking their best in the glorious autumn garb which they assume at this period. Lovers of all that is best and inspiring in Nature could not, on such an occasion, fail to be impressed with the wealth of autumn beauty to be met with everywhere, and all this within twenty miles of the busy metropolis. The brilliant sunshine and the magnificence of the well-timbered park each contributed to make the occasion a memorable one. Special mention must be made of a splendid Cedar on the lawn near to the house. Its girth 6 feet above the ground was no less than 31 feet 4 inches, and its large and numerous handsome branches extended quite 30 yards from the main trunk of this superb specimen.

The Chrysanthemums, however, were the object of our visit, and as Mr. J. B. Hankey gives so many

facilities for their proper cultivation, cultivators throughout the country owe to him a debt of gratitude for the superb blooms emanating from his garden, which they meet with at various shows in London and the provinces. Mr. W. Higgs, the able gardener and successful exhibitor, has shown the Chrysanthemum world how exhibition blooms should be grown. We should imagine his unbeaten record of five years for incurved blooms is a unique one. This great success has not been achieved without much hard work and persistent attention to the many details of culture, which successful growers know full well is absolutely necessary. It is as a grower of incurved Chrysanthemums that Mr. Higgs has excelled. Of his highly finished globular flowers of incurved form this grower has entered the best and most severe competitions during the last five years, and comes out of the ordeal with flying colours. Of such a result he may be justly proud, and all florists who desire to see high quality represented at the leading shows will endorse the hope that this grower may be spared many years in which to represent the Chinese type of the Chrysanthemum in ideal form. Some 400 plants of the incurved type of the flower are grown here, and, as readers of THE GARDEN will imagine, new sorts play an important part in the collection. The Queen family of incurved Chrysanthemums rather more than ten years ago were the great strength of an incurved grower's collection, but since newer and larger types of the flower have received encouragement from the leading authorities, the giants of earlier days just referred to are relegated to a somewhat inferior position. Mr. Higgs, however, still regards the Queens with favour, and appeared to be well pleased with neatly developing blooms of Lord Alcester, Queen of England, Golden Empress, John Lambert, Empress of India, and John Doughty. Years ago scarcely a board of blooms was set up without the foregoing being well represented, and, as subsequent events have proved, these same varieties have been staged in excellent form by this grower, although small when compared with the newer sorts. Another type of incurved bloom, which a decade since was considered ideal, is that known as the Princess type. This was represented at the shows ten years ago by the parent variety Princess of Wales and numerous sports, but in few instances indeed are they now met with.

We saw some pretty blooms of Violet Tomlin and Miss M. A. Haggas, a pair sent out the same year, and immensely popular at the time. Robert Petfield (silvery mauve), Mrs. R. C. Kingston (pale pink, shaded white), and George Haigh (dull rosy carmine) are a trio which promised well for these older sorts, and were striking evidence of the value still set upon them. Just a little later in the date of their introduction were Globe d'Or, bronzy yellow; Lady Isabel, lavender blush, and very large; Duchess of Fife, white, very large and of deep build; Chas. H. Curtis, the large and popular yellow incurved of globular form; Topaze Orientale, a large and deep bloom of a pale yellow colour; Mme. de Verneuil, light pink, shaded white; and Major Bonaffon, the lovely yellow, with splendidly finished petals, which the National Chrysanthemum Society at one time thought was too much like Chas. H. Curtis and bracketed them together as synonymous, were all in the pink of condition. To intending growers of the incurved varieties the names given above should be conclusive proof of their high standard, as it goes without saying that they would not be in the Fetcham Park collection unless they were consistent and of high merit. Newer varieties were in evidence at every turn, and in this way blooms of Miss Doris Cox, a mauve-pink, similar in build to Robt. Petfield but larger, were highly praised. The same remark applies with equal

force to superb blooms of Miss Nellie Southam, a deep rosy purple flower of large size and good form. The blooms of Mrs. H. J. Jones were opening rather late, but their substance promised to be phenomenal. This is a grand white flower of deep build. George Lock, a mahogany-coloured bloom with a paler reverse, was represented by magnificent flowers, and may be regarded as a grand acquisition. Cecil Cutts, of a deep rich butter-yellow colour, and recently certificated by the National Chrysanthemum Society floral committee, is a large and handsome bloom, and has already proved its value on the exhibition table. Mme. Ferlat, white, large, and its golden-yellow sport, Golden Mme. Ferlat, are two excellent sorts, though rather late. Several plants were in a warmer house to hurry them on. Mr. Higgs believes in stopping these two sorts in May and taking first crown buds; it is the only means whereby they may be had in time for the shows. Mrs. F. Judson, pure white, described by some distributors as a white C. H. Curtis, is a capital sort but rather late. A natural break and first crown bud selection prove too late, and for this reason the plants should be stopped rather early. Another very large white incurved is Mrs. C. Crooks, but the petals and the form of the flower have much of the Japanese trait in their character. Comtesse d'Estoile is another new variety of promise, and to be seen at its best should be stopped in May and first crown buds retained. The foregoing are just a few of the more noteworthy sorts remarked on the occasion of our visit. Some of the plants were very tall indeed, and when arranged in the capacious and lofty houses were near from the glass roof. Various systems of stopping are followed; in some cases a March stopping, with a subsequent second crown bud selection, answers splendidly, but gives very tall plants as a result; in other instances a May stopping and a first crown bud selection appear to succeed equally well.

Mr. Higgs also grows about 120 Japanese plants, and these were in splendid form. A few of the most striking flowers were: W. R. Church, Mrs. Barkley, Mrs. Geo. Mileham, Miss Lily Mountford, Miss Nellie Pockett, Mrs. Greenfield,

Mme. Herrewege, Mrs. Coombes, Mrs. H. Weeks, and R. Hooper-Pearson, besides several other popular kinds. With these plants Mr. Higgs has achieved wonders this season. We reluctantly left the gardens and their beautiful environment, inwardly congratulating the proprietor on the charms of all that was to be seen, and wishing continued success to the enthusiastic cultivator.

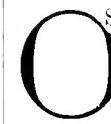

D. B. C.

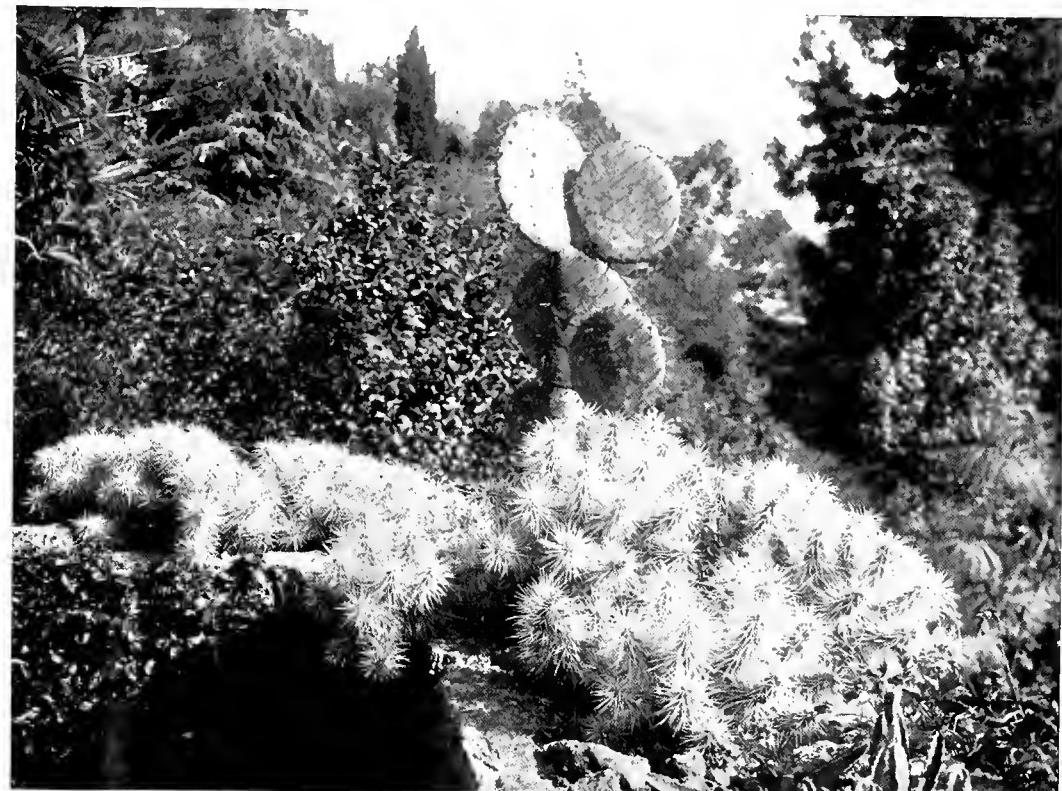

### OPUNTIAS AT LA MORTOLA.

One of the more important features of Sir Thomas Hanbury's garden at La Mortola is the Opuntia. Our illustration shows *O. grandis* and *O. tunicata*, and strangely picturesque are the groups, as the illustration suggests, and the free way in which they are massed gives them a certain beauty.

### THE FERN GARDEN.

#### A NEW VARIETY OF THE ROYAL FERN.

 SMUNDA REGALIS (the Royal Fern) is a distinctly beautiful species, even in its normal form, and when properly treated—i.e., given a boggy soil, or at any rate liberally supplied with moisture—forms a handsome decorative plant. The crested variety, *O. r. cristata*, bearing large flat tassels at all tips, is still handsome, and since its first discovery, near the middle of last century, has been propagated so largely that it is now found in every collection, amateur or botanical. It has also yielded a branched form and a bulbiferous one, though it comes singularly true from the spores. Other finds have been discovered, one with slightly undulate pinnae, and one of an erratic

OPUNTIA GRANDIS AND *O. TUNICATA* IN SIR THOMAS HANBURY'S GARDEN AT LA MORTOLA.

type, but until quite recently the crested form stood alone as an improvement.

Early in August, however, of this year Mr. Alex. Cowan and Mr. W. B. Boyd accompanied a party of botanists to Kerry, Ireland, and there in a district teeming with thousands of the normal Osmunda, they found two beautifully divided types, Mr. Cowan finding six plants in the first instance, which were finely cut and fertile, and Mr. Boyd discovering three others, which were still more finely dissected and barren, pointing indeed to a true plumose type of the species. I send herewith photographs of parts of Mr. Cowan's find, by which it will be seen that, compared with the normal, there is a vast difference, amounting in the upper parts of the fronds to a distinct additional division, the normal smooth-edged pinnules or secondary divisions being cut into stalked pinnulets or tethary ones, giving the frond a far more feathery and delicate appearance. This character pervades the entire frond, appearing in the larger pinnules as rounded lobed edges, merging into stalked pinnulets. Mr. Cowan's form we have named *O. r. decomposita*, reserving a distinctive name for Mr. Boyd's when its character is better established by new growth and further comparison next season. The variety is too thorough to admit of any doubt as to constancy, and we may therefore hail these discoveries as welcome additions to our decorative British Ferns.

#### DECIDUOUS FERNS.

FERNS may be roughly divided into two classes, viz., the evergreens and the deciduous, the former retaining their fronds through the winter until they are replaced by the spring growth, and sometimes even longer, while the latter lose their fronds entirely in the autumn, nothing but the crowns and roots remaining. The consequence frequently is that deciduous Ferns in the hands of those who are not aware of their nature are assumed to have died altogether, the fading and dying down of these fronds being imputed to lack of health instead of to purely natural causes, induced by a habit of resting through the cold season. The major part of the Ferns indigenous to cool and cold climates have acquired this habit, owing to the impossibility of their retaining their foliage in a useful condition through the storms and stress and snowfalls of the winter, and it is only those whose fronds are particularly tough, or which grow under such conditions that these risks are minimised, such as Wall or Rock Ferns, like the Spleenworts, that retain them all the year round. Amongst our British Ferns we have representatives of both classes, the Lady Ferns, Bladder Ferns, Oak and Beech Ferns, Mountain Buckler and Marsh Buckler Ferns, and Royal Ferns. All change colour in the autumn, and eventually die right down to the ground. The soft Male Fern, and Broad Buckler Fern, and its allies spinulosa, uliginosa, and cristata, form an intermediate group, the fronds merely giving way at the base and remaining green in sheltered situations, while the hard Male Fern, the Polystichums (*P. lonchitis*, *aculeatum*, and *angulare*), the common Polypody, the Hart's-tongue, and all the Spleenworts and Blechnums are thoroughly evergreen, as are also the Filix Ferns, *Hymenophyllum unilaterale*, and *tunbridgense* and *Trichomanes radicans*. All these, retaining their verdure as they do, run of course no risk of being mistaken for dead ones, and

consequently neglected in such a fashion that they become so in reality, hence it is only necessary to give a word of warning at this season as regards the former category with a view to their preservation.

In the first place, despite their dormant condition, they must not be allowed to get dry; the roots are still alive and the crowns still full of sap, and these conditions must be maintained. Short of actually standing in water, which is never beneficial, it is difficult to keep them too moist, though it is quite sufficient to see that moisture is retained. If we, at the risk of wet feet, examine the woodland habitats of Ferns in the dead season we find them covered cosily up with wet leaves and in soil which is thoroughly soaked.

removed to the open or quite cold frames when the resting season sets in. None of them like coddling, and most of them, if in a warm house, start growth far too early for their constitution's good, and suffer for it later. The writer's collection is invariably frozen in the winter, whether under glass or not, and in this way obtain a full spell of rest instead of half a one. Those who have warm conservatories, however, and wish to force their Ferny occupants for the sake of earlier enjoyments, may compromise by planting out the Ferns so forced later on in the season, say, end of May, and in this way give them a constitutional which will restore their energies, otherwise they become soft and vermin infested. The main point, however, we have at present in view is that the death and decay of Fern fronds at this time of the year is not necessarily a sign of ill-health, but in all probability is due to a deciduous habit, and hence is quite natural.

#### NOTES ON HARDY PLANTS

##### CIMICIFUGA JAPONICA.

SOME interesting notes have lately appeared in THE GARDEN about this beautiful species, which flowers in Edinburgh about October. The illustration, showing a small plant, was taken in the third week of that month. With age the plants throw up stronger flower spikes. As in the case of nearly all the Cimicifugas, they are of a good white, lasting a considerable period, unless heavy rains and wind occur. This and *C. elata*, which flowers a month or more in advance here, are two of the finest Cimicifugas, and suitable for the representation of this genus in the choicest hardy plant borders.

D. S. FISH.

Royal Botanic Gardens, Edinburgh.

##### DELPHINIUM GRANDIFLORUM.

WE received some time ago a photograph which shows the remarkably free development of this beautiful Siberian plant in the neighbourhood of Chicago, where, in the garden of Mrs. Francis King, Elmhurst, Illinois, it attains a height of between 4 feet and 5 feet. It is a plant that is beautiful in all sizes, for even when stunted and under 1 foot high the dainty shape of both flower and leaf and the brilliant light blue bloom make it a good garden ornament. In England its height is usually from 2 feet to 3 feet. It must, indeed, be a lovely thing in the taller and fuller masses. In a sowing of ordinary seed there are usually some white-flowered plants, and some of a grey-purple colour; it is pretty in any colouring, but best in a limited range of the true Delphinium blues.

##### ORNITHOGALUM UMBELLATUM.

ONE of the commonest of spring bulbs in old gardens is the Star of Bethlehem, with its white satin-like stars with white and green backs, wide open to the sun. So long has it been in our gardens and so willingly does it grow anywhere that it has become naturalised in England, though it is a plant of continental origin. The flowers not only last long in

SPIKE OF CIMICIFUGA JAPONICA, A BEAUTIFUL AUTUMN FLOWER.

This gives us the cue to their natural requirements, and since, in the course of several months, seemingly empty pots in conservatories are very apt to be pushed away out of sight, and hence out of mind, in the absence of any fronds which can be damaged, and the existence of a perfectly hardy constitution, it is advisable to plunge the pots in soil out of doors and mulch them with dead leaves, or to bed them in cocoanut fibre in spare frames. In this way they will be quite safe with an occasional watering, and can be easily reinstated in their proper places as soon as signs of movement are evident in the spring. Hardy Ferns grown in conservatories, which are kept warm in the winter, should, whether deciduous or not, be

water, but if a flower-head is laid on a table without any water it will open its blooms day after day.

#### SAXIFRAGA AIZOIDES AURANTIACA.

THERE is a wonderful wealth of beauty in the Saxifrages or Rockfoils, and we have few genera which add so much to the interest and beauty of the rock garden. They are exceedingly varied in character, and it is not difficult to choose from among them plants which are of the greatest value for any position in which it is desired to plant a Saxifrage. For the vertical or horizontal fissure, for the flat terrace of the rockery, for the border, or for the margin of the bog garden, one or more may be selected which will thrive and delight those who possess them. Some of our native species and their varieties yield to none in their attractions, and among these one would place the variety of our native *S. aizoides*, known as *aurantiaca*, an apt term, from the colour of its flowers.

The typical *S. aizoides* is one which is found in abundance in many of the northern parts of these islands, where it delights to grow in the moist places by the side of little brooks and rills which descend from the hills and mountains. It is, in such positions, a charming little plant, with its close-growing clumps of bright and cheery green foliage, only rising an inch or two above the level of the soil. Its attractions are increased by the flowering period being later than that of a number of the Rockfoils we grow in our gardens, the bright yellow flowers, spotted with red towards the centre, appearing well into summer or even in autumn. The type is always welcomed in the garden, but there is about the colouring of the variety *aurantiaca* a richness and distinctive character which adds still further to its value for us. It may be best described as "old gold," a tint not noticeable in many flowers. There is no more difficulty in cultivating the variety than the type, but it ought to be said that both the typical *aizoides* and the variety must never suffer long from drought. If a dryish position is unavoidable, it ought to be one where the plant is screened from sun and where it can be watered when necessary. With plenty of moisture at the roots it is all the better for sun. There are few prettier moisture-loving Saxifrages than this.

#### PRIMULA MEGASEÆFOLIA.

THE introduction of the beautiful Primula was of great interest to many growers of hardy flowers. It is to be feared, however, that its real value to those who have little or no glass is almost minimised by its winter blooming habit; for in an average, let alone a severe, winter it is hopeless to expect that it will give full satisfaction in the open. Last winter, which, in its early months at east, was a mild one, permitted of this Primula opening some of its flowers, but it never attained the beauty of such a plant as was shown by Miss Willmott at the Drill Hall, and it is doubtful if we shall ever have an opportunity of seeing it in the open in a really perfect condition as regards its bloom. This is meant as applying to winter bloom, but we have been told that it may bloom in summer also. Although my plant in the open was quite healthy and vigorous this summer, and apparently none the worse for its winter without any covering, it made no attempt to bloom until late autumn, when it began to send up its scape of flowers. These were progressing slowly until the frost came in the first week of December and injured them. When this was written the frost was still severe, and it looks as if the plant would require to send up another scape of flowers if it means still to bloom this season. All this points out to

CHRISTMAS ROSES OUTDOORS.

*P. megaseæfolia* being a plant for the alpine house or cool greenhouse, where it can be grown in a pot while it is coming into and while in bloom. For such a purpose it is both interesting and beautiful, not the least of its attractions when grown under such conditions being the fine broad leaves, which, in their general form, justify the aptness of the specific name of *megaseæfolia*, applied from their resemblance to the foliage of some of the Saxifrages of the *Megaseæ* section. So far as regards its hardiness as a plant, I have no reason to complain, as it seems to stand our frosts here quite well. But so far as its usefulness as an open-air flowering plant is concerned, however, I regret that one cannot speak more favourably.

Carsethorn, Dumfries, N.B. S. ARNOTT.

### THE FLOWER GARDEN.

#### THE CHRISTMAS ROSE.

O all our hardy winter flowers this is one of the most useful and interesting, and those who have given their plants a fair share of attention through the growing season, and exercised a little fore-thought in their protection, will now be rewarded with abundance of pure white flowers, which will be warmly appreciated. Christmas Roses flower from the end of the year to the middle of March, as the situation or the weather may determine; this, combined with their purity of colour and hardy nature, makes them doubly useful to the amateur as well as to the gardener. One never need be without these delicate flowers at this dull season of the year if only care is brought to bear upon them. They will grow in almost any ordinary garden soil and in almost any aspect, except full sun. This, from long experience, I have found they do not like. A heavy soil and a shady place suit them well, and it is of the utmost importance to leave them for many years undisturbed, and in the spring, after flowering is over, give a top-dressing of leaf-mould and rotten manure, as this will help materially to keep them in good health for many years.

If the plants are grown in large clumps or in square patches it is well to place one-light frames or hand-lights over them as soon as they begin to make new growth in order to help the flowering, and the same practice may be resorted to for the production of early blooms. These plants also lend themselves readily to pot culture, and should be potted up early in autumn, using pots in proportion to the size of the plants. They should never be overpotted, the soil should be good rich loam, with a mixture of road grit to keep it open. Plunge the plants in frames to their rims in coal ashes or cocoa fibre; this will keep the soil moist and prevent unnecessary watering. The plants may be brought into gentle heat and forwarded as required, but they should never be given very much heat.

After the flowering season is over plunge the plants again up to the rim on a shady border, and during the growing season give them copious supplies of weak liquid manure. I have often seen these plants when grown in pots with all their leaves cut away, and, in reply to the question why this was done, was told the object was to throw all the strength into the flowers. A greater mistake than this cannot be made, for at the time of flowering the plant requires all the help it can get, and as the leaves are the lungs of the plant it is no wonder that after this barbarous treatment we often hear of Hellebores doing badly.

Ashwellthorpe Gardens, near Norwich.

#### ROUND ABOUT A GARDEN.

##### FROST'S DEVASTATING TOUCH.

EVEN the slight frosts of a mild autumn wreck the beauty of a garden. Viewed from a distance many hardy flowers may still make fine patches of colour; but looking close you scarcely find a single untarnished blossom, and only the lucky owner of large glass houses finds no difficulty in the problem of a free supply of cut flowers for the house. Then in December comes the staggering blow of a real

hard frost, and, save for Christmas Roses and some premature Irises, your outdoor garden practically ceases to have any utility as a flower-producing area. Then a melancholy interest attaches to your wanderings among the flower-beds after breakfast, as you note which of your treasures have been "caught" and which, through good luck or good management, have escaped.

#### THE CONSOLATION OF THE BIRDS.

But to those whose joy in a garden is based upon love of Nature, the hardest frost brings the largest compensations. All birds then lay aside their fear of man, and it is something to be accompanied wherever you go by one or other of the robins that have divided up your garden between themselves. So far as his beat extends each will attend your steps, fitting a few yards in front and watching with head cocked on one side as you whittle off a tiny scrap of Almond for him. If the religion of the robins includes any tradition of a Garden of Eden, Almonds that grew without shells must surely have been the forbidden fruit, for when once a robin has learned—though some take a much longer time to learn than others—that you dispense scraps of Almond every day, he becomes your unquestioning devotee.

#### TITS AND ALMONDS.

The tits are slaves to the "Almond habit," too; but for them your best plan is to string whole Almonds on a slack wire, slung between two trees or verandah posts, or uprights of any other form. Tits never seem to be really comfortable at dinner unless they are twiddling head downwards all the time. Scarcely have you hung up the day's supply than a tomtit comes flying from the shrubbery like a bullet, and, without swerve or check in his flight, is fixed upside down to one of the Almonds, grasping an end with each foot and hammering away at the middle with his chisel beak. Before, however, he has got into full swing, another tomtit, slightly larger and more brightly coloured, comes straight across the open to the wire and abruptly alights, not upon any of the disengaged Almonds, which are placed about half a foot apart so as to accommodate all comers, but upon the very Almond which the first tomtit was eating. The latter evades the collision by a miracle; but he must, you would think, be shot into the next parish by the effort. Instead of that you see him calmly commencing to feed again on

the next Almond but one. This does not please the newcomer at all. He lets go of the original Almond, and in the same instant is hanging on to the next Almond but one, while the original tomtit has somehow got into the Honeysuckle above the further end of the wire.

There is another movement, so quick that the eye can scarcely follow it, and both tits are in the Honeysuckle. No, they are not: only the newcomer is there, and the original tit is in the shrubbery across the lawn. Then the newcomer returns to the half-eaten Almond, and, if he is lucky, makes a square meal of it,

not some ill-mannered bachelor from the north. Indeed, if, as is well known, hosts of tits come to England as migrants in winter, how do we know that our own tits do not similarly travel southwards, getting separated from their wives on the journey, and fighting all comers for food throughout the winter?

#### FLOATING BIRD LIFE.

We know that our swallows and nightingales and cuckoos go, because no others come from further north and east to take their places; but how do we know that our blackbirds, thrushes, robins, and tits do not leave us for the winter also, their places being taken by migrants? If those who take interest in the wild life of their gardens would make notes of the individual peculiarities of any birds which are seen there in winter, and keep a sharp look out for the same birds in the following spring and summer, we should probably find that our bird population migrates and changes from season to season much more completely than naturalists imagine. Some robins, for instance, spend only the summer, and others only the winter in a certain district, while yet others only visit it twice a year, in spring and autumn. This explains why your garden robins, which have almost fed from your hand in winter, sometimes seem to grow suddenly shy in spring. They are not the same robins. E. K. R.

IN AN ALGIERS GARDEN: DATURAS IN FLOWER.

end with each foot and hammering away at the middle with his chisel beak. Before, however, he has got into full swing, another tomtit, slightly larger and more brightly coloured, comes straight across the open to the wire and abruptly alights, not upon any of the disengaged Almonds, which are placed about half a foot apart so as to accommodate all comers, but upon the very Almond which the first tomtit was eating. The latter evades the collision by a miracle; but he must, you would think, be shot into the next parish by the effort. Instead of that you see him calmly commencing to feed again on

without being buffeted off by a stranger stronger than himself.

#### A CONTRAST IN MANNERS.

In the end, perhaps, all the tits get as much as they want; but it is interesting to note that the male tomtit—who seems to be the very soul of chivalry towards the female in spring, officiously hunting for the most savoury spiders, which she accepts with the tantalising nonchalance of the sex—should be so boorish in winter. One begins to doubt whether he can really be the same tomtit who nested in the hole in the old Apple tree, or whether he is

they are in England at the approach of winter. French owners of villas always have their gardens filled with trees, too much so for beauty, but it has to be said in their excuse that when one is obliged to spend the heat of summer out here there comes a time when one is quite sick of flowers, and shade is the one and only thing to be desired. In the French villages very good use is made of Plane trees, some of their market-places having really beautiful avenues of those trees, though there is a suspicion—with I do not know how much truth in it—that much of the ophthalmia of the country could be traced to

the pollen blown about from them. But even in the month of August any resident who wished for it, and had water at his disposal, could have his garden full of beautiful flowering shrubs and trees. In fact, we possess in our Jardin d'Essai, which was intended to be, and might even now be, a priceless legacy from the late Emperor and Empress of the French. This garden was founded, as its name implies, to get together, acclimatise, and propagate the flora of all climates and countries, temperate, tropical and semi-tropical, for the good of Algeria; and now that the country is given over to Vine-growing, and it is almost impossible to bring in any plants at all for fear of the strict laws against the importation of the dreaded Phylloxera, we could have turned to an inexhaustible treasury, and taken our choice of flowers and trees to suit every season. But, alas! for lovers of the beautiful, the senseless ingratitude which erased the name "Impériale" from all the improved streets or new boulevards in nearly all French towns; to substitute the misleading words "de la République," succeeded at the time in arresting this good Imperial work of the Jardin d'Essai. Though there are still some beautiful things left in it, for most fortunately what was already introduced might not be dug up, all horticultural and botanical

enterprise has ceased, and it has become a mere market garden for a few easily-grown and readily-sold products.

But to return to the month of August, there was still some natural colour about. The Morning Glory, if that is the true name of *Ipomoea rubro-caerulea*, has long ago escaped from the gardens and acclimatised itself generally in the trees and hedges of the lanes, clothing itself anew every morning with a cool fresh suit of blue, and changing to purple and red before the evening. With this we see constantly associated the common wild rose-coloured Oleander, which, besides being a favourite in most gardens, fringes the banks of every dry watercourse all the way from the slopes of the Djurjura Mountains down to the very edge of the sea. Another great addition to the roadside beauty of the country has come through the enormous growth of vineyards during the last twenty years, and the consequent introduction of the novelties of hedge-rows, of which nothing has been found so suitable as the *Acacia eburnea*, not on account of its graceful pyramidal clusters of bright yellow globe-shaped flowers, nor of its delicious and penetrating fragrance, but for its most effective *chevaux de frise* of thorns, like polished ivory, often 4 inches in length, which make the thirsty wayfarer think

twice before making a raid on the Grapes beyond.

Now, as I write, in the month of December, all is changed again, for there fell in the course of the last month about 14 inches of rain, and I have returned from England to find the gardens with such a good start made for the winter season as they have not had for many years. This means, I hope, a pleasant winter as far as climate goes for English visitors. It is, in fact, the climate of twenty years ago, when Algiers as an English winter resort fancied herself more than she does now. Once more the Bongainvilleas, both the claret-coloured and the beautiful terra cotta-coloured *braziliensis* are out to welcome us back, and the Poinsettias and Daturas double and single. The latter have evidently three special periods of full bloom in the course of the year—March, June, and December. I believe that, like the Stramonium, the flowers of the single *Datura* (*D. Tatula*) has a patent medicinal effect in cases of asthma, for I remember that an asthmatic old carpenter who once worked for me used to beg for the privilege of taking home with him every evening as long as his job lasted all the dead and fallen blossoms of the day. He used to break the shrivelled flower in two and stick the thin end inside the other, and twist them up together in to a

MONSTERA DELICIOSA AND PAPYRUS IN AN ALGIERS GARDEN.

sort of cigarette, to dry for future use, and declared that it was the only remedy that made his nights endurable.

We are enjoying three very delicious sorts of fruit which are now at their best, the Custard Apple, Anona Cherimolia, and also A. squamosa, the latter being the choicer of the two; the green-skinned Plaquinemuse (*Diospyros*), with a luscious apricot-coloured flesh, which has a most soothing effect on the throat, unlike its more brilliant relative the red-skinned *Diospyros* Kaki, which, unless it is on the verge of decay, leaves a very astringent after-taste in the mouth. If I am not mistaken these fruits are allied to the Persimmon of America. But best of all is the fruit of the *Philodendron pertusum*, better known in England as *Monstera deliciosa*. The flavour of this is difficult to describe, but I have just sent off two specimens to your address and hope in this way to convey some idea of it. My largest plant has now a considerable number of its curious thick ivory flowers, like enormous Lords and Ladies, and about sixty fruits of all ages, varying from one month to nearly eighteen, at which period they consider themselves ripe at last, break from their stems, and begin to shed their scales and send out their excellent perfume over the whole garden, an invitation to all the insects, birds, and rats about the place.

I have also sent you a photograph of this plant with a group of Egyptian Papyrus growing at its foot. I am only sorry that the photograph cannot give an idea of the rich chestnut colour of the sheaths out of which the slender stems rise into the air, with their graceful plumed heads; both of those plants enjoying apparently the same treatment—*i.e.*, with their feet in the constant drip of water and their heads in the full blaze of sunshine.

[We are very sorry that the publication of this interesting article has been long delayed. The manuscript was unfortunately mislaid for some time.—ED.]

## THE KITCHEN GARDEN.

### MUSHROOM GROWING IN GARDEN, FIELD, AND COTTAGE PLOT.

(Continued from page 404.)

#### FORMING BEDS.

**U**SUALLY the season for forming Mushroom beds in houses begins towards the end of August. They cannot be satisfactorily grown in these structures in summer (the mode of culture suitable to this period will be treated of later on). The first essential to success is that the grower must be satisfied that the house is perfectly clean and sweet and free from insect pests—such as woodlice, cockroaches, &c. If he is not satisfied, now is his time to make sure, in the first instance, by clearing the house of every scrap of old soil or manure there may have been left from previous crops, and thoroughly to scald all the walls and other surfaces of the house with boiling water several times to make sure that nothing alive can escape. Sometimes these pests lodge in the roof, and the best way to destroy them is by burning sulphur in the house. All that will be left to do now to make the house ready is to have it carefully whitewashed with quicklime. When the manure is brought into the house it should first be placed loosely in the beds, and allowed to remain so for a few hours to let

some of the steam pass away. As soon as this has subsided the grower must then begin to form the bed, beginning at the end most convenient. The same principle of making the bed applies to beds of all shapes, and in various positions, according to the system to be adopted, therefore the mode of making the bed described here will equally apply to forms of beds under other systems. The grower should be provided with a wooden mallet and ram the manure well down as the work proceeds till a depth of 9 inches is secured. After all the available manure is worked up in this way the bed should be as hard as a board, and to make sure that it is so give a good treading down with the feet. A hole should now be dug out (in the middle of the bed) with a small trowel, large enough to place a small thermometer in. After placing it in cover over with manure, and indicate the place with a small label. After the lapse of twelve hours the temperature should be ascertained; it will probably stand at about 80°. If the manure is in proper condition the temperature should rise within the next twelve hours from 85° to 90°; it should be examined again at the end of another twelve hours, when the heat will probably be found on the decline, and as soon as it reaches from 80° to 82° then is the time to insert the spawn. Should it happen that the manure still inclines to rise in temperature then the preparation has been faulty, in so far that fermentation has been defective; and rather than let it overheat itself the bed should be again thrown open to cool and then reformed as before. It is, however, seldom necessary to do this. I shall have to say something about the quality, &c., of spawn when I come to treat of its manufacture.

#### SPAWNING.

Old and partly spent spawn is useless; without healthy and active spawn good results are out of the question.

The size of a brick of spawn is usually 6 inches by 9 inches; this should be broken up by the hand into from nine to twelve pieces, and these pieces inserted in the bed 10 inches apart into small cavities previously prepared for them. These cavities should only be deep enough to

allow the spawn to be embedded a trifle lower than the surface of the bed. The spawning being completed as far as the lumps are concerned, we have still left the loose spawn which has fallen from the bricks in the act of breaking. This should be carefully collected and spread over the surface of the bed. This finished, a thin layer of the same sort of manure as that forming the bed should be spread over the spawn, and the whole surface again well pressed down with the wooden mallet previously spoken of. Further operations for the moment must be governed by the temperature of the bed. If this is steadily declining and has reached, say, a point of 75°, then the bed must be sealed down. By this is meant that a layer of soil (the siftings of turf which has been used for potting is the best material) should be laid over the bed about half an inch thick when finally pressed down. This soil should be, when applied, neither too dry nor too moist, so that it can be trodden down as firm as possible, and then well watered with tepid water afterwards and beaten with the back of a clean spade, so that the surface will appear almost as smooth as if coated over by a plasterer.

For the next month the cultivator will have little or nothing to do in the way of attendance on the Mushroom house. At this time of the year (September) his efforts must be directed to keeping the house as cool as possible, and all that is required is to damp the floor morning and afternoon with cold water. The house, of course, must be kept dark. At the end of a month after spawning the bed should receive a good soaking of water at a temperature of 80° applied through a fine rose water-pot. When I say a good soaking, I mean enough water must be given to soak the crust of soil well through—but not the manure. The young grower must not be too anxious or too curious or look for results too soon.

#### THE CROP.

In about five weeks from the date on which the bed was spawned (the date must be indicated by a label) the grower's heart should be

A PROFITABLE MUSHROOM HOUSE.

gladdened by the sight of small disturbances here and there in places all over the bed, sometimes in irregular patches and sometimes in long thin lines—caused by the activity and running of the spawn, which is soon visible in streaks of white—as if cotton thread were woven over the ground. Every day will now add to the number of those and their size until, if all the conditions are favourable, the whole body of the bed is clothed completely with mushrooms of the finest quality, a sight as pleasing and interesting as any garden crop is capable of presenting.

(To be continued.)

## NURSERY GARDENS.

### MR. R. C. NOTCUTT.

In the late spring of this year, when the self Tulips were proclaiming their splendour, and the Pearl Bush was as white as a snow-drift with blossom, we paid a visit to the beautiful nursery of Mr. Notcutt at Woodbridge, the quaint Suffolk town, where once Fitzgerald lived and endowed it with a literary interest that clings to it as a precious memory of the past. This nursery of Mr. Notcutt's has a certain fascination to the student of English horticulture, for here Mr. Woods grew his famous flowers, and the old house was a meeting place of many an unbending florist, who, wedded to his theories about certain formalities in a flower, forgot, in his rigid conservatism, their value to the garden. The spirit of a bygone age clings to the now much-improved house, and as one looks up to the stately Corsican Pine on the hill top we see around evidence of the fashion of the times in the brave masses of hardy flowers and interesting shrub groups cultivated with the intelligent care that a well-managed nursery always reveals.

Those who wish to spend a few hours in a nursery rich in hardy flowers and trees and shrubs, and with broad acres of Roses and fruit trees beyond the noble parish church, the pride of Woodbridge, might with profit, if in this neighbourhood, stroll round the acres here. We chose the late spring, happening to pass through Woodbridge at this season, and saw Mr. Notcutt's big Tulips open to the sun in bed and border in front of the house. As this is bulb planting time, it will be useful to refer to a few of the species. We write species to separate them entirely from the Dutch Tulips, which are common to almost every garden, but the self or gesner kinds are different. We never pass a group of *Tulipa gesneriana* without full admiration of its glorious flowers, like satiny goblets filled with red wine, through which the sun glows and sparkles.

Unbending is the strong stem which holds this crimson chalice, and as the spring sun warms everything into life the petals open to show the inky base, dark and beautiful in the throat of the flower.

The Darwin Tulips were at their best when we visited Woodbridge, and we made note of Carmine Glow, bright crimson; May Queen, a soft salmon-rose touched with bronzy yellow; Hecla, deep crimson; Golden Crown, the yellow Retroflexa, Picotee, and a sweetly-scented orange-coloured variety named Prince of Austria. These are not all "Darwins," but the majority are of this vigorous race. It is a pleasure to the writer to watch the progress and opening of the late Tulips, the gradual uplifting of the stem, and swelling of bud till it opens in full splendour to the sun, for the colouring of the self or late Tulips is as gorgeous as any flower of summer or autumn. Parts of the nurseries are woodland. One walk enters by the Corsican Pine group and dips into a leafy hollow where in spring drifts of Daffodils appeared above the grass, and rough plantings of shrub lent rugged wildness to the hollows and shady grassy ways.

Through the sighing Pine trees the eye wanders

to the sunlit river by the edge of the town, and the smell of the sea seems mingled with the perfume of flowers.

The Corsican Pine walk is of much interest; it is thirty-five years since the trees were planted, and we got Mr. Notcutt to photograph it for us, as we believe in this Pine for shelter planting, by sea or inland. Near the group was the Austrian Pine, and many other species of value for park and woodland planting.

Of course, it is possible only to mention a few of the things which arrested our attention in a walk round the nursery; but we were surprised by its extent and the completeness of the collections, not merely of trees and shrubs and hardy flowers, but of fruit. Gum Cistuses grow with a freedom irritating to those with soils that

do not quite suit this plant of Heathly copse and woodland. The Maples were there in rich variety, and the Pearl Bush in full flower. This was illustrated in THE GARDEN of September 6 last; the bush stood out in a border untouched by anything near, and thus was able to show its graceful contour and wealth of spotless flowers. It is at home in the lightest of soils. A large Snowy Mespilus, Fern-leaved Beech, thousands of *Cistus laurifolius*, evergreen Oaks, the double Furze, a splendid mass of yellow, a shrub that all who have wild or rough openings in woodland should plant; Weeping Box, *Cryptomeria elegans*, and a host of flowering shrubs and conifers were passed in our ramble, and of the

A sweet whiff of fragrance came from a corner where the Violet Princess of Wales was saturating the air with its perfume. A royal flower is this, royal in its purple colouring, and its petals poised on stalks 15 inches high. Wall-flowers scented the fresh spring wind, and all around was bursting into life.

When spring meets summer then the borders

WALK OF CORSICAN PINE IN MR. NOTCUTT'S NURSERY AT WOODBRIDGE, SUFFOLK.

### HARDY FLOWERS

there is an almost complete collection. *Incarvillea Delavayi* was represented by several large masses, and it is interesting to note that the seed is sown where it is wanted to grow early in spring; it is quite hardy, but there is one point to note carefully, that is, the plant never starts into growth till the end of June, and therefore is apt to get dug up under the impression that it is dead.

The big rosy purple flowers of the

*Incarvillea* are very

handsome. *Lathyrus rotundifolius*, which has brick-red flowers; *Phlox Mrs. Jenkins*, the best white herbaceous variety in existence; *Montbretias* in abundance, *Zauschneria californica splendens*, *Antirrhinum Crimson King*, with dark foliage and deep crimson flowers; *Anemone sylvestris plena*, the double white variety of the Snowdrop Windflower; the new *Campanula persicifolia Moerheimi*, the double *Arabis albida*, the lovely annual *Arctotis grandis*, shown so well by Mr. Notcutt at the Holland Park show, double blue and double pink Hepaticas, the filmy *Heuchera micrantha* with its slender pinkish-flowered stems 2½ feet high; *Anemone japonica* Lord Ardilaun and Lady Ardilaun, *Othonna cheirifolia* and *Delphinium Zalil* are only, of course, a few of the things in the collection. We mention them by name merely to show how representative

are bright with a hundred flowers till the time of Aster and Kniphofia in autumn, a procession of colour never wearying and never satisfying. Leaving this nursery, we walk to the hill above the town, where twenty-one acres are covered with

### FRUIT AND FOREST TREES.

Stretches of Victoria and Czar Plums show the popularity of certain kinds, and close to them Berry's Early Kent, Whinham's Industry, Crown Bob, and Lancashire Bob Gooseberries are grown in great quantities, and Superlative and Norwich Wonder Raspberries too. The Myrobalan is grown largely for hedges, and Mr. Notcutt says that there is a great demand for this sturdy little Plum. These fruit acres are of much interest, because they are evidence of the needs of the age. One quarter is planted with Winter Orange Pear, which recently

was awarded a first-class certificate as a stewing variety by the Royal Horticultural Society, and of Bramley's Seedling, an Apple we have always regarded as one of the best of its class. Mr. Notcutt has exceptional trees in such quantities that the demand for his splendid Apples must increase.

Thus we walk over this breezy hill top and pass golden Elms, trees and shrubs for sea coast gardens, which Mr. Notcutt makes a strong point of; *Cupressus macrocarpa*, *Hippophae* (Sea Buckthorn), *Osmanthus ilicifolius purpurens*, and others, *Cornus Mas aurea elegantissima*, and many things too numerous to mention.

We shall visit here again we hope and learn more lessons. A bright day in an interesting nursery is never forgotten by the writer, and his notes, taken in those flower homes, are useful companions through a busy life.

## MISCELLANEOUS.

### THE HORTICULTURAL COLLEGE.

#### TRAINING OF WOMEN FOR SOUTH AFRICA.

**I**NTEREST with much interest the announcement that the Horticultural College at Swanley has taken up this most important and useful work. If only the training be sound and entirely practical it should have the heartiest encouragement.

The use of ordinary carpenter's tools, which any woman of normal health and strength can acquire, is of inestimable use in any household, still more so on a colonial farm, many miles perhaps from any artificer. To this should be added, as a matter of primary importance, the use of the simplest saddler's or shoemaker's implements. The colonist's wife should know how to mend or even make a whip, how to put a few stitches with awl and waxed end into boot, legging, or harness, how to make and repair fishing tackle. The proper way of "whipping" with waxed twine comes useful in many ways.

All sorts of handy ways of using things should be learnt. An excellent exercise is the straightening of a quantity of bent nails on a block of iron or on a stone (a flat iron turned upside down with the handle let into a block of wood is a capital small anvil). The gardener's way of sharpening a knife, with a little sharp grit on a board, when a hone or "rubber" is not at hand, is a precious piece of knowledge. Right ways of making knots, and the waggoner's way of hanging up a rope, and numbers of simple sailors' and fishermen's ways of using simple things are of inestimable use. Even right ways of using paste and glue and tin tacks should be known.

Nothing in the way of practical knowledge, with the prospect of making good colonists, should be considered too trivial. Above all, the most commonly besetting sin of women of the middle classes should be strenuously combated—that of thinking themselves too grand for this or that, or for anything that can possibly be useful. Nothing is more surprising to women of the classes commonly ranked above them than this spirit of raising absurd difficulties upon matters of no importance; it is universally contemned in people of better education and wider views of life. Sometimes the obstacle is a mere word. An example quite recently came before the present writer of a woman of the servant class who had refused to have her Tea out of a tin tea-pot. The tea-pot was of pure block tin, had cost a good price, it was of remarkably good shape and appearance, and made excellent Tea. It was no use explain-

ing that pure tin was a rather costly metal, and that it was the most expensive ingredient in the "metal" tea-pot of lower price and worse shape that she habitually used, but that was then away for repair—no, the word "tin" condemned it; she would not drink Tea out of a tin tea-pot.

The prospective colonist should not only learn to use her hands and her wits, but should keep in mind the old knightly view of the dignity of simple service, whether of domestic service, of master or mistress, or of home, husband and children, and of Christian service to all humanity. *Ich dien* (I serve), the truly noble motto of our Princes of Wales, and one of the grandest in any language, should be always in her heart and at the tips of her fingers.

A SQUIRE'S DAUGHTER.

#### THE PURCHASE OF ARTIFICIAL MANURES.

(Continued from page 273.)

BLOOD-MEAL, say 12 per cent. nitrogen  $\times$  11s. 9d. = £7 1s., together with about 5s. on account of a little phosphate.

Rape-meal, say 5 per cent. nitrogen  $\times$  11s. 9d. = £2 18s. 9d. per ton.

The values per ton for these three manures are considerably higher than the merits of the manures would warrant. These manures, in fact, are only worthy of a farmer's attention, under ordinary circumstances, when they can be bought at a rate per unit of nitrogen that is considerably less than that which applies to nitrate of soda or sulphate of ammonia.

Phosphatic manures are also valued in the same way. At the present time the insoluble phosphates in basic slag are valued at about 1s. 3d. per unit, and at this rate a sample containing 40 per cent. may be put at  $40 \times 1s. 3d. = £2 10s.$  per ton, carriage paid, while a 30 per cent. sample is no better value at 37s. 6d. As a rule, the lower grades cost more per unit than the higher qualities, so that the latter are usually the better value.

The soluble phosphate of superphosphate may, at present, be valued at about 1s. 9d. per unit. At this rate a 28 per cent. sample would cost 2f 9s. per ton, carriage paid, while a 34 per cent. sample would be as good value at £2 19s. 6d.

In bone-meal—which should only be bought when very finely ground, really dust—the nitrogen is usually valued at about the same rate as that in sulphate of ammonia, while the phosphate may be put at the same rate as that which prevails for basic slag. On this basis, a sample containing 4 per cent. nitrogen, and 50 per cent. insoluble phosphates, would work out as follows, though it can often be bought for less:  $4 \times 1s. = £2 4s.$ ;  $50 \times 1s. 3d. = £3 2s. 6d.$ ; total, £5 6s. 6d. per ton, carriage paid.

In dissolved bones the market rate for nitrogen may be put at that which prevails for nitrate of soda, while the rate for the insoluble phosphate is usually the same as that in bone-meal. The soluble phosphate in this manure is exactly the same substance, chemically, as that in superphosphate, and yet it is generally valued about 1s. per unit higher. The only justification for this would appear to lie in the fact that the insoluble phosphate, being partly reverted, should be valued somewhat higher than that in raw bone, and raising the rate for the soluble phosphate makes some allowance for this. Taking these figures, and assuming a good sample of dissolved bones, we come to the following result: 3 per cent. nitrogen  $\times$  11s. 9d. = £1 15s. 3d.; 20 per cent. soluble phosphates  $\times$  2s. 9d. = £2 15s.; 16 per cent. insoluble phosphates  $\times$  1s. 3d. = £1; total, £5 10s. 3d. per ton, carriage paid. Although this is about the market rate for dissolved bones, it would appear to be higher than their intrinsic merit warrants.

Kainit can usually be bought at the rate of 4s. per unit of potash, so that on an analysis of 12½ per cent. of potash the price of a ton, carriage paid, would be  $12\frac{1}{2} \times 4s. = £2 9s.$

Sulphate of potash, containing 25 per cent. of

potash (corresponding to a purity of about 46 per cent.), would at the same rate be worth  $25 \times 4s. = 5$ ; while high-class manure, containing, say, 40 per cent. of potash (corresponding to a purity of about 74 per cent.) would be worth  $40 \times 4s. 3d. = £8$ . In point of fact it is generally found that in the higher grades of sulphate of potash the unit-value of potash is somewhat higher than that in kainit, so that, with kainit at £2 9s. per ton, the market value of sulphate of potash of a purity of 74 per cent. is likely to be about  $40 \times 4s. 3d. = £8 10s.$  With a light haulage, and especially if the manure can be applied in autumn or early spring, so as to admit of certain undesirable magnesia salts being washed off, kainit is usually the preferable manure; but for use at seed-time, and especially when mixed with other manures, sulphate of potash has advantages.

Muriate of potash is usually placed on the market of a purity of 80-90 per cent., corresponding to 50-57 per cent. of potash. Taking the former quality, and adopting the unit-value of potash in kainit, the price of a ton would work out at  $50 \times 4s. = £10$ . Generally a unit of potash in muriate is valued at a lower rate than that in kainit or sulphate of potash, so that the market quotation per ton is likely to be about  $50 \times 3s. 9d. = £9 7s. 6d.$  Muriate of potash, in fact, usually offers the cheapest supply of potash, and for most crops it is probably as effective as any potash manure, while for Potatoes it would seem to be superior.

The most important example of a manure holding nitrogen, phosphate, and potash is Peruvian and similar guano. The composition varies within wide limits, but the following may be taken as an example: Nitrogen, 12 per cent.  $\times$  11s. 9d. = £7 1s.; soluble phosphates, 5 per cent.  $\times$  1s. 9d. = 8s. 9d.; insoluble phosphates, 15 per cent.  $\times$  1s. 3d. = 18s. 9d.; potash, 2 per cent.  $\times$  4s. = 8s.; total, £8 16s. 6d.

Such a manure, however, would probably be priced at a much higher rate, so that guano, like bones, would appear to be still under the influence of past traditions.

It may be pointed out that the purchase of manures at a certain rate per unit, subject to analysis by an approved chemist, makes a farmer largely independent of variations in quality. If, for instance, he agrees to pay 1s. 3d. per unit, including carriage, for phosphates in basic slag, it is a matter of comparative indifference to him whether the consignment proves to be of 35 per cent. or 40 per cent. quality. In the former case the price per ton would be  $35 \times 1s. 3d. = £2 3s. 9d.$ , while in the latter case it would be  $40 \times 1s. 3d. = £2 10s.$ , and the value would be as satisfactory in the one case as in the other. Needless to say, he would not apply the manure to his land till he was in possession of the analysis, and then he would regulate the dressing with some regard to the quality of the material.

J. J. WILLIS.

## THE FRUIT GARDEN.

### FRUIT IN SEASON.

#### APPLE DR. HARVEY.

**M**RS. FIELD sends from Ashwellthorpe Gardens, Norwich, fruits of this excellent Apple, which we shall figure shortly. It is of conical shape, about 2½ inches high, a trifle broader, almost smooth, and yellow with dabs of russet, the flesh yellowish, brisk, and agreeably flavoured. Some would esteem it for dessert, others for cooking. Our correspondent sends the following note: "Apple Dr. Harvey is a great favourite, and is extensively cultivated in this locality. The tree grows to a large size, is very hardy, and a most prolific bearer. The fruits always find a ready sale, and realise a good price."

## KENTISH PIPPIN.

Mr. Field also sends fruits of this Apple, which is about the same size as Dr. Harvey, and reminds one a little of Cox's Pomona. It is flushed with red, and round the eye are five knobs, which extend into somewhat prominent ribs; the flesh is white and acid, but not unpleasantly so. Mr. Field writes: "This is another Apple that does well in this neighbourhood. The tree is strong and vigorous, large, and bears abundantly, and the fruit is eagerly sought after in the markets. With these two kinds and others quite as good, it is vexing to find many of our orchards and gardens still crowded with worthless sorts, some of which rarely produce anything, and when they do so the fruit is almost valueless. When will the farmer and cottager wake up to the fact that good Apples need no more space and grow in the same soil and far better than bad ones?" With these remarks we quite agree, and have given this advice repeatedly till those who have followed it must think its repetition wearisome. But fruit growing in these isles is in its infancy.

## A NEW APPLE.

## APPLE NORFOLK BEAUTY.

A SPLENDID new early cooking Apple is Norfolk Beauty, the result of a cross between Warner's King and Waltham Abbey Seedling. It is a large and handsome fruit, of flattened conical shape, a good yellow in colour, almost equal to Golden Noble in this respect. It should prove a good succession Apple to Lord Suffield. Mr. Allan, head gardener to Lord Suffield, Gunton Park Gardens, Norwich, exhibited this new fruit at a meeting of the Royal Horticultural Society held on the 9th inst., when the fruit committee gave it a first-class certificate. An award of merit was given to it last year.

## THE BEST PLUMS FOR WALL CULTURE.

THE following are specially recommended for culture on walls, and most of them are distinct and first quality dessert Plums. I have included a few, distinguished by their large and noble appearance, which may not strictly be termed dessert sorts, seeing that they succeed well as dwarfs, pyramids, and standards in the open ground, and so cultivated are excellent for culinary purposes, but the improvement effected by wall cultivation in the size, quality, and flavour of these varieties is so great that it raises them in value to such a degree that their inclusion among the best for dessert and exhibition purposes is justified.

## THE GAGE VARIETIES.

These are numerous, and all distinguished by high quality and delicious flavour, and among so many varieties that possess this merit it would seem invidious to point out any one special variety as possessing this particular quality in excess of the others, but the truth must be told, and speaking from my own experience I readily give the palm for delicious flavour to Denniston's Superb. In addition to this it has the merit of being one of the earliest of the Gages, and hangs for a moderately long time on the tree if securely protected from birds, &c. It attains to a good size; in outline it is nearly round, of a greenish yellow colour, and the tree is an excellent grower, succeeding well as a cordon or a pyramid, but the fruits lack the size and quality obtained when grown against a wall.

*Old Green Gage.*—To well known and appreciated for its splendid qualities as one of the most delicious dessert Plums to need further description. The tree is a strong grower, and in its young stages requires guarding against gross growth by root pruning.

*Brahy's Green Gage.*—This is a fine exhibition variety of large size and excellent flavour, very much like the old Green Gage, but larger and earlier.

*Brandy Gage.*—This is of medium size to small, colour yellow, with dense white bloom; ripe in August; flavour melting and sweet.

*Bryanston Gage.*—This is a fine hardy Gage, succeeding well in the open, but deserving also to be included amongst wall Plums, as grown in this way it attains a good size, and is fine for exhibition.

*Ondlin's Golden Gage.*—Very handsome early variety, which should be included in every collection, also succeeds well in the open, even as a standard in the orchard.

*Purple Gage.*—For variety of colour in the Gages this Plum should be grown. It succeeds well against a wall, and is one of the sweetest of Plums. It does not succeed so well planted in the open.

*Coe's Golden Drop.*—As a late dessert Plum this well-known variety is perhaps the most valuable and highly prized of all known dessert Plums. Planted against an east wall the fruit is ripe towards the end of September, and if properly protected against birds and wasps the fruit will hang on the tree until well into November, and the flavour, instead of deteriorating, is improved by this long hanging, until at last the flesh is transformed into almost a liquid elixir of exquisite delicacy and flavour. A few trees should be planted against a north wall in order to prolong the season, and should hard frost be apprehended whilst the fruit is still hanging on the tree it may be picked and carefully placed in the fruit room, where it will last in good condition for a considerable time. The variety is a good grower and cropper, and I would advise its being largely

APPLE NORFOLK BEAUTY. (First-class certificate, Royal Horticultural Society, December 9. Three-quarters natural size.)

*Comte d'Attrem's Gage.*—One of the best late Gages, the tree a good grower and sure cropper.

*Golden Transparent Gage.*—Another very excellent and indispensable late sort, raised by Messrs. Rivers, and awarded the first-class certificate of the Royal Horticultural Society.

*Transparent Gage (New Early).*—One of the best flavoured and richest dessert Plums we have, of large size, and grand for exhibition. First-class certificate of the Royal Horticultural Society.

*Reine Claude de Baray.*—This is the most prolific and hardy of all the Gages, and succeeds well in the open, either as a standard, pyramid, or bush. It crops as freely as any Plum I know, after the tree has attained a fair age. This of all the Gages is the one to grow for market purposes, for in addition to its robust growth, hardy character, and good bearing qualities, it has the true Gage flavour and appearance.

*Transparent late Gage.*—A new variety of great promise, raised by Messrs. Rivers and Sons; it has received the first-class of the Royal Horticultural Society, and will prove invaluable for late dessert.

planted, as the fruit comes in most useful in the late autumn when Peaches and Nectarines are over. This Plum was a great favourite with Her Majesty the late Queen Victoria, and if not sent in for dessert at the usual time she would always want to know the reason why.

*Transparent Gage.*—This is an old variety (and distinct from Early and Late Transparent), and should be included in every collection, as in the estimation of many, taking it all in all, it is one of the finest of the Gages.

*Jefferson.*—This fine Plum is too well known to need description. It is one of the handsomest and best flavoured among our large Plums, indispensable both for dessert and exhibition.

*Kirke's Blue.*—Also one of the best known Plums and perhaps the handsomest among the dark ones. A good grower, heavy cropper, and of delicious flavour.

*Reine Claude Violette.*—A purple Plum of medium size and exquisite flavour. Well worth planting against a wall.

*Washington.*—A well-known variety and in-

valuable for exhibition purposes, being one of the handsomest of the golden-coloured sorts. The tree is a robust grower and free cropper.

The following are, strictly speaking, culinary sorts, but when grown against a wall are admissible as dessert and for exhibition purposes are invaluable:—

*Archduke*.—One of the handsomest dark Plums, much improved in flavour when grown on a wall and good for exhibition.

*Monarch*.—Well known as a grand late variety, and esteemed by market growers as the most lucrative sort to grow for sale. Suitable for the orchard or garden, and when grown against a wall is good for dessert and grand for exhibition. Colour purple.

*Royal English*.—This also is much improved by wall culture, and seeing it is one of those varieties which hang for a long time on the tree when ripe it comes in useful for late dessert. Dark and handsome.

*Royal Hatire*.—A dessert Plum of great merit, medium size, and one of the richest flavoured of the purple varieties.

*Pond's Seedling*.—A very attractive red Plum, attaining immense size when grown on a wall, and fine for exhibition.

*White Magnum Bonum*.—When grown against a wall this is the handsomest of yellow Plums, and makes a most attractive dish, either for the dessert or the exhibition table. The twenty-four varieties above enumerated represent the best dessert varieties suitable for wall culture. Varieties for the garden and orchard I must leave for another article.

A. P. H.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

## THE SWEET POTATO AND YAM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—During the period of stress which our Sugar-growing colonies in the West Indies are passing through, pending the abolition of the foreign Sugar bounties, the attention of the planters has naturally been given to other produce. In Barbados great success has been achieved in the cultivation of Sweet Potatoes and Yams of the very best quality, and an endeavour is now being made to introduce these into this country. The Sweet Potato is a cheap and palatable vegetable, but a good Yam is a positive luxury.

During a long residence in London I imported several barrels every year for my own use, and out of the numerous guests who tasted them at our table there was not one who did not highly appreciate them. I may add that here the flavour is even more delicious than in the West Indies, as Butter, which is a vital ingredient in a well-cooked Yam, is so much better.

I am returning to Barbados almost immediately, but any information on this subject will be given by Messrs. W. Pink and Sons of Portsmouth, who are importing regular supplies. Recipes for various ways of cooking both Sweet Potatoes and Yams are sent out with every parcel.

F. M. ALLEYNE,

Member of the Legislative Council of Barbados.  
*Junior Carlton Club, London.*

## STILL (?) OCTOBER.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—A prettily written article appeared in these pages a few weeks ago under the above heading, minus the query, in which the writer, after suggesting that "old-fashioned Christmases, all icicles and robins," &c., are only figments of the imagination, dilated on the stillness of October. One sentence runs: "The charm of the tenth month is its stillness." Perhaps the locality in which I reside differs from the rest of England in its

atmospheric conditions, for with the experience of a good many years I should certainly hesitate to add the prefix of "still" to October. That there are quiet windless days I admit, and those that take their pleasure in the open air in such a spell of calm might be led to conclude that calm was characteristic of the month, but might not this also be a "figment of the imagination?" Still days there may be, but a week of halcyon weather does not make a still month. Smarting under the injury inflicted by a heavy south-westerly gale, which tore the Michaelmas Daisies from their stakes, wrenched off the leaves and flower-heads of the great Crinums, and laid Abutilon vitifolium level with the earth, I read the article landing October's stillness with a wry smile, and wondered whether this was an exceptional October, and if it was normally a still month. I seemed to remember other October gales, but vagaries of the weather, unless they approach in gravity the memorable blizzard of March 11, 1901, when thirty-six trains were snowed up in the south-west, soon pass out of mind, and for the last half decade or so I had kept no records wherewith to refresh my memory. Some years ago, however, I was in constant touch with a well-equipped meteorological station, and my notes on the weather, gathered from this source, appeared monthly in *THE GARDEN*, and to these I turned to discover the character of October in the past. I found that though in one year there were only two months stiller than October, an average of the series gave it the seventh place out of the twelve months for wind-force, while in the year that included the windiest October there were only two months more boisterous. Although by no means proving a still month in the average wind movement, October's status as regards highest hourly velocity comes out even worse, strong winds or gales being registered almost annually, while on one occasion, about twenty years ago, the greatest wind-force of the whole year was recorded. My remarks are not intended to apply to the British Isles as a whole, but only to the south-west coast. In other parts October may possibly enjoy a well-merited right to be entitled "still," though I confess I doubt it.

S. W. F.

## GARDENING OF THE WEEK.

### INDOOR GARDEN.

#### HOTHOUSE PLANTS.

PLANTS that are resting, such as Allamandas, Clerodendrons, and Dipladenias, may be stored in an intermediate house during the winter. They should be examined occasionally, and but little water given to the roots during the period of rest. Gloriosa superba, which is resting, may be stored in the pots away from moisture until the time comes round for starting it again.

#### GLOXINIAS.

Summer-sown seedlings that are coming into flower should be given a moderately dry atmosphere. Later plants in small pots that are well rooted should be moved into larger pots. Thorough drainage, dry and clean pots are necessary, together with a light porous compost of fibrous loam, leaf-soil, and peat; add also coarse silver sand and a little finely broken charcoal. In potting avoid covering the centre of the plant, but the leaves may be allowed to rest on the soil. Keep the plants in a moist warm atmosphere with a temperature of about 55°.

#### PALMS.

At this season of the year too much water at the roots is most injurious to these plants, and every care should be taken to give sufficient only. The necessary moisture in the atmosphere should be provided by damping the floors and stages; the plants should be thoroughly overhauled and the foliage sponged.

#### ROSES IN POTS.

A succession of these plants should be removed indoors, and but little fire-heat given at first. The

plants should be syringed until the shoots are about an inch long, and the moisture from evaporation will generally be found sufficient; the plants must not be crowded. In the early stages of growth they should be kept rather dry, but as growth progresses the supply of water should be increased. A careful watch should be kept for insect pests, and prompt measures taken to eradicate them.

#### GENERAL REMARKS.

Constant attention must be paid to the overhauling of stored bulbs, such as Caladiums, Gloxinias, Gesneras, &c. Drying off is frequently practised wrongly. These plants as soon as they have done flowering are often put on one side, and very little care bestowed on them until the season for growth comes round again. It is important, however, that they should not be dried off too quickly, and when stored away must never be baked; this, like too much moisture, will often cause the loss of the bulbs.

Wexham Park, Slough.

JOHN FLEMING.

## THE KITCHEN GARDEN.

### THE FRAME YARD.

If not already done lose no time in turning over into tidy heaps old and disused hot-beds, which will make excellent material for giving many of the kitchen garden crops a good start in the new year, and a general clear up should be made in this important part of the garden before the end of the year.

#### HOT-BEDS.

These should be built up largely now, and they are best made with good leaves, using just sufficient long stable litter to hold them together. Great care should be exercised not to plant or sow when the heat is too great. Far better err on the side of its being cool than otherwise. The mildest heat possible is sufficient for starting into activity such as Potatoes, Carrots, Radishes, Asparagus, and the like, and if the beds are properly made the temperature can easily be raised by adding fermenting material as lining to the frames. It is a good plan to arrange so that Potatoes and Carrots follow Asparagus, there being generally plenty of warmth left to give these a start.

#### VACANT GROUND.

Take advantage of any frosty mornings to get all the manure, &c., wheeled where required, as this means a saving of much labour and mess. Push forward digging and trenching as speedily as possible, especially so on light soils. Do not be afraid to bring the subsoil to the top. Endeavour to make as deep a root run as possible, which is certain to pay in the end. Leave the surface in a lumpy condition, making no attempt to break it up; the weather will do this better than we can. Plants being wintered in cold frames should have plenty of protecting material round and over them in severe weather, but advantage should be taken on all favourable occasions to air them freely, and remove all decaying leaves and rubbish.

#### TOMATOES.

Make a small sowing in a strong heat of some good variety for fruiting early in the spring. As soon as young seedlings appear place them on shelves near the glass, and pot off into 2½-inch pots as soon as ready. Use a light sandy compost well warmed, and endeavour to encourage as sturdy a growth as possible from the seed leaf till the plants are in fruit, and so much better will be the returns. Plants which are now in flower will need careful and constant attention to ensure a free set.

Maintain a temperature of about 60° and keep as dry as possible. The flowers should be fertilised daily and the roots kept moderately dry. Those in full bearing will succeed best in a temperature of about 65°. Keep both foliage and roots moderately dry, and give manure water occasionally. Of roots of various kinds which are still in the ground sufficient quantities should be taken up and stored where easily obtainable to last for a few weeks in case of severe weather; the roots will comprise such as Artichokes, Parsnips, Chicory, Salsify, Scorzonera, Turnips, *Stachys tuberifera*, and Celery.

IN THE ROCK GARDEN AT BEAR WOOD, BERKSHIRE, THE RESIDENCE OF MR. A. F. WALTER.

Rhubarb roots which will be required for forcing should also be lifted. Celery should be protected with Bracken or straw whenever the glass is likely to register anything below 12° of frost, but this should be removed whenever the weather will allow. Lift all Broccoli which shows signs of turning in and store in cold sheds or frames.

E. BECKETT.

*Aldenham House Gardens, Elstree, Herts.*

#### THE FRUIT GARDEN.

##### PRUNING BUSH APPLES.

The bush and Pyramid forms of Apple trees are now very commonly planted, and when properly managed they are very prolific and produce fruit of excellent quality. A common mistake made in the management of these trees is that of allowing the branches to become crowded. This can easily be guarded against in the case of young trees by cutting out shoots which cross others better placed, also cut out those that incline inwards. In pruning a tree, the object should be to have a foundation of branches inclining away from the stem, with enough, but no more, side branches to furnish it properly. If this was borne in mind and carefully carried out during summer pruning, all that now remains to be done is to shorten the young growths to about two-thirds of their length, in order to form spurs and sufficient subsidiary

branches. Prune to an upper bud pointing outwards. In the case of established trees thin unduly crowded spurs, and do not hesitate to cut out misplaced branches.

##### STANDARD TREES.

Young trees of this description should receive similar treatment to that advised for bush trees, and old trees should have their branches thinned if necessary. It is not advisable, however, to severely thin in one season. It is better to allow the work to extend over a few years, as severe treatment in such cases invariably causes a check.

##### DRESSING FRUIT TREES.

Once pruning is completed, cleaning the trees of insect pests, lichen, &c., should be taken in hand, as this can be best done in the winter. In the case of those affected with American blight, remove the loose bark beneath which the aphis has secreted itself, and then apply petroleum emulsion by the aid of a suitable brush to the affected places, thoroughly working the insecticide into the crevices, &c. The best remedy to free trees from scale, the eggs of destructive moths, lichen, and moss is undoubtedly the now well-known preparation of caustic soda and potash. This is best applied by spraying the trees with it in a hot state in mild weather, taking care that the entire surface of the bark is reached. Freshly slaked lime dusted over the trees when they are damp

will eradicate lichen and moss, but the soda and potash solution is more efficacious.

##### MISCELLANEOUS WORK.

During frosty weather farmyard or stable manures, charred refuse, wood ashes, and similar material may be conveyed to orchards or other plantations of fruit trees or bushes that require nourishment. Sewage manures, that are at this season not unfrequently allowed to waste, may also be utilised in favourable weather by being applied to wall or other trees and bush fruits that have exhausted their soil resources. It is an error to suppose that these nourishing manures are of little or no value to trees while they are apparently in a restful state.

##### ORCHIDS.

##### HEATING, DAMPING, AIRING, &c.

In the Phalaenopsis, stove and warm Cypripedium houses maintain a temperature of 70° by day and 65° by night. No air should be admitted when the weather is very cold or cutting winds prevail. When the weather is mild a little should be admitted by the lower ventilators. Damping these houses is of the utmost importance at this season, for a dry parched atmosphere would be highly injurious to the occupants and favourable to the increase of insect pests. A too moist atmos-

sphere must also be avoided, as this would be injurious in other ways. The outside conditions must be considered and moisture distributed accordingly. When wet and mild, damping once a day may be quite sufficient, while if excessively cold twice or three times may not be too often to counteract the drying influence of the hot-water pipes.

#### THE CATTLEYA HOUSE.

Where the majority of plants are in a state of rest anything that would unduly excite growth should be guarded against. If a temperature of 65° by day and 60° by night is provided the plants will pass through the winter safely. Much less moisture is needed in these houses. One had better err on the side of dryness rather than have the atmosphere too moist. A little air should be admitted by the lower ventilators if the outside temperature is above 35° and it is not windy.

#### THE MEXICAN HOUSE.

Should receive similar treatment to the Cattleya house, but the temperature may fall a few degrees at night, 60° to 65° by day and 55° to 60° by night being all that is needed, as the occupants of this house are like the Cattleyas (inactive), and need a long season of rest. The Dendrobiums, wardianum, and the nobile section, too, rest well under these conditions until showing their buds, then rather more heat is necessary.

#### THE COOL INTERMEDIATE HOUSE.

In this a great number of plants are growing. Miltonia vexillaria, &c., Cymbidiums, and Sophronitis grandiflora have not yet finished. A little more moisture in the atmosphere is needed than in the Cattleya or Mexican houses, but this must not be carried to excess. A temperature of 65° by day and 60° by night should be maintained, and a little air admitted by the bottom ventilators when the outside temperature is not below 35°, and increased as the outside temperature rises.

The house containing the cool section of Cypripediums, *C. insigne*, for example, should have a temperature from 55° to 60° by night and 60° to 65° by day, a moderately moist atmosphere and the lower ventilators a little opened when the temperature outside is not below 35°. The

#### ODONTOGLOSSUM HOUSES.

should now be artificially heated to 55° by night and 60° by day with a moist atmosphere, guarding against an excess of wet if mild, and avoid anything approaching a dry parched atmosphere when excessively cold. Admit air by top and bottom ventilators if mild, when cold by bottom only, and never entirely close the house unless there is a frost. The Odontoglossums of the crispa section are growing freely and many pushing their flower-spikes. If slugs are troublesome, cotton wool should be placed neatly and somewhat loosely around the base of the spikes (slugs will seldom pass over this). Valuable plants showing their spikes should be stood on inverted pots in pans of water, and see that the plants do not touch anything whereby slugs can gain access to them. This section of Odontoglossums seldom fails to produce spikes, which, if allowed to remain and bloom every year, will greatly weaken the plants; if allowed to bloom every alternate year it will be better for them, as the health of the plants must be the first consideration, especially the more valuable kinds. They should therefore be examined at intervals, and as soon as the spikes are visible pinch them out from all weakly plants and those that bloomed last year.

#### CLEANING THE HOUSES.

This is important, and cleaning the plants far more so. Orchids cannot be kept too clean, and this will now occupy the greater part of the cultivator's time. When cleaning a house remove all plants in order to prevent water getting into the axils of the leaves, which to many plants would be injurious at this season. It is best to do the dirty work first and clean afterwards. First scrub the pots as the plants are taken from the house, then the roof, walls, and staging. If the latter are of teak wood they should have a coating of boiled linseed oil, which will greatly preserve them. Clean

the glass inside and out, sponge and clean every plant thoroughly and return to their respective positions, and so arrange them that each may get an equal share of light.

#### COVERING THE HOUSES.

Where lattice blinds are used lower them on all the houses on cold nights, or cover the cool houses with mats. This will, to some extent, do away with fire-heat and economise fuel.

## BRITISH HOMES AND GARDENS.

### WOODHATCH, REIGATE.

THE late Mr. T. B. Haywood's love of horticulture and the interest he took in the art as a means of recreation and rest from his large and absorbing business are well known. This is also evident by the beautiful garden he has created at Woodhatch. Efficiency and simplicity of working seem to have been the guiding principle in all he undertook. This is specially manifest in the building and arrangement of his many glass houses, as well as of the hardy fruit and vegetable gardens. No one can help but be impressed by the clever and ingenious way in which the glass houses and the utilitarian part of the garden have been effectively concealed from the house by planting, though but a few yards distant. The pleasure grounds surrounding the house may not inappropriately be termed a pleasure garden within a pleasure garden. This part of Surrey is a veritable and beautiful garden in itself, on all sides hills and dales abounding, clothed by rich and luxuriant vegetation and noble trees in great variety. On one side of the public road near the house is one of the handsomest Maidenhair trees (*Salisburia adiantifolia*) we have ever seen. It is from 60 feet to 70 feet high, and at the time of our visit gave one the impression of being a huge column of gold, from the colouring of the dying leaves.

Entering the gates the house is approached by a beautifully curved drive, flanked on either side by banks of trees, one tree especially being worthy of notice, a beautiful Beech, one limb of which, instead of growing upwards in the usual way, has spread out horizontally, spanning the drive completely with a cordon of pleasing foliage. Facing the entrance hall door is a charming bit of garden landscape, a glade of grass rising gently until in the distance its apex forms the sky line. A few specimen trees have been thoughtfully planted here and there, but not in sufficient numbers to mar the effect or lessen the beauty of this pretty glade, each side of which is planted with ferns and other trees now of large dimensions.

The late Mr. Haywood's interest in horticultural matters was not confined to his garden at home. He was for many years a member of the council of the Royal Horticultural Society, and took a warm and practical interest in its welfare. The garden charities also found in him a good friend. He was for some years treasurer of the Gardeners' Orphan Fund. But we question if any horticultural event or function of the year gave himself and Mrs. Haywood greater pleasure than the annual visit of horticultural friends to see his Chrysanthemums, Orchids, Pelargoniums, and other winter-flowering plants in bloom and to partake of his and Mrs. Haywood's boundless hospitality.

These were days of real enjoyment to his guests, as I am sure they were to the hosts. Horticulturists will be pleased to know that the same interest is taken in gardening by Mrs. Haywood and her only son (now the head of his late father's firm) as was shown by Mr. Haywood, and the same welcome and hospitality extended to horticultural friends. It was on the 4th inst. that such a party visited Woodhatch, and after luncheon were escorted over the garden by Mr. Haywood, going first into the Odontoglossum houses, where the plants, although

of course out of bloom at this season, looked the picture of health, and gave promise of a rich return in bloom next spring. The Vanda and Cypripedium house was the next to receive attention, and much of interest was to be seen, a fine plant of *V. sanderaiana* being in bloom, many choice Cypripediums, and a host of tiny seedlings in all stages of growth. Coming to the Dendrobium house, the visitors were highly pleased at the excellent health and condition of the plants, such clean, firm, and free growth is seldom seen; they were mostly seedlings raised at Woodhatch. The Cattleya, Masdevallia, and Phalaenopsis houses were next visited, and afforded the visitors much pleasure and interest, especially the Phalaenopsis, the plants being excellent, many showing strong flower spikes. We noticed also that Pleione in variety (Indian Crocus) and the pretty white Masdevallia tovarensis were grown in quantity.

Winter-flowering Pelargoniums are always a great feature at Woodhatch, a span-roofed house being devoted to them. No plant gives a more cheerful and brilliant effect from November to Christmas than does this, and nowhere is the plant better grown. The Chrysanthemum was a special favourite of Mr. Haywood, and the collection at Woodhatch is well known to have been (and is still) one of the best and most complete in the London district.

Fruit under glass is not extensively grown, but hardy fruit is well represented, and not the least of the pleasures of the visit is a call at the well-equipped and excellent fruit room, usually brimming full of well-grown and well-coloured fruit, offering to the expert fruit growing visitors an excellent opportunity of comparing notes as to the merits of the flavour of those Apples and Pears which may be in season at the time.

Some gardeners might possibly view with unpleasant apprehension the annual visit of so many horticultural experts to examine critically and admire (or not admire) the result of their skill and labour year by year, not so with Mr. Salter, the head gardener; on the contrary, we believe he anticipates their visit with as much pleasure as his employers, and this says much for his skill, industry, and competence in managing the Woodhatch garden. Much more might be said of the extensive pleasure grounds surrounding the house, and the rare and beautiful trees with which they are planted, as well as of the flower and Rose gardens, also of the model farm and stables, but enough has been said to give the reader at least some idea of Mrs. and Mr. Haywood's beautiful home.

O. T.

## BOOKS.

**Easily-grown Hardy Perennials.**\* This is quite an amateur's book about hardy plants, and will prove helpful, as the information is clear and practical. It is profusely illustrated, but the author cannot be congratulated altogether upon his publisher. Some of the pages are badly printed and the illustrations far from satisfactory; but the amateur desires practical advice, and this will not be sought in vain.

**The Amateur's Greenhouse**, from the same publishers, is written by Mr. T. W. Sanders, and it is almost needless to write that for the beginner and amateur in general the work is excellent, as Mr. Sanders' books are already well known. Many amateurs will welcome this volume, especially at this season when our thoughts turn from the garden outdoors to the garden indoors, where Pelargoniums and other winter flowers bring sunshine to the home. There are chapters upon construction, heating, the proper plants to use, &c., and we feel certain that "owners of small greenhouses will find the book a practical and reliable guide to the management of the greenhouse and the successful cultivation of its contents." The book is better printed than "Easily-grown Hardy Perennials."

\* "Easily-grown Hardy Perennials." By G. H. Vos, B.A., and edited by T. W. Sanders. Price 5s. W. H. and L. Collingridge, 148 and 149 Aldersgate Street, London, E.C.

# THE GARDEN

No. 1623.—VOL. LXII.]

[DECEMBER 27, 1902]

## HORTICULTURE IN 1902.

WITH the present issue another year draws to a close, and we again review the horticultural events of the past twelve months. The year has been full of incidents, as our pages show, and it is evident that the horticultural calling is of unceasing activity and importance, events occurring in rapid succession in all parts of the British Isles, with an all-round desire to acquire a knowledge of gardening for the sake of health and wholesome recreation.

The great event, perhaps, of the year has been the adoption by the meeting, convened by the Royal Horticultural Society, of a Hall as a suitable means of celebrating the fast-approaching centenary. *THE GARDEN*, though desirous of acquiring proper trial-gounds for the society, gave every assistance in its power to the council in its efforts to raise the large sum of £40,000, but the recently-shown plans have met with disapproval so strong and sincere that if persisted in as they are at present, those who have subscribed will have many misgivings as to the wisdom of their practical assistance.

Many influential Fellows have still to give, and the council will be wise to take heed of the sharp and well-merited criticisms of those who are deeply interested in all that concerns the society to which they belong. The Hall should show beauty of design and practical utility, and prove a building horticulturists from over the seas can regard with feelings of pleasure and pardonable envy. Several meetings have been held, all presided over by the President with rare tact and charm.

Another great event was the beautiful Coronation show held by kind permission of the Earl of Ilchester in the park of Holland House, and the private gardens were opened also on special payment in aid of the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund, but the serious illness of the King threw a deep gloom over the proceedings, and, we may say, the whole Coronation festivities. The Rose conference was a great success, and the papers read by the many authorities will be treasured when they appear in the society's valuable journal.

The Temple Gardens were again the scene of two great exhibitions, the Royal Horticultural Society's May display presenting much the same features as in previous years, but the

visit of their Majesties and Princess Victoria will be remembered with pleasure. The exhibition of the National Rose Society, as we mentioned last week, was a financial failure, but a Rose show in London has had the excellent effect of greatly increasing the list of subscribers, which means a firmer foundation for the whole structure.

The meetings of the Royal Horticultural Society in the Drill Hall have been interesting and varied. We look back upon this year in particular with pleasure, having in mind the many displays which have brought together large and interested crowds. Never have Roses made a braver show in autumn than this year, and we hope the National Rose Society will take heed of the fact and establish a competitive display for September.

The National Chrysanthemum Society has held its last show in the Royal Aquarium, which has been acquired for other objects, and we hope a suitable home will soon be discovered for the three great exhibitions which have attracted much attention in the past.

The weather has tried the health, patience, and temper of the gardener, whether amateur or otherwise. Cold winds and rains until June was far spent prevented growth, and the Apple crop proved a complete failure, whilst few other fruits were satisfactory. An absence of flavour in almost all fruits was noticeable, due to want of sun and a low temperature.

In reviewing the past year our thoughts turn to those who have gone from our midst, but whose work among the flowers remains a pleasant memory. Of amateurs devoted to their gardens we mourn the loss of G. F. Wilson, of Weybridge; of Dr. Stuart, of Chirnside, who raised many beautiful Pansies; of C. J. Grahame and Horace Radelyffe Dugmore; and of nurserymen, William Bull, of Chelsea; and, among others, Charles Maries.

Again we heartily thank those friends of *THE GARDEN* who have helped us in the past, and with this help in mind we set forth with renewed courage for the work of another year, for without our many contributors, those who have long been associated with *THE GARDEN* and those we may claim as new friends, our work would be weary and dispiriting. Again we especially thank those who kindly send occasional notes to interest and instruct readers who need the helpful guidance of amateurs able to give advice.

The British nation is at peace, at least free from serious strife, and with this welcome

thought in mind we are justified in hoping that the year so soon to begin will bring increased prosperity and widespread happiness to all our dominions.

## THE HORTICULTURAL HALL.

### THE PLANS.

It is to be hoped that an affirmative answer may be obtained to the editorial query "Is reconsideration possible?" prefixed to the two letters on the above subject which appeared on page 406. No hint of this possibility being given in the pamphlet containing the plans of the proposed hall circulated among the members of the Royal Horticultural Society, the inference to be drawn is that the decision of the council is final. That the plans do not meet with general approval is evident. Your leading article of the 22nd ult. voiced what I venture to think is a widely-spread feeling of disappointment. A leader in one of your most influential contemporaries of the horticultural press has contained a reference to "the mean appearance of the exterior," and has pointed out the desirability of "simplicity of design, harmony, and beauty of proportion," while numerous letters of protest have been published in the columns of other gardening papers. A country member, resident at a distance from London, of necessity lacks the opportunities that occur to those living in the metropolis of frequent meetings with other members and of thereby ascertaining their views, but those whom I have met or have been in correspondence with are, almost without exception, dissatisfied with the appearance of the proposed building.

There is, I am persuaded, no wish on the part of members that money should be spent in ambitious and costly ornamentation, but there is, I think, a desire, as there rightly should be, that the building to be erected may by its simple dignity of design stand as a worthy memento for generations yet unborn of the society that is recognised by the world as representing all that is best in British horticulture. It is affirmed by some who are well qualified to express an opinion that such a building might be erected for practically the same expenditure as that requisite if the present plans are adhered to. Most members will, I imagine, coincide with the views of "A Fellow of the R.H.S.", published in your issue of the 13th inst., that it would have been advisable to have thrown the design for the hall open to public competition. If this is now done, presuming that the council are not absolutely committed to the design submitted to the members, it would doubtless, as your correspondent suggests, mean a certain outlay before a decision was arrived at, but it might well prove cheaper in the long run.

Members would be inclined to subscribe far more freely to the hall fund if the design were one that earned their commendation than if

it were one they disapproved of, and from the list of subscribers published in the pamphlet containing the plans of the proposed hall there are still over 5,600 members who have yet to make up their minds as to the extent of their donations. That all may eventually subscribe something to the hall fund, whatever the council's final decision may be, is my earnest hope, but there is no doubt in my mind that the augmentation or lessening of the donations will largely depend upon the design.

The matter of internal arrangements and accommodation, on which subject there has already been a certain amount of correspondence, I leave to those who are most closely interested in it. I have penned this letter not in any cavilling spirit, but with the sole desire, as a member of the Royal Horticultural Society, that the centenary of that body may be marked by the erection of a hall that Englishmen may be proud of and that foreigners may view with respect. That the present design fails to fulfil these conditions many beside the writer are convinced.

S. W. FITZHERBERT.

## NOTES OF THE WEEK.

**Royal Horticultural Society.**—The first meeting of the committees of the above society in 1903 will be held as usual in the Drill Hall, Buckingham Gate, Westminster, on Tuesday, January 13. An election of new Fellows will take place at three o'clock. To prevent misunderstanding it may be mentioned that the committees of 1902 do not vacate office until the date of the annual meeting, 1903, and, in like manner, all Fellows' tickets of 1902 are available until the end of January, 1903. At a general meeting held on Tuesday, the 9th inst., fifty-one new Fellows were elected, making a total of 1,140 elected since the beginning of the present year.

**Lindenbergia grandiflora at Kew.** In several of the houses at Kew this plant has been flowering since early October, and now in December there are still many flowers and buds. This long flowering period, together with the fact that the flowers are borne throughout the dullest months of the year, should commend it to all those who have to keep a conservatory gay during winter. It is said to be common about the foot-hills of the Himalaya from Simla to Bhutan at an elevation of from 2,000 feet to 6,000 feet, and it is also found in Pegu and further east. It is a sub-scendent herbaceous herb, reminding one of a Salvia when not in bloom. The flowers are yellow, and in shape like those of the common Musk, but are much larger, being about three-quarters of an inch in length and half an inch across the mouth. It can be grown in much the same way as Salvia splendens, and is very serviceable in 6-inch pots for winter flowering from cuttings rooted in heat in spring.—W. DALLIMORE.

**Vinca acutiloba.**—This is a perfect mass of bloom now; in fact, it is never out of flower, and is a capital plant for running up through the foliage of Irish Yews, where its pretty white flowers are most effective. *V. elegantissima variegata* has the same striking appearance running through Golden Yews, both spreading and upright varieties.—W. BAYLOR HARTLAND, *Ardfearn, Cork*.

**Sutton's New Year Savoy** is very valuable as a winter vegetable, and is certainly well named, as with us in the North (Northumberland) it remained good till the spring, and was of great value on that account. It is one of our best and latest winter vegetables. The Savoy is more frequently grown for early autumn supplies, and grown thus it is not as useful, as at that season there is a wealth of green produce. I am aware that some kinds are none too hardy, but on that account I think this variety should find a place, as it has not so far been injured by severe weather. This variety has a short leg or stem, and being

close to the soil is not so much exposed to the wind. Another point often overlooked in the case of winter Savoys is that it is not desirable to sow seed in spring too early, as frequently the plants thus sown are left too long in the seed-bed. I would advise early May sowings and early planting for late winter supplies. Grown thus, the plants turn in during the late autumn and keep sound till spring. The flavour of the Savoy from now till March is much milder than in early autumn, and this is a strong point to be considered in vegetable culture.—G. WYTHES.

**Apple Norfolk Beauty.**—When last year Mr. W. Allan, of Gunton Park, exhibited fruits of his fine new Apple Norfolk Beauty, the date of the meeting of the fruit committee at the Drill Hall was October 15. The variety then obtained an award of merit. It was then stated that the fruits keep longer than Warner's King, one of its parents, that fine and far too much neglected variety and good keeper Waltham Abbey Seedling being the other. This season, to show that the Apple is a good keeper, Mr. Allan sent up a bushel of fine fruit on the 9th inst., just eight weeks later, and the quality of the flesh showed that the fruits would be good for a month longer. Such fairly enduring quality makes this fine Apple a most useful addition to our stock of winter cooking Apples, and the flesh of the fruits when baked is delicious indeed, nothing could be pleasanter. Not a few of these fruits have that russetty coating on their skins found on Waltham Abbey Seedling. In the Royal Horticultural Society's Journal of April last are portraits of the variety, one showing fairly conical fruits, the other flatter, like Warner's King. The semi-conical form generally characterised the fruits recently shown. The award of a first-class certificate was unanimous.—A. D.

**Two good Chrysanthemums for the garden.**—Most lovers of these will agree with me that some varieties are better for this purpose than others. It is practically useless to attempt to grow the large Japanese kinds in the open late, except in a few very favoured positions or in warm localities. But this is not so with the two kinds I am about to name. The first is Mary Anderson. This is considered the best single white variety. The flowers are not as large as some, but this does not interfere with their decorative value. It should be grown by everyone who has a garden, both under glass and in the open. We have grown them thus for many years, and for the open garden at the foot of a warm wall it is excellent. Grown in this way we cut this year a quantity of flowers with long stems through November and till severe frost in early December. The autumn being so mild it was not unusual to see Chrysanthemums, Salvias, Clematises, Dahlias, &c., in bloom at the same time. Julia Lagravere has been quite as beautiful as the variety Mary Anderson. Though a very old kind, I can remember it forty years ago being grown in pots with Cedo Nulli, Christine, &c. Few at the present time can equal it in the open garden. Its best and brightest colour is seen in the open. Few things are handsomer at the foot of a light-coloured stone wall during the last two months in the year. For years I grew it in a big mass on a border, and protected it with some lights, removing them by day. In this way splendid material was obtained for cutting at a very small cost. Should anyone be induced to try these two in the open, and need a third one, then try Source d'Or, still a grand bronze. These three grown together are excellent.—J. Crook.

**Parrotia persica.**—I can testify to the perfect hardiness of this plant, having planted a few some twenty-five years ago. I was not particular as to soil or situation, but had them located next to *Phellodendron amurense* to get a bit of bright colouring; it stood the winter of 1879-1880, when we had on several occasions temperatures of 9° Fahr., and the soil frozen to 3 feet, and one of them is now a good tree, 6 metres to 7 metres high. The colouring also much depends on changeable weather, alternate sunshine and rain.—MAX LEICHTLIN, *Baden-Baden*.

I was much interested in Mr. Burrell's account

or note of this lovely scarlet and gold-tinted tree or shrub. I have four splendid specimens in conspicuous positions, where the sun shines on them the entire day. And this autumn, though not so rich in colour as usual, they were noticed by many visitors. I have scarcely ever noticed it in nursery lists. The specimens referred to here are 6 feet to 8 feet high. Some of them are layered for stock. It is a glorious bush in September and October, and the effect is much improved by running *Vinca elegantissima variegata* with bronze or black leaved Ivy through its branches.—W. BAYLOR HARTLAND, *Ardfearn, Cork*.

## THE FLOWER GARDEN.

### POLYGONUMS BY WATERSIDE.

**A** PRETTY way of planting the well-known *P. sachalinense* is shown in the accompanying illustration, i.e., in a simple spreading group, with the bold handsome leaves and stems reflected in the clear water of the stream. The plants were photographed when in flower, and at that time the *Polygonum* is at its best, the small tassel-like creamy blooms hanging, so to say, in abundance from the wiry stems. *P. sachalinense* is bigger altogether than *P. cuspidatum*, which I regard as a troublesome but beautiful weed. It springs up everywhere, even in a gravel path. The compactum variety is less unruly, but is without the free grace of the species.

VIATOR.

### TROPAEOLUM SPECIOSUM.

I SHOULD most strongly advise "Sproughton Hoe" to purchase well-established roots of this creeper in pots and to plant them out about the middle of March. Though no mention is made as to the nature of the soil in which it is proposed to plant, it may prove helpful to your correspondent if I give my own method of treatment on the light sandy soil of this garden. In order to ensure success a position should be chosen where the soil is always loose and moist and the atmosphere cool, and where the direct rays of the sun cannot fall upon the plant. This latter point is of the greatest importance. Many years ago we obtained some plants from Kelso, planting some of them against a north wall sheltered by a Yew. Numerous cases of failure with this creeper have come under my notice, and in one or two instances I found that the roots had been placed either in a soil that baked quite hard or else in a badly drained position where the soil had become sour. In my own case the soil consisted solely of very poor sand and gravel, and in preparing the ground only the top spit was retained, the remainder being taken away to the depth of 3 feet.

I then mixed the soil which was left with about four parts of fairly light loam, two of leaf-mould, one of peat, and one of wood ashes. After the plants had got well established I gave them several applications of weak liquid manure during the summer with most beneficial results, and this practice I have since continued. Each succeeding year the plants gain in strength and beauty, and now occupy a large area of wall which we have covered with wire netting for them to cling to. I have never had occasion to sow the seeds, of which we have a crop every year; but I notice that the birds have done this for us, as it has made its appearance in the vegetable garden, and, worst of all, in the rock garden, where its presence was certainly not desired. In planting pots of established roots care should be taken not to plant them too close to one another as they spread very quickly. It is certainly a curious plant to manage, as even when given good soil and a suitable position it is not by any means certain to establish itself. When it does get a start the shoots seem to come up in all sorts of places,

sometimes everywhere except just in the position chosen for them and where most required.

When the young growths appear in spring care must be taken to protect them from slugs. The weakest shoots should be thinned out, as it is more satisfactory to have a few good strong ones rather than a tangle of weakly trails. As regards position, a north one is not at all essential to success; in fact, a west one appears to suit it quite as well. On the whole I rather favour the west wall here, because the streamers receive more sunshine, and for this reason no doubt they bloom better than those in the dense shade of the Yew. I have propagated this plant successfully in April by carefully forked up a piece of the peculiar white tuberous root with a young growth attached and transferring it immediately to its required position. It should, however, be borne in mind that this is a plant which resents disturbance, and, as previously advised, the best and most satisfactory plan is to purchase some well-established pots of this subject. It is certainly well worth all the care and trouble required to establish it, and for draping a wall or

down to a small straw, and if these are planted and covered with about 4 inches of soil they will push forth shoots from nearly every joint. T.

If "Sproughton Hoe" has to deal with a hot, dry soil, where *Tropaeolum speciosum* does not "do" well, he will find the following a sure way to succeed. This *Tropaeolum* is propagated by tubers, and a healthy plant produces a great number. They are not unlike *Alstroemeria* roots. If small, twelve can be bought for 1s., well established roots being about 6s. for twelve. Wrap the tuber in living sphagnum moss, then pot it in a mixture of two-thirds sandy peat and one-third leaf-mould in pots from 4 inches to 6 inches across. It is not too late now, though late October is better. Keep in a cold frame till spring, then start them with sun-heat by placing under a south wall and keeping them moist. When the growths are a few inches high plant in a good pit of sandy peat, leaf-mould, and firm loam, but do not disturb the ball. They look best among Roses or small-leaved wall shrubs. I have them growing on a north-east wall. Some

beauty," but when two to three years old they are both ornamental and useful. At any rate they are no expense or trouble to grow.

Dawlish, South Devon.

A. BAYLDON.

## SOUTH AFRICAN FRUIT CULTURE.

(Continued from page 311.)

### CONVICT LABOUR.

In dealing with the important subject of agriculture at the Cape, one cannot pass over the most important movement initiated by Mr. Eustace Pillans, of utilising convict labour on the Government establishments in the Peninsular. The result has been most satisfactory and encouraging. Little supervision is required as no attempts are made to escape. So convinced do the convicts (mostly coloured men) become of the value to them of learning

how to acquire some skill in working, that they have been known to commit petty crimes in order to be taken in again after they have served their time. In March last there was a large bush fire on the slopes of Table Mountain, only too common by incendiary, and 200 were sent to stamp it out. They had ten officers with them; the night was very dark, yet they all returned after the fire was out without the slightest hesitation. Many acquire considerable skill on the Vine farm, and can get good wages subsequently. Whether English convicts can be utilised on farms in a similar way may be doubtful, but the severest punishment which the Cape convicts dread is to be sent back on the harbour and other works as navvies.

The following is extracted from Mr. Pillans' "Reports."

In alluding in his Report of the Department of Agriculture for 1895, Mr. Eustace Pillans, the agricultural assistant, after speaking of the difficulty in obtaining labour, through the constant drain of "hands" to Kimberley, Johannesburg, and Cape Town, writes as follows:—

"A few years ago it was suggested that a way out of the *impasse* might be found by the utilisation of convict labour upon private farms. Naturally the Convict Department, with whom rested the responsibility, hesitated before committing themselves to a hitherto untried experiment, the success of which was dubious, and the failure, through the least slip of detail in management, might be attended with very serious consequences. It is greatly to the honour of the chiefs that after mature consideration they put aside routine and made the trial. The system has been in force for two years, a sufficient time to enable a judgment to be formed upon its merits. It must be remembered that the material forming these gangs consisted almost invariably of natives from the eastern and midland provinces, stock

thieves and men who had done no work all their lives but herding cattle. They had to be taught the most primary notions as to the use of tools, and get over their natural disinclination to take to labour which their instincts had taught them to consider to be woman's work.

"At the present moment the verdict of all the farmers who have had the service is decidedly in its favour. The men are proving themselves teachable, good-tempered, and orderly, and are fully aware of the personal

POLYGONUM SACHALINENSE BY WATERSIDE.

festooning a tree or shrub it is the loveliest of all our hardy creepers.

Worcestershire.

ARTHUR R. GOODWIN.

THE roots are not bulbs but thick thread-like thongs. They should be planted about 7 inches deep, the tubers being laid horizontally in a mixture of sand, stable manure, loam, and leaf soil, as they will not grow in clay. Plant in a north aspect. The first year they will probably not grow very tall, but about the third year flowers may be expected. They die down in winter. They will grow in a peaty soil.

M. A. P.

IN answer to your correspondent "Sproughton Hoe" in THE GARDEN of the 13th inst., there is no difficulty whatever in propagating *Tropaeolum speciosum*, the principal point being in some districts to induce it to grow, while in others it gives no trouble whatever. It does not produce bulbs, but forms a great quantity of thickened underground stems, the stoutest of which is not very much thicker than an ordinary lead pencil. If an established mass is dug up these underground stems will be found from the size just mentioned

small tubers so treated last autumn flowered well this summer, though I must say they did not do so well as established plants put in at the same time; those made 10 feet growths. The only trouble with this plant is to get it to begin to grow. After the first year there is no trouble. My newly planted ones fruited well, though it was not a good season this year. There is no need to buy Palm seed. When the next box of Golden Dates comes to table keep the stones (seeds). We have a lot of two year and three year old Palms from such seeds. Make earth as it would be for a Vine border, loam and old cow manure; half fill one of the cast iron troughs that are used to give moisture to a hothouse. They are some 15 inches long, with concave bottoms, to fit on to one of the hot-water pipes. Place this on the hottest pipe, adding warm water till it is wet mud, in which plant the Palm seeds, keeping the soil quite wet all the time. They only take a few weeks to start, though some may be much longer. Pot into usual Palm compost, but I fear that "Sproughton Hoe" will be very disappointed at the result of his venture if he wants an ornamental yearling Palm, as the two or three leaves are only like grass. Later on comes a leaf with two divisions, decidedly not "a thing of

advantage which they are gaining by being told off for labour in field and vineyard, in place of the monotonous and far more exhaustive toil of the Breakwater quarry. The proof of this lies in the fact that in no one instance has there been a case of desertion or attempted desertion from any of the gangs located on private farms. The only cases on record are those of two or three new arrivals deserting from the Government farm itself, before they had got to understand the motives which prevented the older hands from evasion.

"There is more involved in this experiment than appears upon the surface. The reflective politician, whose aim is the improvement of administrative method rather than the ins-and-outs of party, has ever found the hardness of the task of converting the population of the gaols into law-abiding, wage-earning subjects. It is not contended that the Constantia experience in the Government vineyards has been upon a large scale, or that its conditions are applicable everywhere; still it is undeniable that native pastoral loafers to the number of nearly 300 are being converted into good, useful farm-labourers; and the unexpected part of it is that many of these do not return to their original pastoral nomad life, but actually hire themselves out to farmers of their own districts on the strength of the knowledge and deftness they have acquired. They evince some little pride in what they have learned, and even take offence if set down as 'raw Kaffirs.' 'Nou is ons volk, en kau gelt verdien.' This would seem exactly the spirit to encourage, and it will be a new element for good, and a makeweight upon the reformatory side of prison discipline.

"Independent of the benevolent philanthropic side of this interesting matter, there is the inevitable monetary side, and the conditions of cost, one is happy to say, work out all in favour of the extension of the system wherever local conditions prevail.

"The farmer who receives the convict service gladly pays all expenses, so much towards the pay of the constable in charge, and provides the necessary approved housing. Consequently the Convict Department has a distinct economic interest in forwarding the movement, besides the consciousness that they are at the same time providing a remedy for the worst difficulty the farmer has to contend against, and doing something to bridge over the gulf between the irresponsible native pastoral mode of life and the next higher agricultural stage."

Since the year in which the preceding was written (1893) convicts are employed all about the colony. Besides the Government Vine farm at Groot Constantia and the Forests at Tokai, many farmers are employing them, having about ten men on the average a piece. I asked Mr. Pillans as to the statistics of the number that reverted to their old ways. His reply was he had none, as all had been reclaimed. After the time expires they always hire themselves out.

I here add an extract from the *Cape Times* of March 10, 1902, which may be interesting to those who wish to know something of this excellent system.

#### AGRICULTURE AND LABOUR.

With regard to this subject Mr. Eustace Pillans, of the Government Agricultural Department, calls attention in his Reports of 1899-1900 to the common prejudices, with their resulting *vis inertiae* against manual labour by "white" people. It is also urged upon him by many that the conditions obtaining in Cape Colony are so different from those in England that it is useless to make any

changes towards supposed improvements, when suggested by the Government Department, until, in the course of years, success and a business profit can be proved to come of it. Such observations strike one as on a par with those maintained by parents who would forbid a boy to enter the water until he could swim!

On the other hand, Mr. Pillans is of opinion that practically there is very little difference indeed between many of the most important conditions of the agricultural industry in South Africa and those which prevail elsewhere. Just as English labourers persist now in going to the towns and leaving the farms, so do they in South Africa go to Johannesburg for the diamond and gold industries, and crowd into the coast ports.

How to check this wastage and establish a thriving rural population at the Cape is the great question of the day. A primary difficulty in Cape Colony is that there are no Crown lands to dispose of to intended agricultural immigrants. All land is under proprietors, and they cannot be bought out. The crux, therefore, is to dot this colony all over with an industrious well-to-do population of small farmers.

Mr. Pillans has also sound remarks to make as to the supplying a would-be settler with information. He says that the Government must establish an active business-like emigration agency for the Cape personally familiar with every detail. At present the London Agency is limited to ordinary business and has little to do with the requirements of emigrants. This has been done most admirably by the colonies of Australia, New Zealand, and Canada.

"It were a pity, indeed," he observes, "if the Cape could not follow their example and find the very best possible man to do her bidding and crown her wishes in the matter by successful performance."

But there is another question, and that is how to reorganise the labour market? What is wanted is new blood in the cultivating classes. In the first place, as stated, colonial-born youths drift away into the towns. On the other hand, the Cape Government has established schools of agriculture, as at Elsenburgh, but the number that attend is much smaller than might do so.

"We have, as a people, to get rid of the idea that the average country-bred youth is 'too good' for the land, that he must look out for a 'profession' or he will sink in the social scale." It is the unfortunate but mistaken public opinion which prevails, that labour is derogatory for a white man, and that it is beneath him to [literally] put his hand to the plough, and so, as it were, compete with the coloured races.

That the reader may understand something of the complicated state of the labour market, I here subjoin a letter to the *Cape Times* in reply to one in which it was suggested that Chinese should be allowed to compete with the natives. It is as well for an intending emigrant to know beforehand something of this question, for numerous enquiries are being constantly made, indeed almost daily, of Mr. Pillans, at the Agricultural Department of the Cape Government, especially as to the facilities offered to young men who wish to farm in this colony. It is too soon to speak of what openings there may be in the Orange River Colony and in the Transvaal.

Now the first and most essential advice to be given is that, however well trained he may be in English farming, he must pocket his conceit and be willing to learn what agriculture is at the Cape. Then his former experience

will, doubtless, greatly assist him and prove suggestive in improving methods of culture as carried on in the Cape Colony.

It must be remembered, as already stated, that there is *no land* at the disposal of the Cape Government as in newly-acquired countries; but many farmers have already and others are willing to receive young men to work on their farms on various advantageous terms, provided they prove themselves capable men. In some cases they give their labour for a certain time in return for board and lodging, or they receive a piece of land to cultivate or on which to raise stock for their own profit, &c.

Another important item is that the young man must *set his face against the popular prejudice about working with his own hands*. As a practical result some hundred young men are now at work on farms and doing well.

G. HENSLOW.

#### DIERAMA (SPARAXIS) PULCHERRIMUM.

The Dieramas, a small tribe of remarkably graceful Irises from South Africa, will interest everyone who has a warm dry border in which to grow them. The old name, Sparaxis, is still in general use, but owing to the marked disparity between Sparaxis proper and Dierama in form, habit, hardihood, and garden value, it is necessary to recognise the tall, arching, bell-flowered plants as Dieramas and the dwarf starry-flowered plants as Sparaxis proper.

There is only one species recognised by the majority of botanists, *D. pulcherrimum*, a tall-growing plant, some 4 feet high, with very tough, yet slender and arching, grass-like leaves, and still taller racemes of delicate pendulous flowers, which sway and tremble with every breath of wind. The colour in the accepted type is purplish crimson, the flowers measuring  $1\frac{1}{2}$  inches to 2 inches in length and 1 inch in span, averaging from ten to twenty in each raceme. The bulb, which resembles that of *Gladiolus*, is covered with a thick matted tunic, and the roots are thick and evidently capable of resisting great drought, a character revealed in all parts of the plant. The variety *albium*, a lovely white-flowered form, is the rarest and choicest of the group. Its flowers are not a pure white, the claw-like petal lips and the base of the flowers are rose-tinted.

*PENDULUM*.—A paler rosy purple form, and does not differ very much from the type, though often called a distinct species. Its leaves are more rigid, the spikes shorter, and the pedicels are a little longer than in typical *pulcherrimum*, whilst the flowers are more closely arranged on the pedicels, the weight of which gives the inflorescence a more pendulous habit than that of the type.

*ATROPURPUREUM*, another good variety, has dark purple and more widely distended flowers, but it is not so beautiful as the lighter coloured forms. Another variety, of which I have only seen a few flowering examples, is coloured a pale flesh-pink, with rosy tips and base, a really delightful plant, but very scarce and difficult to obtain. It has no distinctive name so far as I am aware, and is probably a chance seedling.

*CULTIVATION*.—Their cultivation is a simple matter. They may be planted in the open in a light warm soil without screen or protection; but in wet clay soils, in the colder parts of the North and the Midlands, the shelter of a wall is necessary, primarily to ripen their bulbs well, so they do not start into growth too early; and, secondly, to give shelter to the young growths, which often pierce the ground before they can make headway. Seedling plants are easy to raise in light soils, and mature bulbs increase fast when well established. One needs a clump of ten to twenty bulbs to see the plants at their best. The best clumps I have seen were growing in deep loam overlying limestone.

G. B. MALLETT.

## CHRISTMAS FRUITS.

(Continued from page 424.)

### THE ALMOND.

THOUGH belonging to the Nut tribe rather than the fruit, being the seed of a closely allied species of *Prunus* (*P. Amygdalus*), the Almond may be referred to here as an addition to the Christmas dessert, as it is nearly always closely associated with Muscats. The tree needs no description, as it is such a favourite in our gardens and shrubberies on account of its early flowers, these being followed in some favoured localities by the fruits perfecting their seeds, which are the Almonds of commerce. Two distinct varieties of Almonds are known in trade—the sweet and the bitter: the former is the dessert Almond, and is also largely used in confectionery. The finest quality is known as Jordan, and comes from Malaga in Spain. This name is supposed to have been derived from *jardin* or garden, referring to its produce by cultivation as no Almonds come from the country of the Jordan.

### BITTER ALMONDS

come from Mogador and Barbary. Both kinds yield a large proportion of oil, but the "essential oil of bitter Almonds" is obtained from the bitter variety, and is poisonous, from the presence of prussic acid. An essence prepared from it is much used in confectionery and perfumery. The quality of Almonds in this year's market is said to be good though the crops have been small.

Oranges, Lemons, Kumquats, and the various other fruits produced by species and varieties of the genus *Citrus* we need only refer to, as they are in some form or another always with us, though more so at this season than at any other. The

### THE ORANGE TRADE

by extended culture, both in old and new countries, the extremely prolific character of the plants in fruit bearing, and many other interesting facts come to our minds as our eyes rest on the golden fruits in the shops at the present time. Moreover, if we have botanical inclinations we can let our minds wander amongst genera other than *Citrus* of the same tribe *Aurantiae* and the same natural order *Rutaceae* to discover many other interesting fruits unknown to British trade.

It is a long run from the *Rutaceae* to the *Urticaceae*, a large group of plants of varied character, ranging from the common Elm down to the Stinging Nettle, but it is in one section of this order, namely, the *Moreae*, that we find

### THE FIG (*FICUS CARICA*)

which, though a native of Syria, Persia, Asia Minor, and perhaps South-Eastern Europe and Northern Africa, has long been grown in the regions of the Mediterranean, as well as in warm and sheltered situations in the South of England, where it ripens its so-called fruits, which, as most people are now aware, are not really fruits, but a hollow fleshy receptacle, containing the flowers inside. It is not until this receptacle has become fully ripe, at which period the viscid juice is changed into sugar, that the so-called fruit is edible. In Smyrna and other Fig-growing countries the fruits are either allowed to ripen on the trees or are gathered and dried in the sun. Formerly they were packed in circular boxes or "drums," but most of the Figs—except the poorest qualities, which are sometimes packed in bags—now come in neatly-made oblong boxes of varying sizes and weights. The Fig is a good wholesome article of food, having slight aperient properties, and though it is generally seen as a dessert fruit at Christmas, at other seasons of the year there seems to be but little demand for it.

The foregoing are a selected few of the principal fruits prominently before us at this season of the year. They represent only four natural orders, all of which belong to the dicotyledonous group; but there is still another fruit which claims attention, not only because it is considered a necessary dessert fruit at Christmas, but also by reason of its historical associations. I allude to

### THE DATE,

which, as every one knows, is the fruit of the Palm (*Phoenix dactylifera*), a tree attaining a height of 100 feet to 120 feet, ranging from India, through Western Asia, Egypt, and North Africa. In early times the Date Palm was abundant in Palestine, and formed then, as it does now, one of the most important food-producing plants of the people. It is generally supposed to be the Palm tree referred to in the Bible. From Egyptian and Assyrian remains it seems evident that the Date tree was known and valued by the ancient peoples

of those nations, and at the present time in Egypt and Arabia the fruits are very important as an article of food, both for human consumption as well as for cattle. A very large number of varieties of the Date are known, some of which produce fruits formed of little else but the stone, covered with a thin skin, and therefore quite unfit for human consumption. The varieties which yield the fine plump fleshy Dates of our shops are, of course, the most esteemed. They contain about half their weight of sugar. These fruits, as most people know, are borne in large spadices or clusters, averaging about 20lb. in weight. The market supplies this year seem to be both abundant and good, Persian Dates being quoted as low as 1½d. per lb. A large quantity of the English supply comes from the countries on the African coast of the Mediterranean.

The Date Palm has been long introduced into the South of Europe, where, although it grows freely, it does not ripen its fruit, except under the most favourable conditions, as in the South of Spain. The leaves, however, are tied up and blanched, and form a large article of trade for decorative purposes, especially for use in the Anglican and Roman Church on Palm Sunday.

## THE ROCK GARDEN.

### ROCK GARDEN-MAKING.

#### IV.—PRACTICAL HINTS ON ROCK BUILDING WITH STONES OF THE UNSTRATIFIED CLASS.

**I**N the last chapter on rock gardening (see *THE GARDEN* of November 29, pages 378 and 379) I discussed the question of which stone to use, and explained the great difference between igneous rocks and sedimentary rocks. I will now proceed to deal with the first of these two classes in a more practical way, with suggestions how to use the igneous rocks in the construction of rock gardens, and by an actual illustration of my own method of dealing with such rocks, giving a series of photographs all taken during the same week, but during different stages of the work.

It has already been stated that igneous rocks, like granite, are not found in successive layers or strata, but occur naturally in the most varying forms. Sometimes they form dense masses, at other times they are loosely scattered in large or small groups, or even as single boulders loose on the ground or cropping up from the surface. In some instances they bear evidence of secondary upheavals and appear tumbled over each other in the wildest disorder, thus forming large or small caves or deep fissures. Where single stones crop up from the surface it will almost invariably be noticed that the green sward around such a stone appears raised, even if the ground generally should be more or less flat. This is evidence of upheaval from below, and on examination we generally find that such apparently single stones are really only the top of huge masses of rock below the surface. In imitating Nature, when building rocks with stones of the igneous type, it should therefore be our aim to group these rocks as irregularly as possible, and where we put single stones we should raise the ground around them so as to give greater probability to the idea of natural rock having pierced the surface in such a way that only the top is visible, while the bulk is hidden below ground. Such imitations of natural rock are not obtrusive but suggestive, and are often more natural and therefore more pleasing in their effect than artificial structures of a much bolder kind.

I.—A WEEDY BANK SITE FOR A SMALL ROCK GARDEN (FIRST DAY).

When discussing the subject of sites for a rock garden in THE GARDEN of October 25, pages 286 and 287, I gave two illustrations showing the site of a rock garden, and the same site twelve months later when the rocks had been completed. This rock garden was on a large scale, and in its construction I used not less than one thousand tons of stone. There are only few gardens, of course, which would be suitable for a rock garden on such a scale, but by way of contrast I will now illustrate the actual construction of a rock garden within one week only.

#### A ROCK GARDEN IN A WEEK.

Being engaged in the construction of a small rock garden in North Cornwall a little more than a month ago I embraced that opportunity of photographing the work during its progress, not with a view of showing my own work as a pattern, but because an example from actual practical work conveys more than many pages of essays and theories. The accompanying four illustrations were prepared from those photographs. There was an interval of only five days between taking the first and the last photograph, and the transformation from the weedy bank represented in the first picture to the finished work shown in the fourth picture was therefore really effected in a trifle less than a week. The material used was about twenty-five tons of granite, gathered on a moor, thus having an ancient appearance and being partly covered with moss and lichen. Picture No. 2 shows the preparatory work. Weeds on the bank were cleared off and everything made irregular by excavating about ten or twelve loads of soil in the middle. The reason for this is obvious. Granite cannot make an effective rock garden unless it is arranged quite irregularly. The excavation shown in the picture is really larger than required, so that where the stones are in position a sufficient quantity of soil might be filled in behind the stones to allow small shrubs, alpine plants, &c., to flourish.

Illustration No. 3 shows the principal stones

placed in position. It will be observed that they are irregularly grouped, rather massive in the centre, and more scattered towards the end of the little rock garden. Due attention has been paid to the fact that boldness is increased or emphasised by having a projection or promontory immediately adjoining a recess. The recess in the picture appears deeper in reality than is shown by the illustration, which gives the ground foreshortened and apparently flatter than it really is. The bottom of this recess has been fitted with stepping-stones and filled with peat. It is intended for a bog bed for hardy Cypripediums, Houstonia, &c.

The fourth picture shows the completed work. On comparing it with the third picture it will be found that only a few stones have been added. Some of the small stones were driven in above and below such plants as were put in sideways. Where two or more large stones join each other the hollow space between them is filled with soil, and the crevices on the outside are filled with plants which in less than six months will obliterate all traces of a joint and the work will then look like solid rock. To some extent, it will be observed, this has already been obtained, and picture No. 4 looks more natural than picture No. 3, but after a single season's growth the effect will be far more striking.

Elmside, Exeter.

F. W. MEYER.

#### NOTES FROM SWANSWICK.

##### MISTAKES IN A RECENT GARDENING BOOK FOR CHILDREN.

In some of the books about gardening that appear in such steady streams there are many mistakes in names which grate horribly on the ear of even a moderately practised gardener averagely accurate. A certain recent book addressed to children, but written in a grown-up way which suggests an appeal to their elders is especially and astonishingly defective in this respect. One might put up with slip-

shod writing and terribly ungrammatical sentences, but it is rather too bad of any author to "set up" to write a gardening book in a tone of authority, and misspell one plant name in ten! If people who really do not know very much about their subject, otherwise than in theory, *must* deliver their dicta, the employment of a proof-reader who is a practical gardener and owns to a little Latin might be advantageously made compulsory. Of course scholars sniff at gardeners' Latin, and still more at gardeners' Greek, and more especially when the two are morganatically allied, but such as our garden nomenclature is, it has its own and quite arbitrary orthography, and must be taken or—in these cases preferably—left. "Printer's errors" occur, of course, and are annoying enough, and publishers are not always grateful to their authors for lavishly corrected proofs, but the author cannot shift all his duty to his public on other shoulders and go blameless. I lost sympathy with the author of the interesting

##### "TUSCAN GARDEN"

when she recorded the evasion of her garden on a certain day when some particularly interesting Chrysanthemum cuttings had arrived from England, and the consequent vexation of their suffering because they had to wait—whether three days or longer is not quite clear—to be potted. Such a task is so easy and so pleasant she might surely have done it herself without any waiting at all; a *real* gardener would, I think, have flown to it. However, carping aside, the "Tuscan Garden" is recalled to me because we have been planting some *Prunus Pisardi*, and in this book there is an interesting note about it which altered the destiny of one of the trees. First planted as a shrubbery background, to set off *Prunus triloba* in front, one of the batch has been promoted to a sunny position in the best part of the fruit garden, because the author of the Italian memorabilia (this is late or Dog Latin, and, therefore, a more appropriate word than the classically correct "memorabilia" for use on garden occasion) says that its fruit is very delicious, and it is, therefore, being extensively grown in Tuscany. Possibly it is known here, but, like the writer, I have only heard of the tree as an ornament, and should like information on this point. A belated argument against too much "massing" which has just occurred to me is suggested by our difficulties in deciding where the "masses" we have—in some cases—dutifully planned are to go. For example, in planting *Anemone fulgens* who can say whether it will like the site chosen for it? It is, of course, a lovely thing made much more lovely by being planted in quantity, but as it is quite impossible to say that it will succeed in any particular situation, and as it is hardly cheap enough for very extended experiment, and ground is very much too precious for the same, are we not morally compelled to dot it about in trial patches? Eventually, no doubt, all these can be conglomerated, but in the meanwhile separated group planting seems inevitable. Even in gardens whose every foot of soil is known in all its characteristics to the owner some quite trifling change of position may make all the difference to a plant: how much more is this the case where the soil differences are as yet an unconquered book to a new comer.

Among willing plants *Arabis alpina* fl.-pl. certainly takes a high place. It seems not only able but eager to grow anywhere and under any conditions. Some very small bits, broken off by accident, and thrust loosely into the ground in November, have, I see, rooted and spread to thrifty little plants already,

2.—THE SITE CLEARED AND PREPARED FOR ROCK BUILDING (SECOND DAY).

while the legitimately planted clumps run rampant in all directions. It does not seem to be in accordance with the usual order of events that the very superior scion of a race should so far outstrip the original type in vigour as well as in beauty.

A correspondent of *THE GARDEN* asks where Palm seeds can be procured, and her question answers itself in the same issue, for the desired seeds are therein advertised to be sold by auction. Vast is the number of Palms themselves that auctioneers yearly offer, and presumably sell at prices remunerative to the growers. Since the average non-gardening buyer of room plants must take most of these over from retail florists it appears that a terrible slaughter of the innocents must be always proceeding.

M. L. W.

## CHRYSANTHEMUMS.

### CHANGES IN THE METHODS OF EXHIBITING LARGE BLOOMS.

**R**EERENCE is frequently made by contributors to *THE GARDEN* of the need for altering the present system of exhibiting large exhibition blooms. A change of methods in showing large blooms has, however, been carried out in some degree, unconsciously, perhaps, to many in several instances, and keen observers will not have attended the National Chrysanthemum Society's meetings and exhibitions of some of the leading provincial Chrysanthemum societies without having seen evidence of the desire for a more satisfactory way of exhibiting the larger blooms. Those who have the best interests of the flower at heart know well how monotonous a continuous array of blooms set up on show-boards becomes to a casual visitor.

The National Chrysanthemum Society has for some years encouraged a change from orthodox ways. Classes in which some of the best blooms in the show are displayed in vases are increasing in number, and appear to have quite eclipsed what were at one time regarded as the great events to win, notably the forty-eight Japanese, and the twenty-four Japanese, too. The great vase class at the Royal Aquarium show, which has always been set out in the cooler quarters of St. Stephen's Hall, has, since its institution, always proved a success. There are also several other classes in which the large blooms, usually to the number of six, have to be set up in a single vase, and arranged in such a way that they face all round alike. In the earlier days the six white or six yellow Japanese blooms, as the case may be, were arranged on the ordinary show-boards, and the greatest difficulty was experienced in displaying them without the petals of one bloom interlacing with those of its neighbour on the same board. What is the case now? The individual beauty of each bloom is seen, and the arrangement is generally good.

There were also at the National Chrysanthemum Society's November exhibition classes for incurved blooms, to be set up in vases, and a very welcome change they were to the exhibits on show-boards. The incurved blooms never looked better, and their splendid depth was better seen than when "cupped up" on the show-boards. The Anemones in some cases were also exhibited in the same way, but the small number of exhibits was regrettable. For some reason the money prizes in the classes for these quaint flowers are not liberal. This may possibly account for the poorness of the display. There is room for improvement in this respect in all classes, and those who desire to make their exhibitions even more popular than many of them are to-day, and who also wish to revive the flagging interest of some of the less fortunate ones, should give this matter careful attention. No one type should receive too large a share of the prize money. Although singles, both large and small

3.—THE PRINCIPAL STONES PLACED IN POSITION (THIRD AND FOURTH DAY).

flowered, are displayed in dwarf earthenware vases—and this is a distinct advance upon the show-boards used at one time—there is room for improvement. Taller vases and a more liberal supply of flowers should be asked for. Three vases, each with twelve blooms daintily adjusted, would look immeasurably better than the six vases of six blooms in each, arranged as they are at present with mechanical regularity. Better still would it be to see three vases, arranged as a decorative exhibit, in which the exhibitor should be required to use a given number of varieties at least. This would have the effect of illustrating their decorative value.

The same remarks apply with equal force to the Pompons and Pompon Anemones. These charming flowers when partially disbudded, and free-flowering sprays requisitioned, are capable of creating an effect of which few persons are aware. The use of vases in which to display the different types of the Chrysanthemum should have the effect of completely transforming the appearance of the shows, and this would also serve to break up the long and even lines and flatness which have characterised Chrysanthemum shows since they first became popular. Each year the change would be more noticeable, as the newer introductions would give novelty to the display. The December show of the National Chrysanthemum Society as an exhibition was far more interesting than most of its kind, owing chiefly to the fact that vases of blooms largely predominated. Each vase of flowers had something in it to please, and there was nothing monotonous about them. The splendid exhibition of the Highgate Chrysanthemum Society in the unrivalled Central Hall of the Alexandra Palace, in the early days of the Chrysanthemum season, was an object-lesson of what could be done with large blooms in vases, as well as others of a decorative kind.

D. B. CRANE.

## GLEANINGS FROM RECENT BOOKS.

### NATIVE TREES AND SHRUBS IN WINTER.

RAMBLING about the country in winter one becomes more and more impressed with the beauty of our native evergreen trees and shrubs. Seven names comprise them all—Yew, Holly, Scotch

Fir, Spruce, Juniper, Box, and Ivy. Even of these the Scotch and Spruce Firs (commonly so-called, though the Scotch is a Pine) are doubtful natives, though so long acclimatised that they may be classed with our own. Those who are laying out new grounds on a large scale would do well to plant these grand things in plenty; indeed, in the case of any new planting that is taken in hand, unless the owner has a good knowledge of shrubs and some taste in their choice and disposition, a planting of these alone would save him from many a regrettable mistake and from the prospect of the usual senseless jumble of mixed shrubbery that has hopelessly spoilt thousands of gardens.

No foreign shrubs can compare with or take the place of our Yews and Hollies. However large a collection of exotics may be in a well-stocked arboretum, a winter walk among them only shows that there is nothing more cheerfully handsome than our Hollies or more solemnly dignified than our Yews. On dry, sandy soils no conifer is better for England than the Scotch Fir, or for moist, loamy regions and valley bottoms none is better than the Spruce. Exception is sometimes taken to the Spruce, and when planted in other than the place it likes it is, indeed, a wretched object, as on dry and hilly grounds. But a mass of common Spruces in a cool alluvial bottom is a picture of well-being, and no one can deny their majesty on alpine hillsides. The Douglas Fir is sometimes recommended in their stead, but this beautiful and quick-growing tree must still be regarded as an experiment. There is not, as yet, a single old Douglas Fir, and there are some among our botanical experts who are yet in doubt whether, for all its young vigour, it will be a lasting tree for our country.

Then for dry uplands in light soils there is the lovely Juniper, best of all its kind (though often in nurseries foreign ones only are offered to its exclusion), and for chalky soils and loams the Box luxuriates and can be used as a small tree as well as in its usual bush form. The use of common Ivy should not be forgotten. How important it is in winter may be perceived by anyone during a country drive, when it will be seen to be the one most conspicuous living thing, adapting itself to a diversity of use that is quite extraordinary.—*Trees and Shrubs for English Gardens.*

## TREES AND SHRUBS.

### THE HOLLY AND SOME OF ITS VARIETIES.

**C**OMMON Holly is one of the most useful of our hardy evergreens, and, as THE GARDEN has pointed out on several occasions, is not planted so much as it might be.

This neglect, however, is partly due to the fact that it is of slow growth, and is also a fairly expensive plant to buy, especially when it has attained any size. The Holly is a native of Britain, Europe, and the western parts of Asia. It is often found in this country growing in the middle of woods, where its dark shining foliage forms a strong contrast to the deciduous trees or Scotch Pines surrounding it; but although a native plant, and one that should be easy to deal with under cultivation, it is one of the most difficult to transplant. In raising it from seed the berries should be gathered in early winter, mixed with sand, and put in a heap covered with turf until spring. About the middle or end of April they should be sown in a prepared bed out of doors, and covered with about half an inch of fine soil. A small proportion will germinate the first year, but the main crop will not appear till the second season, and if the bed is left the third year will see a fair sprinkling of belated stragglers above ground. The work, however, with Hollies has only begun when the seedlings are above ground, as upon the attention they receive during the next three or four years their future welfare depends. The seedlings should be planted on good ground, with a fair sprinkling of manure, and be moved annually in the autumn for the next three seasons at least, when they will retain some soil about the roots and will stand two years without removal. They will then be only about 18 inches to 2 feet in height, and their growth afterwards—unless they are

permanently planted—will be nearly, or quite, as slow, so that a good Holly, 10 feet high, that will bear removal without dying is the product of many years' growth, and also means that much time and labour have been expended in transplanting it.

#### SELECTION.

There are nearly a hundred named varieties of the Holly, but many of them are more curious than beautiful, while some of the others are so much alike that the numbers are greatly reduced when we come to really distinct forms. A good selection comprises the following:—

#### VARIETIES WITH SILVER VARIEGATION.

*Silver Milkmaid Holly* (*argentea medio-picta*).—This is a handsome plant when it is kept true; but unless carefully watched and the strange growths cut away it is apt to go green. The leaf is like that of the common Holly in size, shape, and spines, and the white variegation is confined to the centre leaf, the edges being of a bright shining green.

*Silver Queen Holly* (*argentea regina*).—This has a rounded, rather flattened, spiny leaf, with a deep border of silver, changing to creamy white in winter. The wood is purplish red, and the plant has a close and compact habit.

*Handsworth Silver Holly* (*handsworthensis*).—This is the best all-round silver variegated Holly, being bold and striking in colour, and of an upright and vigorous habit. The leaf resembles that of the common Holly, and the variegation is confined to a broad stripe around the edge, the centre being of a dark shining green.

#### VARIETIES WITH GOLDEN VARIEGATION.

*Aurea angustifolia*.—This is an upright, quick-growing variety, with narrow spinous leaves, which are narrowly bordered with gold. It makes a handsome pyramidal plant in a comparatively short time.

*Gold Milkmaid Holly* (*aurea medio-picta*).—This is similar to the Silver Milkmaid, except

that the variegation is bright yellow instead of white.

*Golden Queen Holly* (*aurea regina*).—This is by far the brightest of the variegated Hollies, but it is, unfortunately, of slow growth, and takes many years to form a really good plant. The leaf has usually a broad margin of clear golden-yellow, but sometimes the variegation is in large splashes of colour, and occasionally whole leaves and branches will be found entirely yellow.

*Moonlight Holly* (*flavescens*).—This is a very handsome plant when well coloured, the leaves having a pale yellow tint exactly resembling a plant seen by moonlight. It is of good habit, and a fairly rapid grower.

*Golden King Holly* (*aurea rex*).—This is a comparatively new form, but one that will be popular when it becomes better known. It is a plant of bold and vigorous habit, and from present appearances will make a handsome tree. The leaves are large and broad, mostly entire, or with few spines, and have a broad edging of clear golden-yellow, with a centre of dark shining green. A distinct and good Holly.

*Waterer's Gold Holly* (*watereriana*).—For standards or low bushes for formal gardens this Holly cannot be beaten, as it is of a close, compact habit, and requires little attention to keep it in shape. The leaves are oval in shape, ending in a short spine. The margins are entire and broadly edged with gold.

#### GREEN-LEAVED VARIETIES.

*Balcarica*.—This is an upright, quick grower, with very dark green shining leaves, mostly entire, but occasionally with a few spines on the upper half of the leaf, which is also wavy in outline. It berries well in most seasons, and the bright red fruits are shown to advantage by the dark foliage and the open habit of the plant.

*Camelliaefolia* (*daurifolia*).—This is a Holly that is worthy of more attention than it receives, as it is a bold and striking plant, especially as a large specimen. The leaves are from 2 inches to 4 inches long, entire, or with but few spines, dark green, and shining as if varnished. The plant is a good grower, of rather thin habit in a young state, but filling out well with age.

*Hedgehog Holly* (*ferox*).—This probably shows as much variation from the type as any Holly. The leaves, which are rather small, have, in addition to the spines on the edges, a covering of short spines on the upper side, which character is well illustrated by the common name. It is of slow growth, and takes a considerable time to form a specimen of any size. There are two variegated forms of this, viz., var. f. *argentea*, with white variegation, and var. f. *aurea*, coloured with yellow.

*Yellow-berried Holly* (*fructu luteo*).—This only differs from the type in the bright yellow of its fruits and the lighter colour of the wood and leaves. It is also a more rapid and upright grower, and berries well.

*Hodginsii*.—Next to the common Holly this has probably the largest sale of any, and its popularity is well deserved, as it is handsome, of good habit, and fairly quick growth. The leaves are large and broad, armed with stout spines, and of a dark shining green. As a hedge plant it is equal to any plant grown.

*Scotch Holly* (*scotica*).—This is a slow growing bushy form with ovate, leathery leaves, which are wavy and spineless, and thickened along the edges. It makes a splendid bush plant of medium height.

*Wilsoni*.—This is a comparatively new plant, of vigorous habit, with large, flat,

4.—THE ROCK GARDEN PLANTED AND FINISHED (FIFTH AND SIXTH DAY). (See page 441.)

rugose leaves edged with straight spines. It makes a handsome pyramidal bush with age, and has large crimson berries.

#### WEEPING HOLLIES.

*Perry's Weeping Holly* (*argentea pendula*).—This is a good pendulous form with typical leaves edged with silver. It is of slow growth, and requires time to form a really good specimen.

*Waterer's Gold Weeping Holly* (*aurea pendula*).—This resembles the former, except that the variegation is golden instead of silver and the leaves are somewhat smaller.

*Pendula*.—This is a green-leaved weeping form, and makes a handsome plant of its class when well grown. It is of fairly rapid growth and makes a good specimen with very little attention.

All the Hollies require a certain amount of attention in the way of pruning, especially when young, as they are apt to grow bushy and broad instead of going upwards. August is the best time for pruning, as a short growth is made before winter, which keeps them from looking bare.

The common Holly is best propagated from seed, and the varieties can be raised by budding or grafting, or by means of cuttings and layers. The latter is the best method, except in the case of standards, which are budded on stocks of the type during summer or early autumn. The Weeping Hollies should be worked 8 feet or 10 feet high to be effective.

*Bugshot, Surrey.*

## ROSE GARDEN.

### ROSE FLORA.

**O**f the Cluster Roses, so-called from the flowers appearing in clusters or bunches, Flora is one of the sweetest; its colour is a clear pink, and, as the illustration suggests, it blooms abundantly. It is strong in growth, and just the Rose for the corner of a pergola such as shown in the illustration. I was charmed with the article on pergolas you published a few weeks ago—I mean Miss Jekyll's contribution. I have read it with profit and pleasure.

VIATOR.

[The article referred to appeared in THE GARDEN of November 8 and 15.—ED.]

### HARDINESS OF ROSES.

#### VARIETIES FOR COLD CLIMATES.

A CORRESPONDENT from Sweden wishes to know which of the good garden Roses are likely to be the hardiest. He does not say for what part of Sweden they are wanted, and his post town does not appear on ordinary maps; neither does he state his extreme winter temperature nor length of winter. We should advise him to try the following:—Rugosas and their hybrids, Scotch Briars and *R. altaica*,

Sweet Briar and Penzance hybrids, Boursaults and *R. rubrifolia*, *Rosa alba* and vars., *R. lucida* and the double kind, *R. macrantha*, *R. Andersoni*, Carmine Pillar, Leuchtstern, Eleanor Berkeley, Rubin, Psyche, Dawn, Una, Pomifera, *R. humilis* and hybrids, Moss and Provence Roses, Hybrid Chinas, such as Mme. Plantier, Vivid, &c., and the Ayrshires and other climbers derived from *R. sempervirens* and *R. arvensis*.

Perhaps some of our correspondents in the cold Midlands and the worst climates of Scotland could add to our list Roses found to be hardy in rather severe districts.

CLIMBING ROSE FLORA OVER POLE.

### WINTER PROTECTION TO ROSES.

I suppose giving to tender Tea Roses the sort of protection that you say Mr. Mawley gives his standard Teas in Herts, and which you have so forcibly, though not picturesquely, illustrated, is not only useful so far as these Roses are concerned, but is the right thing to do. But what a penalty has to be paid for the summer pleasure of having standard Teas in one's garden by making them, to ensure protection from frost, such hideous objects as are those depicted on page 410. I like Roses as well as the most enthusiastic rosarian, but I could not tolerate the existence of such depressing and ungainly things as thatched heads of standard Teas in my garden. One is tempted to ask if such form of protection be needful. Why grow standard Teas at all, at least in any open or conspicuous part of

a garden? If they are essential why not plant them in some enclosed garden kept solely for such objects, into the close recesses of which no stranger's eye could penetrate during the winter months. In the case of dwarfs all experience seems to have proved that their best protector in hard weather is soil, and such covering up as may be needful to keep the wood from injury by frost offends no one. If standard Roses must be had, and not all Rose lovers care for them, at least is it not better to grow as such good hardy Hybrid Perpetuals or other hardy varieties than tender ones like so many Teas that will not endure the sharp frosts of our winters, without being made into scarecrows, especially when following on a dull, cool summer. Of course I may be told that what does not offend the vision of such a cultured lover of Roses and of high art in horticulture as Mr. Edward Mawley should not offend mine. That may be or may not be so, but after all how many readers of THE GARDEN are there who can honestly say they would like to have in their gardens winter-thatched standard Roses?

A. DEAN.

## INDOOR GARDEN.

### GREENHOUSE ACACIAS.

**M**ANY of the Acacias suitable for greenhouse culture are excellent indoor flowering plants, for they are easily grown, require little fire-heat, and flower profusely either planted out in borders or when growing in pots. Upwards of 400 species are known, and of these about one-fourth are in cultivation at Kew. Of these species some eight or ten are often met with in gardens, but numerous others rarely seen are quite as worthy of culture. The genus is widely distributed through Australia and parts of Asia, Africa, and America, by far the greater number and the most useful from a horticultural point of view being found in Australia. As might be expected in such a large genus a great diversity of form exists, some species making large timber trees, others low bushes not more than 1 foot or 2 feet high, with all sorts of intermediate stages. The Australian species as a rule have stems without spines, so differing from many of the species from other countries which are armed with very formidable spines, ranging from half an inch or so long in some species to the long horn-like spines of the American *A. Hindsii* and *A. spadicigera*, the latter being commonly known as the Bull's Horn

Acacia. Many of the Australian species have no true leaves, the leaves being reduced to mere scales, while the petioles are enlarged and fulfil all the functions of such; these enlarged petioles are known as phyllodes. This character must not, however, be looked for in all the Australian species, for in some cases true leaves are borne, and in others both leaves and phyllodes; the best example of the latter case is *A. melanoxylon*.

The flowers of the Australian species are of various shades of yellow, in one or two cases being almost white. They are borne either in small fluffy balls, short racemes, or large panicles, and the time of flowering is from October to May.

The uses to which Acacias can be put are many and varied. As pot plants they are decidedly ornamental and are essential to the furnishing of a conservatory in spring, while for planting out in

large houses they are indispensable. When grown in the latter way the generous treatment is productive of more growth and flowers.

The usefulness of Australian Acacias for furnishing large houses is well shown at Kew, where one of the principal features of the winter garden is made by these plants, there being many huge specimens which flower well annually. The soil most suitable for Acacias is a mixture of loam and peat into which plenty of sand has been mixed. It is essential that the drainage both for pot and border plants should be perfect, as they dislike stagnant water about the roots. After flowering the plants should be well cut back, and the house kept close and moist until young shoots appear. Repotting should then be done, and as soon as new roots are formed abundance of light and air must be given till the flowering season approaches, when a little more warmth may be given with advantage. As Acacias much dislike any disturbance at the roots, when planting out is contemplated take care to place the plants at once in the positions they are to occupy permanently.

The habit of each species suggests the method of culture to adopt. Some are seen at their best when grown as trees, others as bushes, and others again which make long scendent growths are never seen to greater advantage than when supported by a pillar. The temperature necessary for Acacias depends on the time they are wanted in flower. If they are to bloom naturally they merely require a house from which frost is excluded, but if they are wanted in flower for midwinter a minimum of 45° should be given. Pot plants will winter very well in a frame with a cool ash bottom, and are improved by being plunged outdoors in summer. Propagation is by seeds and cuttings. When seeds are to be sown they should be soaked in boiling water for a few minutes previous to sowing; this will assist germination. Cuttings of young shoots 3 inches long root readily in summer. Insects do not trouble Acacias very much, thrip being the worst enemy, and this may be kept down by fumigating.

Of the numerous cultivated species, the following are the most useful from a horticultural point of view:—

*A. acinacea*.—This is a slender and graceful plant, from 4 feet to 6 feet high, bearing small linear phyllodes three-quarters of an inch long, and numerous small round fluffy balls of yellow flowers. It flowers naturally in March.

*A. armata*.—This was introduced about a century ago, and is probably the one most commonly met with in gardens, being grown largely in some places for market. Its principal characteristics are a dense bushy habit, obliquely ovate, spiny dark green phyllodes, and good-sized round heads of fragrant golden flowers. The varieties *angustifolia* and *undulata* are worth growing, particularly the former. It is excellent when planted in a border, shoots 3 feet to 4 feet long being made annually, which early in April are wreathed with blossoms. The habit of the plant is semi-pendulous, the phyllodes long and narrow. In addition to being good border plants, all the three are excellent for pot culture.

*A. baileyana*.—This is one of the newer species, and has not been in cultivation many years. From its habit of growth it appears as if it will make a tree. It produces true leaves, which are of a lovely glaucous hue and bipinnate. It blooms when young, the flowers being in small, globose heads arranged in short racemes. The colour is golden.

*A. celastrifolia*.—Though this is not one of the strongest growers, it makes a shapely bush and flowers freely. The phyllodes are from 1½ inches to 2 inches long, and the flowers, which are pale yellow, are in short axillary racemes. It is very distinct from most species, but is considered by some a synonym of *A. myrtifolia*. The two are certainly much alike, but whilst the flowers of the former are yellow those of the latter are almost white.

*A. cultriformis*.—The curious knife-shaped glaucous phyllodes of this are quite distinct from those of other species. It was introduced from New South Wales about eighty years ago, and is fairly popular in gardens. The flowers are golden-

yellow and borne freely in round heads. Though it will grow upwards of 12 feet high, it is more often a quarter that height.

*A. dealbata*.—For a large winter garden this is excellent. To see it at its best it must be planted in good soil and have room to develop a good-sized head. It is popularly called the Silver Wattle on account of its glaucous leaves. The flowers are borne in winter and early spring. They are fragrant, yellow, and produced in small round balls, which are again arranged in large panicles. For a small house it is not suitable, as it is only when it has attained a large size that it is seen to advantage.

*A. drummondii*.—This is a very free flowering dwarf species, bearing bipinnate leaves and lemon-coloured flowers in short, drooping racemes; it makes an excellent pot plant, and is also suitable for border culture.

*A. hastulata*.—The thin wiry stems and small three-cornered, sharp-pointed leaves stamp this as distinct from anything else. Long shoots are made annually, along which the small cream-coloured flowers are borne profusely.

*A. leprosa*.—No better subject than this can be obtained for clothing a tall pillar where the long slender branches can hang in a graceful and natural way. The whole plant is light and elegant, the phyllodes being 5 inches or 6 inches long, very narrow, and bright green. The flowers are bright yellow, and freely borne along the whole of last year's shoots in globose heads. March and April are the months in which it may be expected to flower. Though seen at its best against a pillar, it is also useful as a pot plant.

*A. lineata*.—This is very ornamental by reason of its long narrow phyllodes, which are profusely borne, and give the plant a very pretty appearance. The flowers are cream-coloured and appear throughout autumn and winter.

*A. longifolia*.—This has strong upright growths, leafy phyllodes 3 inches to 6 inches long, and a quarter of an inch to one-third of an inch wide, and numerous upright racemes 2 inches to 3 inches long of yellow flowers borne from the axils of the leaves along the whole of the previous year's growth. This species grows at least 15 feet high and quickly forms a large bush. Several varieties are known, of which *floribunda* and *magnifica* are worth growing; both are freer than the type.

*A. myrtifolia*.—In general appearance this is much like *A. celastrifolia*, but the flowers are almost white.

*A. obliqua*.—For pots this is excellent, making a shapely bush of graceful outline and flowering with great freedom. It rarely grows more than 2½ feet high; the phyllodes are small, scarcely a quarter of an inch across, and flat. The flowers are in small round heads, and borne from the leaf axils. It is also known as *A. ovata*.

*A. platyptera*.—The winged branches of this make it distinct from other species. In some places it is grown for market, but does not seem so popular as are several others. It seems to like a little more heat than most Acacias, and also more peat in the soil. At Kew a fine plant 6 feet high is growing in a border of sandy peat in the greenhouse and appears to be quite at home. The flowers are deep yellow and appear in midwinter. At Kew a plant similar in habit, but with white flowers, flowered last year.

*A. pubescens*.—This species has a tree-like habit, bipinnate leaves, and small heads of primrose-scented blossoms produced in racemes from the axils of the year old shoots. It is increased by root cuttings, and should only be severely pruned every other year.

*A. pulchella*.—Market growers have long favoured this species, and it is well known by reason of its small bipinnate leaves, globose heads of golden blossoms, and somewhat spiny shoots. At Kew it grows quite 20 feet high and flowers very freely.

*A. riceana*.—Like the preceding, this is a popular plant with market growers. It makes a lovely specimen grown either in pots or borders, the habit being pendulous and the phyllodes small. The flower heads are small and in large drooping

racemes, the colour of the flowers being cream. When planted out it should be supported by a rough post on which side branches a foot long have been left.

*A. urophylla*.—This is one of the earliest to flower, being usually at its best about Christmas. It is of elegant outline, and has pendulous branches. The phyllodes are broadly ovate, the flowers almost white, and in round heads. It flowers very freely, and deserves to become popular.

*A. verniciflora*.—Seeds of this were first sent to Kew about 1823, though it had been discovered in 1817 by Mr. Allen Cunningham. It is a small grower of elegant habit, with small phyllodes and large quantities of golden flowers. It is worth a place in any garden, being good alike as a pot or border plant.

*A. verticillata*.—Visitors to Kew during March and April have a good opportunity of judging of the value of this species, for there are several fine specimens in the Temperate house which flower magnificently every year. Branches 6 feet or 7 feet long are made annually. These are clothed with small, dark green, sharp-pointed phyllodes, which in the flowering season are almost hidden by small cylindrical racemes of fragrant yellow blossoms. Though it flowers well as a pot plant it is best seen when forming bushes 12 feet to 15 feet high and 8 feet to 10 feet through.

W. DALLMORE.

## THE KITCHEN GARDEN

### GARDEN PEAS.

RECORDS of the Pea trials at Chiswick—and for the past three years they have been exceptionally extensive and good ones—make interesting study. Still, they offer chief interest to those privileged to examine them from time to time, as members of the fruit and vegetable committee and the Royal Horticultural Society's officials do. Whilst various awards are made—and properly made, too—to some old varieties, the merits of which have in the past not received adequate notice, the growing of these enables the committee to note with fair and full comparison how far novelties or new varieties do present advance over those of preceding years. Last summer, with a very fine trial, only three first-class certificates were awarded, and these to varieties some time in commerce, viz., Daisy, Senator, and The Gladstone. All were found in first-class condition and with high-class reputations. In the preceding year (1901) the only first-class certificate awarded was to Prizewinner, then a remarkably fine cropping variety, and the preceding year only two first-class certificates were granted, these being to Edwin Beckett, a new variety, and to Alderman, the finest probably of all the tall section. First-class certificates are awarded now only to varieties that stand out from the general body of others as being exceptionally good, and with so many assumed new varieties in the trial, it was interesting to find that the three getting these awards last year were well known established ones. That leads to the very natural assumption that raisers have in general excellence in cropping, fine pods, productiveness, and flavour nearly reached the end of their tether. Edwin Beckett was the only Pea which secured the first-class certificate whilst still an unknown variety during the past three years. Even Prizewinner so fine in 1901 was known in commerce. My selection of six medium height garden Peas hard to beat are Gradus, Senator, Peerless, Edwin Beckett, Prizewinner, and The Gladstone. If all be sown together they cover a good period of time, but no one, except for trial, would do that. A. D.

### VEGETABLES IN SEASON.

WITH the approach of severe weather choice vegetables will become scarcer. At this season those that give a distinct change will be welcomed, and as these are mostly grown with little trouble they should not be lost sight of.

## ASPARAGUS.

This vegetable is forced so readily that very little advice is required unless it be to amateurs, and to them, unless there are proper structures and good material, forcing Asparagus is costly. Often an old bed that has seen its best days may with advantage be lifted and placed in heat and brought on slowly; indeed, hard forcing should not be attempted. A temperature of 60° is ample, but from 15° to 20° higher temperature may be allowed should there be no rapid rise, as at this date the roots soon respond to gentle forcing. I have referred to beds being lifted. This only applies to certain gardens, but roots are now specially grown by the trade and these force readily. In our own case we use a large proportion of fresh leaves in preference to large bodies of rank manure. The moist leaves suit the roots admirably. Of course all forced Asparagus at this early date is from glass structures, but even now we are busy preparing our permanent beds for cutting early in the year, and from these beds a much larger supply is maintained than from lifted roots, and the quality is excellent.

## SEAKALE.

The old but excellent system of forcing this vegetable in its growing quarters had much to commend it — though the labour entailed was greater, the quality was better. Kale forced in moist leaves or under pots is, in my estimation, far better than that forced in a Mushroom house or under stages in a drier atmosphere. I am aware that in these days, when rapid growth and larger quantities are needed, different ways have to be thought of. Still, in a private garden it should be remembered that flavour should be considered. The market garden system of placing lifted roots in trenches and forcing with treated manures gives good Kale, as the roots never suffer from dryness and the produce is very tender and succulent.

## CHICORY AS A VEGETABLE.

Many may not agree with me in placing this root as in season at this date, but it is, and a valuable one also if properly cooked. We well know that Chicory is of great value as a salad plant, but its value as a vegetable must not be forgotten.

Cultivation is simple; indeed, only very slow forcing is needed, and the edible portion consists of the young growths about 4 inches to 6 inches long just before they expand. When the roots are placed in the dark, such as in a Mushroom house, about every fortnight they will produce a regular supply, and as these are so readily grown from seed sown in the spring there will be no difficulty in keeping up a supply through the winter months. For use as a vegetable the Witloof is the strongest grower. This has a compact growth, that when cooked and served with melted butter closely resembles Seakale; the common or ordinary kind is not suitable for this purpose, consisting of thin poor growths. The Witloof and similar varieties are much used on the Continent as a vegetable.

## CELERY.

This is a most valuable winter vegetable when stewed, and in many gardens Celery could with advantage be grown specially for this purpose. Of course a white variety is most suitable, and I prefer a short thick grower. Many persons prefer Celery to Seakale, and when well served it is delicious.

## CUCUMBERS.

Until recently Cucumbers have been plentiful, and in some gardens they are grown all the year

round. I would advise their use as a vegetable, as they are agreeable when nicely served. For this purpose we grow the short kinds, such as Syon House or Sutton's Every Day Cucumber. The latter is valuable in winter.

## CELERIAC.

This is quite as good as Seakale when served as a vegetable, and being a bulbous root it needs more cooking. In Germany it is a great favourite in winter; being of sweet and nutty flavour, it is much liked, and splendid roots are grown. The plants should be grown from seed sown early in the spring, and it does not need trenches like Celery, but likes a rich soil. To get large roots give plenty of moisture, and in winter lift and store them in a cool place or in a well-drained soil. The roots winter well if covered with litter in severe weather.

## SALSIFY AND SCORZONERA.

are the most valuable winter vegetables in season now. When Salsify is well grown it is worth a place as a leading winter vegetable, being preferable I think to Scorzonera. From now to March or later it adds to the list of vegetables. The roots should be lifted and stored in a cool but frost-proof shed, as if wintered in heavy soil they

## ORCHIDS.

ORCHIDS AT ROSSLYN,  
STAMFORD HILL.

**W**ELL KNOWN in horticultural circles is the name of Mr. H. T. Pitt, of the above residence. His frequent exhibits at the Royal Horticultural Society are always worthy of close attention, and the beauty, variety, and excellent culture of the plants shown may be taken as applying to the whole collection, as a recent visit to Rosslyn conclusively proved.

Though this part of London is certainly one of the most favoured with regard to climate, yet fog, smoke, &c., are very troublesome; but that an enthusiastic lover of Orchids, as Mr. Pitt, and a keen, careful observer, such as his Orchid grower, Mr. Thurgood, can overcome these difficulties is fully proved by the condition of the plants. Among the many other good things open at the present time the following are particularly worthy of note.

STAR PRIMULAS AT MESSRS. SUTTON AND SON'S, READING.

decay after severe weather. There are other roots, such as the Artichoke, that give variety. The small Chinese variety is delicious when well served. The new Sutton's White is a splendid addition; it can be cooked in various ways.

G. WYTHES.

## STAR PRIMULAS AT READING.

VERY shortly our greenhouses and conservatories will be bright with winter and early spring flowers, and amongst them the Star Primulas will find an honoured place. Messrs. Sutton and Sons, Reading, have effected a great improvement in these flowers, having produced more vigorous plants, blooms of splendid form and substance, and, above all, they have widely extended the range of colour in the Star Primulas. In early spring a house filled with these plants in flower in Messrs. Sutton's nurseries at Reading is worth going a long journey to see; some idea of their free flowering may be had from our illustration, representing one of Messrs. Sutton's houses.

## THE ODONTOGLOSSUMS.—O. HALLII CRISPUM.

The parentage of this Orchid is indicated by the name, and commands attention from its singular beauty and character. The influence of O. Hallii is plainly discernible in the flower, particularly in the decided toothing of the petals and the beautiful fringe around the lip, but, except that the sepals are slightly narrower than in a good O. crispum, the general contour of the flower is like that of the last-named species. The colouring, however, is widely different. The sepals are a clear deep canary yellow, slightly attenuated at the apices, and bearing five and six nearly confluent blotches of ruddy cinnamon. The tips of the petals are reflexed and their colour is soft canary yellow, shading to white at the centre and base. A dash of deep red-brown runs at right angles to the column base, and about twenty small spots of the same colour are aggregated centrally. The lip is very broad, with the well-defined basal shoulders of O. Hallii and a forked crest, the tips arranged in convolute fringed folds. The whole is in varying shades of light yellow,

except a few scattered red blotches, largest and deepest in colour midway between the tip and crest.

A fine plant of the rare natural hybrid duvivieriæ was just opening its flowers on a well-developed spike. The parents are presumed to be apterum (nebulosum) and maculatum. Unfortunately it has been seldom imported and is exceedingly scarce, though its shapely white and chocolate blotted flowers are very beautiful. A beautiful form of Pescatorei with finely shaped flowers, round in outline and thick in substance, also attracted notice. The flowers, broadly speaking, are white, but not pure white. Though entirely without spotting, throughout each flower runs a dainty tinge of rose-lilac, very faint, but distinct enough to make the variety even more beautiful than if it had been quite white.

#### ODONTOGLOSSUM LOOCHRISTIENSE VAR.

A handsome form of this beautiful hybrid between O. crispum and triumphans was also in bloom, the stout spike and substantial flowers showing the advantages of good culture. The sepals and petals have a ground colour of clear yellow, shading on the margins to deep gold, the petals being much lighter than the sepals centrally. Each sepal bears two bars of confluent chocolate-red blotches, while the sepals bear four rounded but unequal spots on the apical halves. The labellum is placed on the column in the same manner as the triumphans parent; it is light yellow basally and on the crest, shading to white on the margins. On the apical area are one large and two small red blotches. The collection of Odontoglossums at Rosslyn is very rare and extensive, and much more might be said of them, as indeed of all the other sections here only just alluded to. Among

#### CYPRIPEDIUMS,

of which a very representative selection has been brought together, was a light coloured form of C. macrochilum, a hybrid between C. longifolium and C. caudatum Lindenii: it is very striking as seen here, and the long ribbon-like creamy white and rose shaded petals are charming. In this variety the dorsal sepal is almost entirely creamy white, with only a slight tinge of rose and green. The lip is marked with warm olive brown on a white cream shaded ground colour.

Two fine specimens of C. leeanum giganteum were observed with magnificently developed flowers, the finest the writer ever remembers to have seen. This variety still remains among the best forms of leeanum, and judging by these two specimens it is unlikely to lose its position.

A beautiful collection of Cypripedium insigne was in bloom, including two striking unnamed forms. One resembled C. insigne var. Dulcetense, but was far finer, and the other has very dark markings, reminding one of the finest varieties of the grand hybrid M. de Caste. A surprising feature of the collection is the Phalaenopsis. London and its environments are the last places in which we expect to find these beautiful moth Orchids growing well, but here, suspended from the roof of a small house, they luxuriate, and from their clean healthy look are apparently proof against even London fogs. The plants are now full of flower-spikes in course of development, and should shortly give a splendid effect.

In another warm house was noticed the original Dendrobium Phalaenopsis of Fitzgerald in bloom, together with its pretty ally D. bigibbum. A distinct form of Forbes's D. Phalaenopsis schröderianum was also flowering; it has quite white sepals and petals

in strong contrast to a deep rose-purple labellum.

In addition to the better known and more showy Orchids, Mr. Pitt is greatly interested in the seldom seen and so-called botanical Orchids. A plant of the very rare Cirrho-petalum appendiculatum was in bloom with large curious insect-like flowers. This species differs from the majority composing the genus, as the flowers are solitary and not carried in umbels. The lower sepals are drawn out to a length of 6 inches or 8 inches, while the sepals and petals each bear a wonderful fringe-like plume, that on the dorsal sepal being the largest. The prevailing colours are purple and white. The once common but now rarely seen Coelogyne barbata was also in flower, the snowy sepals and petals and black-brown hairy lips of the flowers being very conspicuous.

Mr. Pitt is a genuine amateur, loving his flowers for their own sake, apart from their rarity, but a plant must have some good points to find a place in his collection. ARGUTUS.

#### CATTLEYA MAGNEANA.

This splendid novelty is one of the most brilliant of the genus. It was obtained by crossing Cattleya guttata Leopoldii (a superior form) with C. massaiana, one of the most beautiful of the hardyana group. The leaves, some 20 centimètres long by 7 centimètres broad, are thick and tough, and of a beautiful deep green colour. The flowers, which open well, are of remarkable size; the greatest attested diameter is, indeed, 9½ centimetres. The sepals are firm, and the upper one is remarkably erect. They are of a clear ruby colour. The petals are very large, waved on the edges, and of an intensely deep ruby colour. The labellum, which is of perfect form, very large and well formed, with broad undulations, is of an intense ruby colour, deeper on the undulations. A pale tawny reflection tints the interior of the throat as well as its reverse side. The cultivation of this plant does not demand any particular care; it will thrive with the other Cattleyas in a house with moderate temperature.

CH. MARON, in *Le Jardin*

### GARDENING OF THE WEEK.

#### THE FRUIT GARDEN.

##### THE EARLY PEACH HOUSE.

No attempt must be made to hasten unduly the development of the flower buds, as this would weaken them and prevent a good set of fruit, and as soon as they commence to unfold the spraying of the trees should be discontinued and a comparatively dry atmosphere maintained, though in fine weather the floors of the house should be damped early in the afternoon. At this stage keep a night temperature not exceeding 50°, and cause a movement of the air both night and day by keeping the top and front ventilators more or less opened in accord with the conditions of the weather. The day temperature should be maintained at 55° in dull weather, but allowed to reach from 60° to 65° from sun warmth.

##### EARLY VINERIES.

Houses containing vines that are bursting into growth should have a night temperature varying from 55° to 60°, the higher degree being upheld in mild weather with a corresponding day rise, slight ventilation being given when the temperature assisted by the sun's warmth reaches 70°. As the growth, which makes quick progress at this stage, proceeds attend early and diligently to disbudding by removing the weakest shoots first, and completing the operation once it can be discerned which are possessed of the best bunches. Well thin the laterals so that enough only are

left to clothe the trellises with foliage without crowding.

##### MELONS.

Seeds for the first crop should now, or at an early date, be sown in 2½-inch pots. Use fine moist soil, plunge the pots in a hotbed, and cover them with a sheet of glass. No water will then be required until the seed has germinated, when the plant should be kept near the glass of a structure possessed of a night temperature of from 65° to 70°, with the usual rise by day. Preserve a moist atmosphere by syringing the plants in the morning and early afternoon of fine days, and as soon as the pots are well filled with roots plant them 2½ feet apart upon narrow ridges or hillocks of warm soil composed of turf loam, moderately mixed with crushed mortar rubble, leaf soil, and soot.

##### QUEEN PINEAPPLES.

In order to secure a supply of ripe fruit in June, the plants rested for the purpose, as previously advised, should be started without delay. The night temperature of the house should accordingly be raised to 65°, to be shortly further increased to 70°, with a corresponding day rise, the house being slightly ventilated when the temperature reaches 80° from sun-heat, and at such times spray the plants with tepid soft water when the house is closed. The temperature of the plunging material should likewise be raised to about 85°. Slightly increase the atmospheric moisture, give the plants sufficient tepid water to moisten their soil thoroughly, and subsequently examine them weekly, and water those requiring moisture with tepid weak gnano water. Keep the glass of the structure perfectly clean, and remove early suckers as they appear.

T. COOMBER.

#### INDOOR GARDEN.

##### BEGONIA SOCOTRANA.

BEGONIAS are charming winter-flowering plants; as they bloom nearly all winter and spring they deserve to be grown to a much greater extent than they have hitherto been. Many of these Begonias are not only remarkable for their free flowering, but also for their dwarf habit and easy culture. They delight in an intermediate temperature, all the light possible, and a tolerably moist atmosphere. Less water at the roots must be given at this season, and the plants should not be syringed overhead. Plants in bloom may be kept in a house whose temperature is 50°. The Rex section of Begonias, where quantities are required for covering walls in ferneries or for growing under stages, may be propagated by means of the leaves. Leaf cuttings may be conveniently rooted in shallow boxes filled with sharp sand or cocoanut fibre and placed in a propagating case. Well matured leaves should be selected, and with a sharp knife cut across the larger nerves on the under side. Then they should be laid upon the sand or fibre, using a few pieces of potsherds to keep them down. Plants Begonia Gloire de Lorraine, when past flowering, should have less water given them; let it be done gradually, but do not cut down until the tops show signs of decay, and then they are better if shortened back. These may be readily struck from leaves dibbled in with about an inch of the stem in cocoanut fibre and shading from sunshine till rooted.

##### FORCING HOUSE.

To keep up the supply of flowering plants—Narcissi, Tulips, Hyacinths, Lilliums, and other bulbs, also such plants as Azaleas, Deutzias, and Staphyleas—they should be brought into gentle warmth. Sudden changes of temperature are fatal to forced plants, so they should never be taken direct to the cold conservatory or house.

##### COLEUS THYSOIDÆUS.

This winter-flowering Coleus is a great acquisition to our winter-flowering stove plants. Make a good group of it and get the full effect of the lovely blue-flowers. Care must be taken that it does not suffer for want of water, and where the pots are full of healthy roots weak liquid manure will be of great assistance to them. Eupatoriums require some-

what similar treatment. These plants if kept a little cooler when in flower will last longer in beauty.

**BOUVARDIAS**

that have ceased to flower should be allowed to rest for a month or six weeks. They should be placed in a light position close to the glass and watering discontinued, removing all leaves as they become yellow.

**ZONAL PELARGONIUMS**

are still in the height of their beauty, and should have every encouragement given them to prolong their flowering season. Watering must be carefully done in the morning. Weak liquid manure and soot water should be given them occasionally. Let the plants have abundance of light and give air whenever possible to keep the atmosphere sweet and dry up superfluous moisture. Do not pour any extra water about the house, as damp and fog are the greatest enemies zonals have in winter.

JOHN FLEMING.

Wexham Park, Slough.

**FORGET-ME-NOT!**

BLUE flowers mirrored themselves in the brook,  
And called to the waves from their sheltered nook:  
"Forget-me-not!"  
The wavelets laughed, "We must haste to the sea,  
And out of sight out of mind will be,  
"Forget-me-not!"

Blue eyes shone in a maiden's face,  
And stole a youth's heart from its hidden place:  
"Forget-me-not!"  
The youth went out in the world so wide,  
Where many a flower bloomed and died;  
"Forget-me-not!"  
And sailing alone o'er the starlit sea,  
There seized him a grief and a memory:  
"Forget-me-not!"  
From the swelling ocean arose a song  
By the drops from the brooklet borne along:  
"Forget-me-not!"

E. M. M.

—(From the German of Julius Wolff.)

**EDITOR'S TABLE.****ROSE MARQUISE DE SALISBURY.**

"G." sends from a Middlesex garden a welcome bunch of flowers of this Rose, which, as many readers are aware, is a Hybrid Tea and deep crimson in colour. This bunch was gathered on the last day of November, and scented the room with its fragrance.

**SWEET PEA LADY GRISEL HAMILTON.**

Some time ago "R. H." sent a gathering of this Sweet Pea, which was described as "a large, beautiful lavender flower," with which remark we fully agree. It is a lovely kind, and we had the bunch photographed, though such illustrations show nothing of the beautiful colouring and fine shape of the flower.

**A STRANGE CYPRIPEDIUM.**

We have received from Mr. W. Y. Baker (of the Thames Bank Iron Company) a strange Cypripedium flower. It has a double labellum or lip, double sepals, and, though not beautiful, is very interesting to those who delight in floral curiosities.

**GARDENING TWO HUNDRED YEARS AGO.**

THERE is one household task which can never be done to satisfaction by a hireling—the arrangement of our books. When a family has been bookish for several generations it becomes no small task, and one is apt to feel impatient when plodding through closets piled with volumes which one can but conclude are mostly what Ruskin calls "books of the hour," and that their hour is long past. But now and then you light on a piece of gold among the dross—something which bears on a subject in which you are interested, or gives a quaint picture of the habits and ideas of a former generation. While dusting the back rows

of books in a long disused schoolroom lately I came upon several interesting old books, one of them a square volume bound in much-battered deep brown leather. "The Compleat English Gardner, or a Sure Guide to Young Planters and Gardeners" is the title, and it proceeds to give a *résumé* of the contents, including "The Ordering of the Garden of Pleasure, with variety of Knots and Wilderness Work after the best and newest Fashion."

It was evidently a popular work in its day, for it is "the Eleventh Edition." As to the authorship we are told it was "begun by Leonard Meager, above Thirty Years a Practitioner in the Art of Gardening, and now enlarged by way of Supplement by a Lover of this Princely Diversion and Profitable Recreation. Printed for M. Wotton at the Three Daggers in Fleet St., and G. Congers at the Ring, in Little Brittain, price 4s."

There is no date on the title-page, but opposite are scrawled in faded ink a variety of names of owners of the book (none of the said names appearing in our family pedigree, I have no idea of the volume's history), and against one of these is the date 1721, which fixes the date of publication at nearly two centuries ago. "Rowland Wood," "John Roks," "Samwell Wheatcroft," "Ben Roe," "Wel Ratelles," and "M. Mosly" are the names, and there are sundry scrawls and hieroglyphics besides. There is a short preface beginning "Reader," recommending the "Compleatness" of the book, disparaging all others on the same subject, and concluding "Farewel S. G."

A list of other books sold "at the Ring" is entertaining. One I should much like to see, a forerunner of Maeterlinck, "The History of Bees, Showing their Admirable Nature, their Government, Loyalty, and Industry, Enemies, Wars, and Magnanimity, together with the right ordering of them." I wonder what the author would have thought of the "ordering" of the ten box-hives into which I have been putting great slabs of peat-flour candy this afternoon! But to return to our list.

"The Way to save Wealth; or How to Live for 2d. a Day." "The Way to get Wealth; by making twenty-three sorts of English Wine equal to French," price 1s. 6d. "Markham's Master-piece, showing how to cure horses, and all sorts of Black and White Cattle," price 4s. "The Experienced Farrier's Jewel," 1s.

The garden is not my department, so I can make little comment on the methods of tree planting, pruning, grafting, &c., but I notice that our author speaks of "inoculating" instead of budding Roses. He gives a catalogue of the fruit trees to be obtained at "Mr. Colchester's, at the Ducking Pond, Clerkenwell Green," and other places. There are five-and-twenty different kinds of Cherries, six "Apricocks," six Figs, including "Blew-spanish"; eleven Grapes, and long lists of Apples and Pears, with quaiut and perfectly obsolete names. What gardener ever heard of a "Davey-gentile" Apple, or "Pig's-tale" Pear? When we come to the list of "Divers pretty flowers fit to furnish a garden" the old names are very amusing. What could "Melan-

FLOWERS OF SWEET PEA LADY GRISEL HAMILTON.

choly Gentleman," have been? "Great Blew Bindweed, or Connvolvulus Major," is more comprehensible. "Lark's-heel, or Spurs—divers varieties," "Spanish Tufts," "Ladies Smocks," "Double Sope-wort, a busie runner in a garden"—as we know to our cost—Munkshood, "Molies," "Flowerdeluces," "Bearsear sanicle," "Sultan's flower, or Turkey Cornflower," "Gilder Roses and Lelacks," and "Jerusalem Cowslips," probably made a pretty show for the ladies of Queen Anne's time.

Chapter VII. is headed "Rare Curiosities in Gardening, being secrets known to very few." "To make a Salad grow from the seed in three or four hours, fit to be cut and brought to table," sounds startling. Ashes of moss and manure were to be worked together, and dried several times in the sun, spread upon an iron plate over a slow fire, and sprinkled with warm rain water. In this you planted seeds of "Purslain or Lettice," that had been soaked in warm water "mixed with dregs of Oyl," and this very rapid crop is said to be the result. "To make Tulips and other flowers of the colour you are pleased to have them," the seeds are to be soaked in dye of the colour desired. "For black, ink; green, verdigrease; yellow, turmeric, &c., sow them in proper ground, and you will find blowing in due time a wonderful change."

"How to produce double Gilliflower of any seed soever." Take a Bean and hollow it, put into it the seed of a single Gilliflower, and stopping the hole with a little soft wax, set it in proper ground, and a Gilliflower will spring out of it, and be double and large.

His faith in Beans seem to have been great. "To make Gilliflower of an extraordinary bigness, you are to mix Bean-flower with the soil."

"To make a Peach tree bear with writing on the fruit." Take the stone of a good bearing Peach, bury it in suitable ground till the stone be half open, so take out the kernel gently, without breaking it, and write on it with vermillion made liquid in the beaten white of an egg, and with a pen write what you please on the kernel; then put the kernel the right way into the shell, and close it with a little soft wax as may just stick it together;

and when it produces a tree-bearing fruit, the words in a lesser or greater measure will appear on the Peaches."

Could anyone have really believed such stuff as this? Yet it is all told with such an engaging confidence and simplicity. Is it possible that a couple of centuries hence our modern books will seem as ridiculous in the eyes of posterity as this does to us?

Our gardener had a greenhouse to preserve his

BAMBUSA TESSELLATA. (From a drawing made at Kew by H. G. Moon.)

"Orange and Limon" trees in winter. This was to have sashes on the south side, and "I approve it rather to be thatched with a thick coat of wheat-straw or fine reeds than to be tiled or slated, for though in a nobleman's or gentleman's garden it is not so sightly, yet it abundantly more keeps out the cold air." "You are to take care that no noisome insects lurk in this house to infest the

plants with their bites or venomous spume, and if you perceive such marks smoothe it with frankincense or storax." This greenhouse was to be heated with "old coal, or charcoal," in a stone-built stove. There is a short chapter on "Prognostics, or Observations on the Moon," directing when to sow and plant. "Prune your Vines when the moon is full, and it is held that neither bird nor insect will infest your Grapes." Would that our Roses and Strawberries could be so easily guarded from these pests!

"When the moon is in Cancer, set and sow all sorts of pulse."

"If you are desirous to have low or dwarf plants, then it is held proper to cut, set and plant in the Wain of the Moon."

Passing over the chapter headed "To order Vineyards," we come to recipes for herb teas and other medical nostrums. "The Roots of White Briony bruised and apply'd of its self to any place where the bones are broken helpe the draw them forth, as also splinters, arrow-heads, and thorns in the flesh." "Hounds tongue is good against the biting of mad dogs, and laid on the bottom of your feet Hounds will not bark at you!"

"Mistletoe hung round the neck, Witches can have no power over you." "Mugwort worn under the soles of your feet you may travel forty mile, and not tire." (Very convenient before the days of cycles!)

"Adder's tongue cureth the biting of an adder. Viper's Bugloss is a remedy against the stings of vipers and other venomous beasts. Arrow-head is good for a wound made with an arrow." How simple it all sounds if one could but believe it! At the end of the book are twenty-four plates — one of sundry primitive-looking tools, one

of a little man in very full knickers and a long-skirted coat inoculating a tree. The rest are plans for gardens, which look more like geometric patterns for chip carving than arrangements of living plants. Some are labelled "Wilderness Worke." I suppose they are in the Dutch taste where—

"Grove nods at grove, each alley has its brother,  
And half the platform just reflects the other."

Poor old book — its day is past — its knowledge has vanished away, but it may afford a brief amusement to some readers who still find pleasure in the "Princely Diversion and Profitable Recreation" of gardening.

MAUDE ROBINSON.

Suddescombe, Brighton.

### BAMBUSA TESSELLATA.

THERE are two hardy Bamboos that stand out conspicuously from all the rest because of the size of their leaves. They are *Bambusa tessellata* and *Bambusa palmata*, both of which have leaves much larger than those of any other hardy species. In *B. tessellata* the largest are 18 inches long and 3½ inches to 4 inches wide, tapering from the middle to a fine point. The upper surface is of a deep lustrous green, whilst the lower one is tinged with a glaucous hue. At one time I was inclined to consider *B. palmata* the best of the large-leaved Bamboos, but now I would give the palm to *B. tessellata*. *B. palmata* is a fine Bamboo, but it scarcely has the graceful character of the present species. Its leaves are neither quite so large as *B. tessellata* nor so tapering, its stems are taller (5 feet to 7 feet), the habit is more erect, and the longitudinal veins of the leaf are more prominent. There is a mass of *B. tessellata* in the Bamboo garden at Kew just now at its best — as green and luxuriant as it was last August. The plant measures about 12 feet across, and the main bulk of its stems and leaves is about 3 feet high, forming a dense mass, the outer stems of which arch outwards to the ground; but rising out of this mass are some of last year's spiky growths, bearing one or two leaves, and these add infinitely to the grace and distinction of the plant.

In many gardens this Bamboo used to be (and may now be) known as *Bambusa* or *Arundo Ragamowski*. This last name is the one under which it was known in English gardens more than fifty years ago. It was probably the first of the hardy Asiatic Bamboos introduced. Thanks mainly to Lord Redesdale's "The Bamboo Garden," the nomenclature of the hardy Bamboos, both in trade and private establishments, is much more satisfactory than it was five years ago.

W. J. BEAN.

### MISCELLANEOUS.

**Chrysanthemum Society of America.** — Pressure on our space at this season of the year has precluded us from making any previous mention of the show and convention held in Chicago on November 12 and 13 by the above-named society. President Herrington occupied the chair, and opened the proceedings by an address, in which he reminded his hearers that the society was organised in 1889 with certain well-defined aims. After reviewing the past and giving particulars of the certificates awarded by the local committees, Mr. Herrington then pressed the claims of the future. He pointed out that the same varieties that are in the cut flower market almost wholly constitute those at the American shows, and pleaded for greater diversity and the creating of the amateur element, which in America appears to be largely lacking. Reference was also made to the system of affiliation existing here in England, and a hope expressed that the American society might in some way adopt it. Various reports were next submitted, and these were followed by a series of papers on various subjects. Only two of these were read at the meeting, one entitled "American Chrysanthemums in England," by Mr. Harman Payne, and the other at the second day's meeting was delivered by Professor Cowell on "The Colour Scheme in Chrysanthemums."

mums." The remainder were unusually numerous, and included (*inter alia*) Border Chrysanthemums, Pompon Chrysanthemums, Foreign Chrysanthemums in America, Hybridising Chrysanthemums, Chrysanthemums in America, History of the Chrysanthemum Society of America, &c., all of which were ordered to be printed in the official account of the proceedings. In the meantime, most if not all of these papers are appearing in the columns of our contemporary the *American Florist*. Indicative of the interest taken in this Chicago show and convention, it may be mentioned that the French National Chrysanthemum Society offered a gold medal for competition, and that our own English National Chrysanthemum Society would unquestionably have done likewise but for the fact that it is face to face with the difficulties consequent upon having to find a new home. The posters announcing the show were of a very attractive and artistic style, as also was the menu of the banquet offered to the visitors by the Chicago Florists' Club. It is expected that a similar gathering will take place next year at New York, where a show was also held this year in the Madison Square Gardens. Messrs. W. Wells and Co., of Earlswood, sent over some very fine blooms, which were much admired by the American growers, and were awarded a silver medal.

**Chrysanthemum audit.** — For some years past Mr. A. Taylor, a member of the executive committee of the National Chrysanthemum Society, has voluntarily taken the trouble to compile an audit of all the varieties shown in the cut bloom classes at the great November show at the Aquarium. At one time he used to give the name of each variety and the number of times that each was shown, but latterly he has unfortunately been unable to present his audit in so complete a form. This is all the more regrettable because for some years past there has been no audit of the kind, either gathered from a series of leading shows or gathered from the National Chrysanthemum Society's show, and thus based upon actual fact. There seems to be nowadays much less interest taken in the winning varieties than there used to be, for even the show reports of the past season were unusually deficient in details of this sort. Consequently those who are chiefly interested in statistical matters have not even the means to prepare an audit for their own use. At the last committee meeting of the National Chrysanthemum Society Mr. Taylor again presented his annual record, which will no doubt in due course appear in the schedule some months hence. In the meantime, however, some readers of THE GARDEN who are interested in the progress of the Chrysanthemum may like to know which way the competition in the cut bloom classes is tending, and so, for comparison, I give the results below as announced by Mr. Taylor:

	1900.	1901.	1902.
Japanese .. .. ..	2,112	2,445	1,787
Incurved .. .. ..	864	657	471
Reflexed .. .. ..	60	48	24
Large Anemone .. .. ..	204	132	108
Anemone Pompon .. .. ..	24	18	12
Pompon .. .. ..	108	54	114
Single .. .. ..	24	24	18
Total .. .. ..	3,396	3,378	2,544

To the two last-named classes, the flowers being staged in bunches, each bunch counts as one bloom. It will be observed that the reduction in the incurved section for this year is immense. So too, of course, is it in the Anemone and reflexed sections, but they never occupied the prominent position once held by the incurves. Of course, many things may be attributed to the season. Sometimes it is too hot, sometimes too dry, sometimes too wet or cold, or early or late, and I know not what beside. But I ask of those who know something about incurved Chrysanthemums is not this reduction very largely due to the present-day practice of including big flat mongrel-bred flowers, without form or comeliness, hallow-eyed, with narrow pointed florets of evident Japanese blood in the stands that were once upon a time conspicuous for the marvellously perfect forms that were then aimed at by grower and raiser alike? And if the old-time standard of excellence

is no longer to be seen at the Aquarium are the same influences at work in the leading provincial shows? Are all the dividing lines to be broken down, and is the day fast approaching when deterioration will so far have developed that not even the greatest expert will be able to tell us the difference between one section and another, for the simple reason that they will all be merged into one conglomerate mass? — C. H. P.

#### French National Chrysanthemum Society.

The seventh annual show and congress of this society was held on November 7 last at Angers, in conjunction with the autumn show of the Horticultural Society of Maine-et-Loire. M. Viger presided at the congress, and announced that M. Dubreuil, the treasurer, and M. Gaston Clément, a well known Parisian Chrysanthemum grower, would both be included in the next list of appointments to the Order of the Mérite Agricole. On the platform there were present Messrs. Maxime de la Rocheterie, Calvat, Bruant Philippe Rivoire, the Secretary, Dubreuil, and others. One of the principal papers was that contributed by M. George Truffaut relative to certain experiments made with various chemical manures on plants of the Chrysanthemum. It was decided that next year's meeting should be held at Lille, and that the one in 1904 should either be in the south or the south-east of France. The medal for meritorious service rendered to the cause was awarded to M. Louis Lacroix of Toulouse, best known perhaps to English growers as the raiser of the variety Vivian Morel. Next day M. Chifflet read a paper on "Diseases and Parasites of the Chrysanthemum." Others equally interesting followed. It was announced that the colour chart would shortly be placed in the printer's hands. The large silver-gilt medal offered for the most interesting paper read at the congress, and which it will be remembered was won last year by Mr. Harman Payne for a paper on the introduction of the Chrysanthemum into France and Europe, was this year awarded to M. Lechat of Sophia, Bulgaria, the author of a capital little cultural manual dealing with the Chrysanthemum and other essays connected with the flower.

## SOCIETIES.

### NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening last the executive committee of the above society held a meeting under the presidency of Mr. Thomas Bevan. Minutes, correspondence, and a considerable amount of routine business occupied the major portion of the evening, which was a very busy and somewhat animated one. The attendance was good, owing to some suggested alterations in the rules, which were likely to have a very decided bearing on the position of the affiliated societies.

A list of medals awarded at the recent December show was read, by which it appeared that the following were made: — Large gold to Messrs. Norman Davis and H. J. Jones; small gold to Messrs. Fleming, H. Cannell and Sons, and C. Black; silver-gilt to Messrs. Forster and Cliburn; large silver to Messrs. Boyce and Co. and Cutbush and Son. A rough interim financial statement was then presented by the secretary, and was generally regarded as indicating a most satisfactory position. Up to the present receipts have come in to the extent of £922 3s. 8d., the expenditure only amounting to £763 8s. 5d., thus leaving a balance in hand of £158 15s. 3d. The accounts, however, are not finally closed, and there are still various sums of receipts and payments to be dealt with before the preparation of the year's balance-sheet.

Specimens of the society's new medal were submitted for inspection. The chairman stated that he hoped very shortly to be able to announce the sites committee's recommendation as to the place where the future shows were to be held.

Mr. A. Taylor, who for some years past has tabulated the blooms shown in the cut bloom classes, read out the result of the November exhibition, which in all sections numbered 2,544, as against 3,378 in 1901, and 3,396 in 1900. A vote of thanks was proposed, and in seconding the motion Mr. Harman Payne referred to the great statistical value of such an audit, which, being based on actual fact, was in his opinion of great value to intending exhibitors, especially if Mr. Taylor could now do as he used to do, namely, give the names of the varieties shown and the number of each.

The meeting closed with the election of new members.

### NATIONAL DAHLIA SOCIETY.

THE annual general meeting of the above society was held, by the kind consent of the Horticultural Club, in their rooms, the Hotel Windsor, Westminster, on Tuesday last, Edward Mawley, Esq., in the chair. Beyond the members of the committee only three others attended. The committee's report, read by the hon. secy., Mr. J. F. Hudson, showed that the exhibition of last autumn was the first

held by the society in London, and that in spite of a very trying and late season, which did keep some members from showing so early as September 2, yet the flowers generally were very good, and the show gave very great satisfaction. Special thanks were due to the council of the Royal Horticultural Society for the privileges afforded in relation to the show, as also for so freely placing at the society's disposal the services of the council's staff. It was shown that whilst in 1901 no less than forty-one certificates were granted to new varieties, largely Cactus forms, that this year only twenty-nine were given out of no less than 112 staged, thus showing that the society was setting up a higher standard of merit than had previously prevailed. Similar arrangements as to next year's show, to be held on September 1 and 2, had been made with the Royal Horticultural Society, for which the committee were exceedingly thankful. A conference on Cactus Dahlia judging will take place on September 1. The treasurer's report showed that the total income of the year was £132 14s. 8d., and the expenditure, which included the payment of every charge, was £127 18s., leaving a balance of £4 16s. 8d. That sum had that day been materially added to.

The chairman congratulated the society on the excellent result of the year's proceedings, in spite of the risk run in moving the show to the Drill Hall. He thought and hoped that next year the attendance would be much larger. Great credit for the excellent financial position was due to the labour of the treasurer, Mr. C. E. Wilkins, strict economy being practised. If the balance was small, at least the society was free from debt. The Royal Horticultural Society's council had behaved most liberally to them, and they had found in the Drill Hall a freedom of action that did not previously exist. He hoped that great efforts would be made next year to make the society and its exhibition known, so as to greatly increase the attendance. He concluded by moving the adoption of the report, which was seconded by Mr. H. Turner, and after a short discussion it was adopted.

The election of officers and committee followed. The patrons are Sir Trevor Lawrence, Bart., V.M.H., Sir J. T. D. Llewelyn, Bart., Baron Schröder, V.M.H., the Earl of Ilchester, the Dean of Rochester, V.M.H., and Leopold de Rothschild, Esq. The patroresses are the Dowager-Duchess of Sutherland, the Countess of Pembroke, the Countess of Lonsdale, Viscountess Sherbrooke, Lady Cynthia Graham, and Miss Ellen Willmott, V.M.H. Mr. E. Mawley was re-elected president, and Messrs. J. T. Bennett-Poe, V.M.H., George Gordon, V.M.H., Thomas Hobbs, F.R.H.S., R. A. Milligan Hogg, F.R.H.S., W. Marshall, F.R.H.S., Dr. M. Masters, F.R.H.S., and J. F. Hudson, vice-presidents. The following constitute the committee, the only new name added being that of Mr. E. T. Cook: T. Antiss, W. Baxter, F.R.H.S., H. S. Boby, F.R.H.S., H. L. Brousson, J. Burrell, F.R.H.S., H. Cannell, F.R.H.S., J. Cheal, F.R.H.S., E. T. Cook, A. Dean, F.R.H.S., F. W. Fellowes, R. Fife, F.R.H.S., J. T. Frost, F.R.H.S., J. Green, F.R.H.S., J. Hepshaw, J. Hudson, V.M.H., G. Humphries, F.R.H.S., H. J. Jones, F.R.H.S., S. Mortimer, F.R.H.S., H. A. Needs, Rev. S. S. Pearce, F. W. Seale, J. Stredwick, E. F. Such, A. Taylor, J. R. Tranter, F.R.H.S., W. Treseider, F.R.H.S., H. Turner, V.M.H., J. Walker, F.R.H.S., J. T. West, F.R.H.S., and C. G. Wyatt.

Mr. J. F. Hudson having intimated that he could not continue to act as hon. secretary in consequence of the pressure of duties elsewhere, Mr. T. W. Tulloch, of Hove, Sussex, was elected to the office. A cordial vote of thanks was awarded to Mr. Hudson for his long and valued services. Mr. C. E. Wilkins was re-elected treasurer, and was also cordially thanked, as also was Mr. Edward Mawley later for his eminent services to the society as president. It was agreed that the annual general meeting be held on the third Tuesday in December of each year. A request from Manchester for an exhibition of Dahlias by the society was discussed, and remitted to the committee under certain conditions. Mr. A. Dean spoke strongly in favour of the society being formed with the Royal Horticultural Society in a trial of new Cactus Dahlias at Chiswick of varieties specially fitted for garden decoration, and Mr. Tulloch urged the consideration of his proposal in a circular issued to the members of the provision of challenge cups for both traders and amateurs for collections of Cactus Dahlias at the annual exhibition.

### KIDDERMINSTER AND DISTRICT HORTICULTURAL SOCIETY.

#### "DIGGING AND TRENCHING."

THIS was the title of a practical and instructive address by Mr. W. H. Wilson, head gardener to John Brinton, Esq., Moor Hall, Stourport, before the members of this society on the 10th inst. Mr. C. Dalley presided over a good attendance. The lecturer dealt with his subject in a free and conversational manner, and gave the members the benefit of his practical experience acquired on a variety of soils in different parts of the country. An interesting discussion followed, and Mr. Wilson was warmly thanked for his most interesting lecture. The programme for 1903 is now being arranged, and will shortly be issued to members.

### READING AND DISTRICT GARDENERS' ASSOCIATION.

At the last fortnightly meeting of this association Mr. W. Tribick, of Brooke Gardens, Isle of Wight, read a most interesting and practical paper on "The Cultivation of Peaches and Nectarines." The opening portion treated of the origin, history, and most prominent characteristics of the fruits, and this was followed by cultural details under the following headings: Position, soil, time of planting, disudding, watering, ventilation, bud dropping, winter work in houses, manures, diseases, and varieties. A good discussion followed, in which Messrs. Hinton, Neve, Woolford, Blake, Powell, Clinch, Stanton, Alexander, Fry, and Bright took part. The exhibits were not numerous, but one was of exceptional interest, viz., a punnet of Red Currants shown

by Mr. F. Bright, of Whiteknights Park, picked on the same day from the open. The fruits were in splendid condition, of good size, and equal to those usually gathered in July. Mr. Hinton, of Walmer Gardens, exhibited several vases of single Chrysanthemums.

## ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—DECEMBER 9.

PRESENT: Dr. M. T. Masters (in the chair), Messrs. Douglas, Gordon, Hudson, Veitch, Saunders, Bowles, and Worsdell, Dr. Cooke, Revs. W. Wilks and G. Henslow, hon. sec.

*Dr. M. C. Cooke, V.M.H.*—Dr. Masters rose and said he had much pleasure, in which he was quite sure the committee would join, in handing the gold medal to Dr. Cooke, to whom the council of the society had assigned it. Dr. Cooke expressed his thanks for the same.

*Carnation leaves rooting.*—Mr. Douglas observed, with regard to a remark of Mr. Massee's, that roots sometimes occur on the leaves when the roots were affected. That in the case of those he had exhibited the roots were perfectly sound, and he could suggest no cause for the appearance of the roots on the leaves.

*Nephrolepis tuberosa.*—Mr. Saunders exhibited some of the tubers found on the roots of this plant. They did not appear to have "eyes" or buds upon them, so as to be propagative. It was suggested that their use may be for water storage only.

*Celaric disease.*—Specimens were sent by Mr. Kitson, The Chantry, Netherbury. Dr. Cooke undertook to examine and report upon them.

*Hyacinth bulbs diseased.*—Mr. Saunders gave the following report upon the bulbs sent to the last meeting:—"A hyacinth bulb, which was very much decayed, was shown at the last meeting of the Royal Horticultural Society's scientific committee. The bulb contained any number of the bulb mite, *Rhizoglyphus echinophagii*, and these mites were no doubt the cause of the injury to the bulb. Besides the mites there was a quantity of a greenish mould, which I imagine only began to grow on the bulb after it had been killed by the mites. When bulbs are infested with these mites in the manner that this one was, nothing can be done, as far as I know, to save them. When only a few mites are at the base of the bulb—where the attack generally commences—they may be killed by immersing the bulbs for five minutes in water at a temperature of 115° or 120 Fahr. If some sulphide of potassium (6oz. to a pint) was added to the water, this remedy would be all the more efficacious; indeed, it is said that soaking the bulbs in this solution cold for twenty minutes will kill the mites. It is very essential that any of the soil from pots which has contained bulbs infested by this pest should not be allowed to get mixed with fresh soil on the potting bench or elsewhere." Dr. M. C. Cooke added the following observations:—"Such a profuse crop of saprophytic moulds, as *Penicillium*, that they effectively mask the disease, whatever it may be, and there are plentiful *Acaris* present."

*Dicentra Fraxinella.*—Mr. Bowles referred to the germination of the seeds of this plant, as they were sown as soon as ripe, but did not germinate. Mr. Wilks observed that the seeds will not germinate if kept any time out of the ground, so that it was thought they may have been overwatered. Mr. Wilks added that the best procedure is to sow them at once in a pan with a tile over it touching the earth till required to be planted out.

*Physiological experiment.*—Mr. Henslow described an experiment he had carried out with two objects in view. The first was to ascertain if darkness had any effect upon the direction of growth of roots. He grew some Mustard on a perforated tin over a glass of water, the latter having black paper pasted all over it, excepting a narrow strip facing the light, which could fall upon the roots in the water. They, however, grew vertically downwards, uninfluenced under these conditions by either light or darkness. The second object was to see if water arrested the growth of the primary root, as in paper on "A Theoretical Origin of Monocotyledons from Aquatic Dicotyledons" (Journ. Linn. Soc., vol. xxix., page 486), he had inferred from the great number of coincidences, both in morphology and anatomy, that such must have been the case. One such agreement was the total arrest of the axial root in all Monocotyledons and also in aquatic Dicotyledons, as *Ranunculus aquatilis*, *Tripa*, *Ceratophyllum*, *Victoria regia*, &c. Such proved to be the case with Mustard. The conical extremity of the tap-root became brown and died, while strong secondary roots with root-hairs arose from the periphery of the point just above the dead apex. This experimental verification thus corroborated the above induction.

## NATIONAL AURICULA AND PRIMULA SOCIETY.

The annual general meeting of the supporters of this society took place at the Horticultural Club, Hotel Windsor, on the 13th inst., Mr. E. Colby Sharpin, one of the vice-presidents, occupying the chair, there being a fair attendance. The annual report, presented by the secretary, Mr. T. E. Henwood, set forth that the exhibition in the present year was one of the largest ever held, and that the sum of £11 6s. was paid in prizes in excess of those of the previous year, so good was the competition generally. Eight members have lapsed through death and other causes, among them one subscriber of £5, but ten new members had been added. As the balance in the hands of the treasurer is small a reduction in the prize money was recommended in order to remove any danger of the balance in hand being wiped out next year. The balance sheet showed an income of £92 6s., including £21 13s. 6d. brought over from last year. The expenditure had been £55 19s. 4d., which included £C9 12s. paid as prize money, a balance in the hands of the treasurer of £6 6s. 8d. being carried forward. The report and balance-sheet were adopted. Some reductions in the amounts of the prizes in several classes were made to the amount of £8, this being deemed

inevitable in the face of the society's reduced balance. In the course of revising the schedule of prizes it was announced that class 10 for six green-edged Auriculas in not less than three varieties and not more than two of one variety, would read grey edges instead of green edges. Some conversation took place as to the pin-eyed character of some of the new varieties of alpines, and it was reported that on the occasion of the Midland Auricula show at Birmingham this year a resolution was passed affirming the importance of the judges of Auriculas asserting the old principle that a protruding style should be a disqualification. Class 31 was made to read, instead of basket of Primroses and Polyanthus, a collection staged on a table space of 4 feet by 3 feet, the plants in or out of pots. Sir John T. D. Llewelyn, Bart., was re-elected president, and the vice-presidents were re-elected, with the addition of the name of Mr. J. W. Bentley, Stakehill, Manchester. Messrs. F. A. Wellesley, J. Sargent, and S. Mortimer were elected on the committee, and Mr. T. E. Henwood was re-elected honorary secretary and treasurer, with many thanks for his valuable services to the society. A vote of thanks was passed to the chairman for presiding.

## NATIONAL CARNATION AND PICOTEE SOCIETY.

The annual general meeting of the members of this society took place at the Horticultural Club, Hotel Windsor, on the 13th inst., Mr. E. Colby Sharpin, the chairman of the committee, presiding, in the absence of the president, Mr. Martin R. Smith, who, it was reported, is abroad for the benefit of his health. There was a good attendance of the leading supporters of the society, including Messrs. F. A. Wellesley, E. Charrington, H. Turner, A. W. Jones (Birmingham), A. J. Rowberry, C. Bick, W. L. Walker (Reading), J. Sargent, &c. The annual report set forth that the society was in a thoroughly sound and satisfactory character, and though 45 members had been lost to the society during the year from death and other causes, 47 new members had been obtained, being two to the good. In view of the balance in hand having been reduced in 1901, the prize money offered in 1902 was reduced in a few particulars, with the result that the income had exceeded the expenditure by £6, although a considerably larger sum had been paid for printing, owing to the demand made for copies of the annual report for 1902, which included a report from Mr. M. R. Smith on "Manning Carnations," and this had necessitated a reprint of the paper and schedules. The balance-sheet showed that, including the sum of £119 10s. 6d. brought over from last year, the total income for the year was £358 11s.; subscriptions amounted to £229 6s. 6d., the expenditure included £125 11s., paid in prizes, printing, &c., £58 7s. 5s., leaving a balance in hand of £125 15s. 10d., a statement which was considered very satisfactory. Mr. Martin R. Smith was re-elected president, the names of Messrs. M. Rowan (who is retiring from the committee on account of ill-health, and who was alluded to by one speaker as "the Grand Old Man of Carnation culture") and V. Charrington were added to the vice-presidents, and a proportion of the outgoing members of the committee, with the exception of two or three who had resigned, were re-elected, together with new additions in the persons of Mr. A. J. Rowberry and J. J. Sheldon. The floral committee were also re-elected, with the exception of Mr. Weir, who retires; and new members were added in the persons of Messrs. W. Spencer, jun., and E. Charrington, the number being increased to seven.

A communication was read from Mr. B. J. W. Grieve to the effect that, having regard to the financial position of the society, the pruning knife should be applied to the schedule of prizes and the number reduced to two only in each class. He also made complaint that the judging in Division IV., at the last show was bad, prizes having been awarded to dressed flowers which were staged as undressed blooms, and suggested that every encouragement should be given to undressed flowers, especially in the interests of amateurs who are not skilled in the art of dressing, and that the use of cards and collars should be disallowed. It was agreed that the attention of the judges should be given to the close examination of the calyxes; and the following addition to the regulations was adopted: "There must be no manipulation of the calyx; a split calyx will be a disqualification." It was further resolved that in Classes 10, 24, and 34, the words "Carnations, selfs and fancies," should read "Selfs, fancies, and yellow grounds," the term Carnations being deleted. It was suggested that application be made to the Royal Horticultural Society for permission to have small supplemental exhibitions of Carnations at the Drill Hall; and it was agreed that if it can be arranged one exhibition should be held a fortnight before and a second a fortnight after the annual exhibition of the society, which is fixed for July 21, 1903. A new class is to be added to Division IV., to follow Class 39, for three blooms each of six varieties, shown in bottles, the wording to be the same as in Class 10; and five prizes were allotted, as also the points the blooms would carry. An additional class was framed to follow the foregoing for single blooms of any colour, prizes and points being also allotted. The two last prizes in the classes in Division IV. were withdrawn to supply the prize money in the new classes. The method of awarding certificates of merit to new varieties came in for some sharp criticism, and on the motion of Mr. F. A. Wellesley, seconded by Mr. A. W. Jones, it was resolved that "The granting of certificates of merit shall be the work of the floral committee, and it shall be an instruction to that committee that when awarding certificates the variety shall also be classified. The judging of new varieties to take place after the judges' luncheon." It was understood that application would be made to the Royal Horticultural Society for a table to be set apart at which the floral committee would sit, and all new varieties would be brought to the table. No one but the members of the floral committee would be permitted to be near the table at the time. It would obviously be a great advantage to the representatives of the gardening Press if awards to new varieties were made before and not after luncheon. The proceedings concluded with a hearty vote of thanks to the chairman for presiding.

ANSWERS  
TO CORRESPONDENTS.

**Palms from seed** (SIR GROFTON HOE).—It is quite possible to grow Palms from seed; indeed, that is the only method available for increasing this class of plants. The best way to get

pretty little plants in 2½-inch pots is to sow the seed in a pot or pan, and as soon as the first leaf is about an inch long put them singly into 2½-inch pots. A good soil is one-half yellow loam to an equal amount of peat or well-decayed leaf-mould, and

a liberal dash of sand. The young plant should be potted at such a depth that the seed just rests on the surface of the soil. This will in time decay and fall off. The seeds even of the greenhouse Palms will grow better if kept in a stove temperature during their earlier stages. I have some plants of Kentia forsteriana that were sown nearly four years ago, and potted off as above detailed. They are now pretty little plants, still in the same pots, and have been in the dwelling-house for over two years. Some of the best Palms for this purpose are Kentia belmoreana, Kentia forsteriana, Cocos weddelliana, and Geonoma gracilis. These seeds are often sent to this country in large numbers, but the reason that they are seldom mentioned in nurserymen's catalogues is, that they retain their vitality for but a short time, and consequently need to be sown as soon as possible after arrival. A note to any of the principal nurserymen will ensure a list of Palm seeds that they have in stock, or when others may be expected.—H. P.

**Shirley Poppies** (P.).—You must sow seed of these in spring, and sow thinly. Get the seed from a good source.

SHIRLEY POPPIES.

## QUESTION.

**The use of climbers.**—In a recent issue of THE GARDEN, your correspondent "E. K. R." discourses pleasantly of the beauty of climbers planted so as to "fling their wreathed wealth of blossom" in "free life among the branches of a growing tree." We shall all agree. But will he or you tell us how it is done? I for one have tried a good many times with strong-growing Roses and Honeysuckles and such like so far without success. Plant your climber close to the stem of the growing tree, and it is starved by the tree roots and weakened by lack of sun. Plant it outside the sweep of the boughs and it has to be guided upwards with an elaborate arrangement of Hop-poles or fishing-rods, and its lower length is not only bare and unsightly, but an awkward block on the lawn. Is there a better and safer middle way, and if so, what?—DUNDEE RAMBLER. [Would some reader who has grown Roses against trees kindly help our correspondent?—E. J.]

## BOOKS, &amp;c., RECEIVED.

*The Englishwoman's Year Book* is in its twenty-third year, and is edited by Emily Jones, organising secretary to the National Union of Women Workers of Great Britain and Ireland. It is an excellent publication. It is published by Adam and Charles Black, Soho Square, price 5s.

*New Bulletin of Miscellaneous Information.*—We have received Appendix I. for 1903. It contains a list of seeds of hardy herbaceous plants and of trees and shrubs which for the most part have ripened at Kew during 1902. These seeds are available only for exchange with botanic gardens and with regular correspondents. No application, except from remote Colonial possessions, can be entertained after the end of March.
